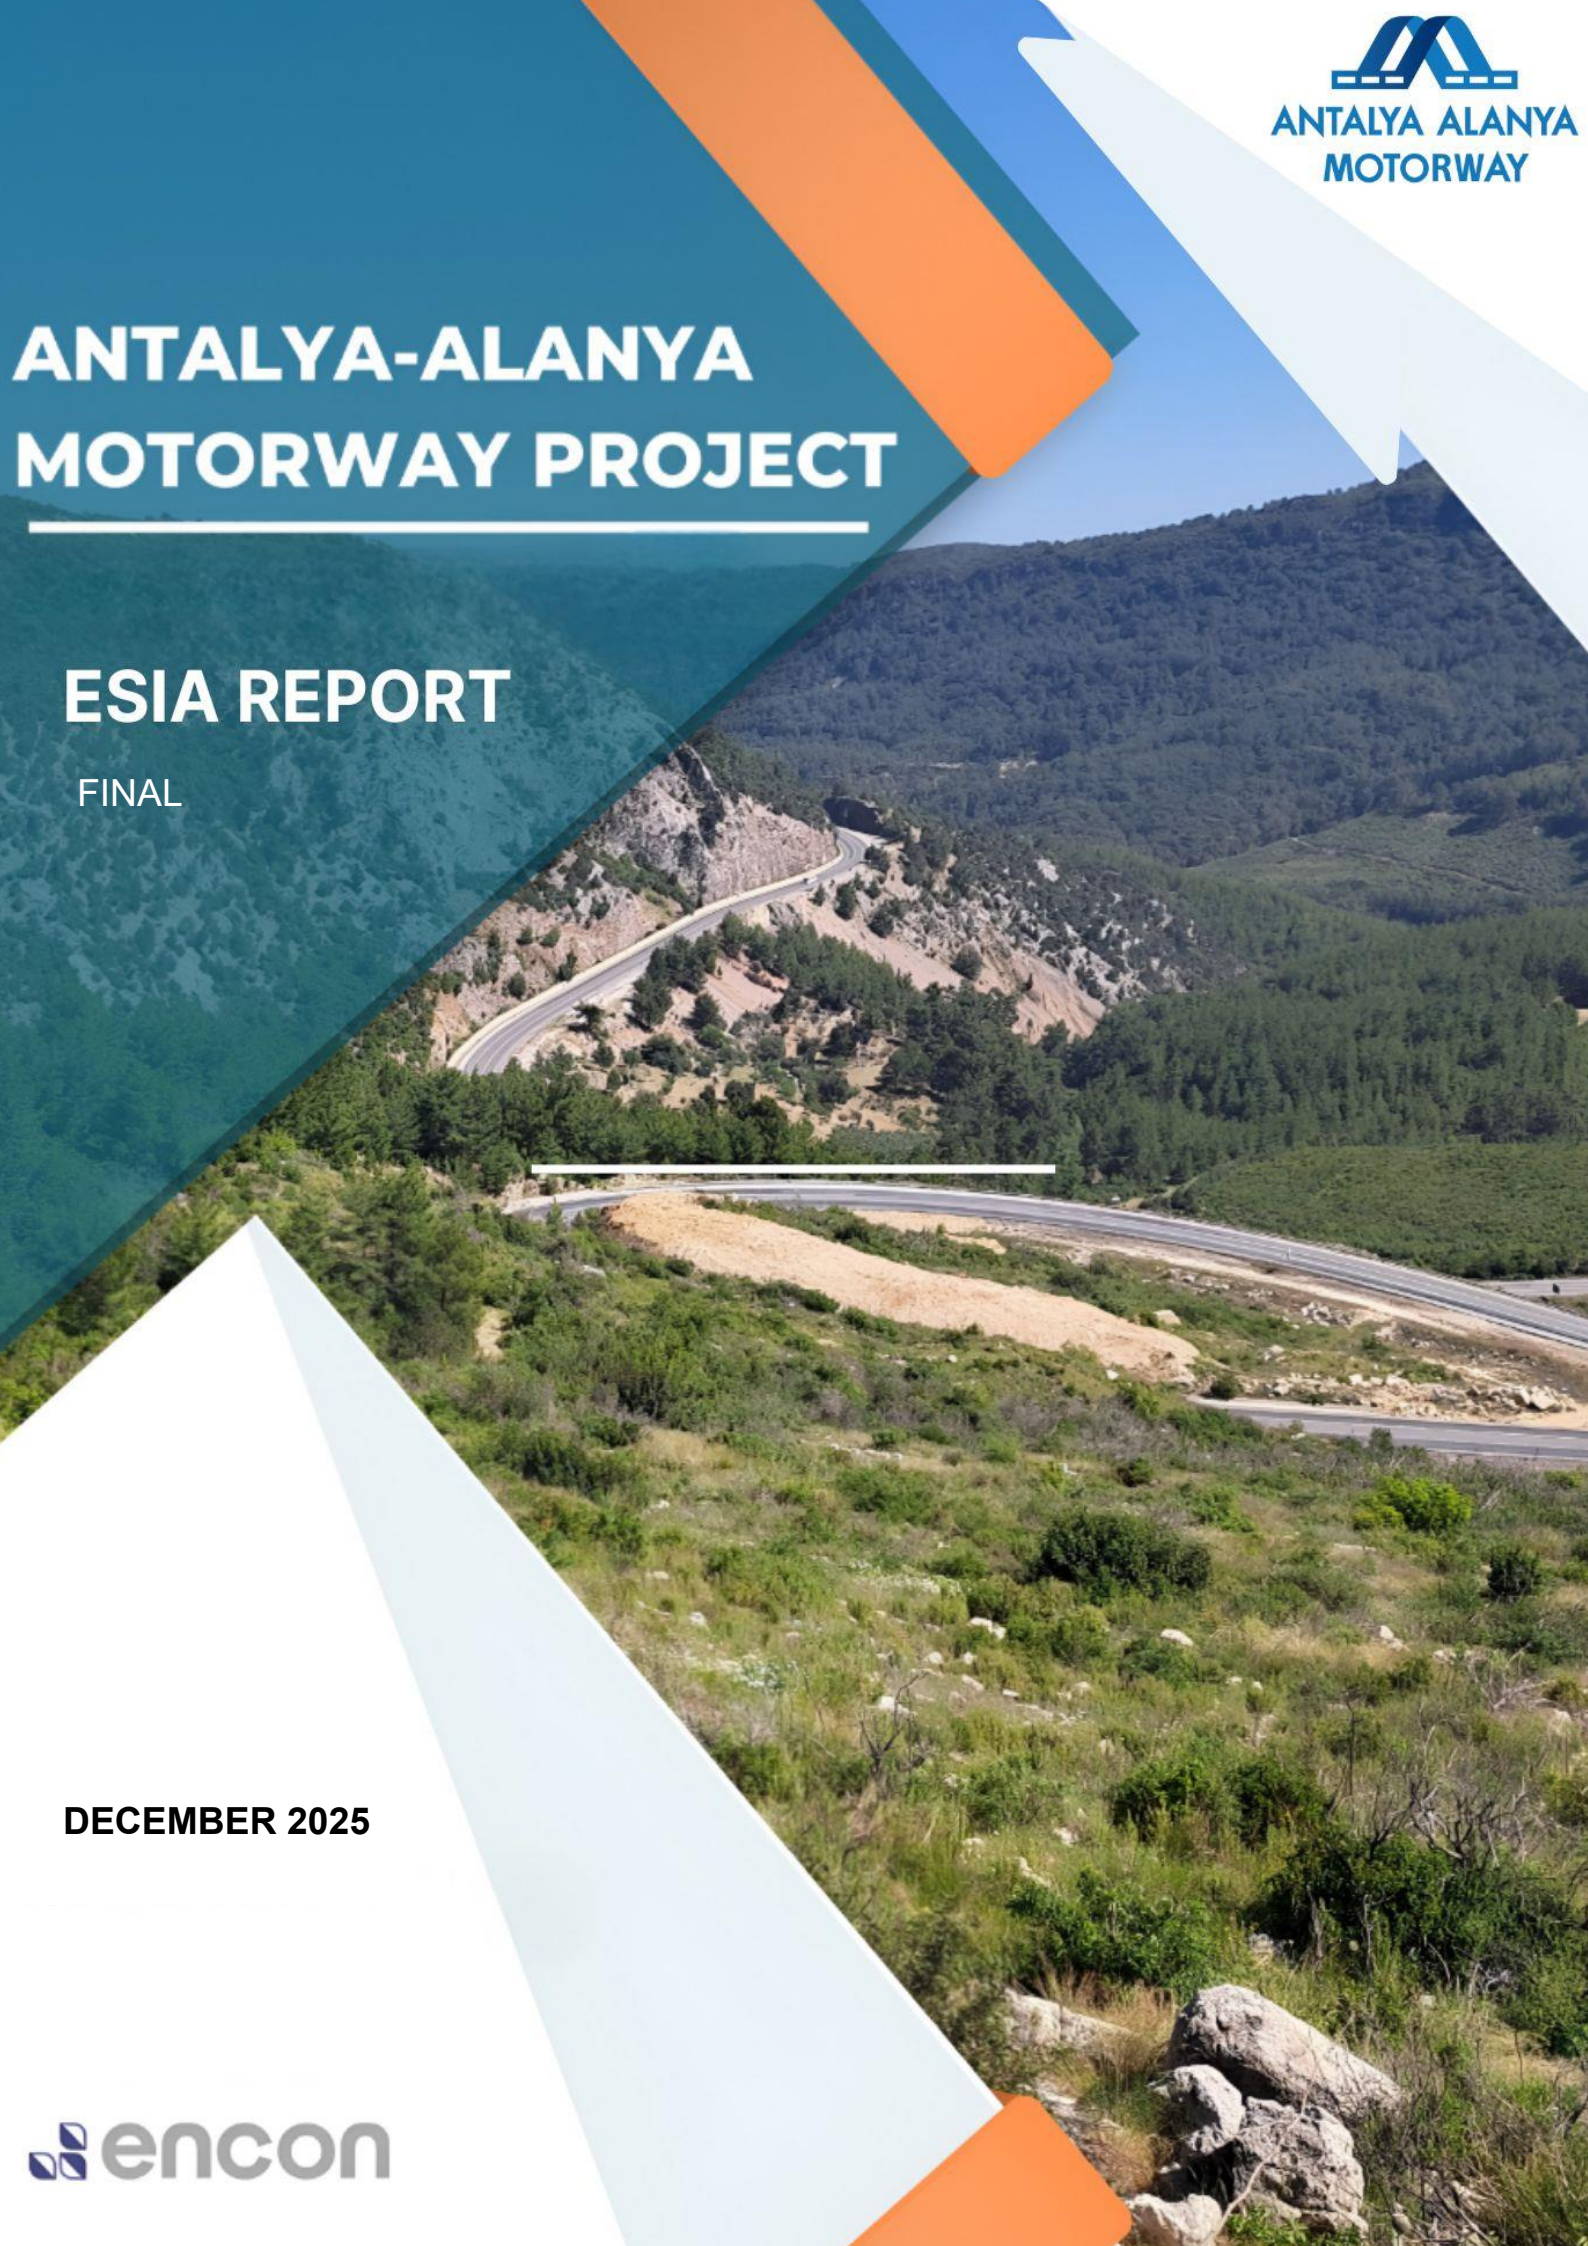
ANTALYA ALANYA MOTORWAY

ANTALYA-ALANYA MOTORWAY PROJECT

ESIA REPORT

FINAL



DECEMBER 2025

encon

REVISION HISTORY

Rev.	Date of Issue	Issue Reason	Prepared by	Reviewed by	Approved by
1	September 2024	First submission	B.U. E.K. G.A. M.E.C. N.D.Y. O.A. O.O. U.S.	N.D.Y.	T.B.
2	November 2024	Incorporation of Project Sponsor's comments	B.U. E.K. G.A. M.E.C. N.D.Y. O.A. O.O. U.S.	N.D.Y.	T.B.
3	April 2025	Revision made to reflect updates due to changes in the project route and inclusion of newly obtained data	B.U. O.O. C.O. E.D. E.K. G.A. M.E.C. N.D.Y. O.A. O.C.K. S.A. U.S.	N.D.Y.	T.B.
4	May 2025	Revision made to reflect updates due to changes in the project route and inclusion of newly obtained data	B.U. O.O. C.O. E.D. E.K. G.A. M.E.C. N.D.Y. O.A. O.C.K. S.A. U.S.	N.D.Y.	T.B.
5	May 2025	Revisions in line with the Initial Findings specified by the Lender consultant	B.U. O.O. C.O. E.D. E.K. G.A. M.E.C. N.D.Y. O.A. O.C.K. S.A. U.S.	N.D.Y.	T.B.
6	June 2025	Revisions made under ESDD submitted by the Lender consultant	B.U. O.O.	N.D.Y.	T.B.

Rev.	Date of Issue	Issue Reason	Prepared by	Reviewed by	Approved by
			C.O. E.D. E.K. G.A. M.E.C. N.D.Y. O.A. O.C.K. S.A. U.S.		
7	July 2025	Revisions made under ESDD submitted by the Lender consultant	B.U. O.O. C.O. E.D. E.K. G.A. M.E.C. N.D.Y. O.A. O.C.K. S.A. U.S.	N.D.Y.	T.B.
8	September 2025	Revisions made under ESDD submitted by the Lender consultant	B.U. O.O. C.O. E.D. E.K. G.A. M.E.C. N.D.Y. O.A. O.C.K. S.A. U.S.	N.D.Y.	T.B.

TABLE OF CONTENTS

REVISION HISTORY 2
TABLE OF CONTENTS 4
List of Tables 12
I.INTRODUCTION 1
I.1. Aim of the ESIA Report 3
I.2. Need for and Aim of the Project 4
I.3. Background to the Project 8
II. INSTITUTIONAL AND LEGAL FRAMEWORK 10
II.1. Institutional Framework 10
II.1.1. Central Administrations 12
II.1.2. Provincial, Regional and District Level Administrations 13
II.1.3. Local Administrations 14
II.2. Applicable Turkish Environmental and Social Legislation 14
II.2.1. EIA Process under Turkish EIA Regulation 18
II.2.2. Expropriation Process under Turkish Expropriation Law 20
II.2.3. Resettlement Process under Turkish Resettlement Law 21
II.2.4. Cultural Heritage Management under Conservation of Cultural and Natural Assets Law 23
II.3. Relevant International Agreements and Protocols 24
II.4. Applicable International Environmental and Social Standards and Guidelines 25
II.4.1. Equator Principles IV 26
II.4.2. IFC Standards and Guidelines 28
II.4.3. EU Directives 32
II.4.4. AIIB Environmental and Social Framework 33
II.4.5. Other Applicable Standards and Guidelines 33
II.4.6. Project Categorization 34
II.5. Project Standards 35
II.6. Permits 43
III. PROJECT DESCRIPTION 49
III.1. Project Design Criteria 49
III.2. Description of Activities and Project Components 54
III.2.1. Construction Camp Sites and Quarries 55
III.2.2. Storage Sites 66
III.2.3. Engineering Structures 67
III.2.4. Temporary Access Roads 75
III.2.5. Toll Collection Areas 89
III.2.6. Service Areas 89
III.2.7. Maintenance and Operation Centers 90
III.2.8. Pavement Structure 91
III.3. Expropriation Corridor 93

III.4. Description of the Route 93
III.5. Workforce 96
III.6. Construction Machinery 97
III.7. Materials to be used 97
III.8. Traffic Projections 98
III.9. Implementation Program 101
III.10. Project Cost and Incomes 103
IV. ESIA METHODOLOGY 105
V. LAND USE AND PROPERTY 119
V.1. Assessment Methodology and Data Sources 119
V.2. Baseline Conditions 120
V.2.1. Land Use Characteristics within the Study Area 121
V.2.2. Property and Ownership within the Expropriation Corridor 163
V.3. Potential Impacts 163
V.3.1. Land Preparation and Construction Phase 164
V.3.2. Operation Phase 176
V.4. Mitigation Measures 177
V.4.1. Land Preparation and Construction Phase 177
V.4.2. Operation Phase 182
V.5. Summary of Assessment and Residual Impacts 182
VI. TOPOGRAPHY, SOILS, AND GEOLOGY 187
VI.1. Assessment Methodology and Data Sources 187
VI.2. Baseline Conditions 188
VI.2.1. Topography and Soils 188
VI.2.2. Topographical Conditions 188
VI.2.3. Geology 226
VI.3. Potential Impacts 270
VI.3.1. Land Preparation and Construction Phase 270
VI.3.2. Operation Phase 277
VI.4. Mitigation Measures 278
VI.4.1. Land Preparation and Construction Phase 278
VI.4.2. Operation Phase 281
VI.5. Summary of Assessments and Residual Impacts 283
VII. USE OF RESOURCES AND WASTE MANAGEMENT 289
VII.1. Assessment Methodology and Data Sources 289
VII.2. Baseline Conditions 290
VII.2.1. Quarries and Material Borrow Sites 290
VII.2.2. Existing Waste Management Infrastructure in the Region 292
VII.3. Potential Impacts 294
VII.3.1. Land Preparation and Construction Phase 295
VII.3.2. Operation Phase 306

VII.4. Mitigation Measures 307
VII.4.1. Land Preparation and Construction Phase 308
VII.4.2. Operation Phase 313
VII.5. Summary of Assessments and Residual Impacts 313
VIII. WATER RESOURCES 316
VIII.1. Assessment Methodology and Data Sources 316
VIII.2. Baseline Conditions 316
VIII.2.1. Antalya Basin 317
VIII.2.2. Water Resources 320
VIII.2.3. Field Surveys and Findings 333
VIII.2.4. Wastewater Management 358
VIII.3. Potential Impacts 360
VIII.3.1. Land Preparation and Construction Phase 360
VIII.3.2. Operation Phase 361
VIII.4. Mitigation Measures 362
VIII.4.1. Design Phase 362
VIII.4.2. Land Preparation and Construction Phase 363
VIII.4.3. Operation Phase 365
VIII.5. Summary of Assessment and Residual Impacts 366
IX. ECOLOGY AND BIODIVERSITY 370
IX.1. Baseline Data Collection 370
IX.2. Legal Framework and Reference Standards 371
IX.2.1. International Agreements 371
IX.2.2. Turkish Legal Requirements 373
IX.2.3. Standards and Guidelines for International Requirements 375
IX.3. Ecological Baseline Research 377
IX.3.1. Definition of the Study Area and Area of Influence 379
IX.3.2. Internationally Recognized Areas within the Region of the Project Area 393
IX.4. Methodology of Biodiversity Surveys 396
IX.4.1. Terrestrial Biodiversity 396
IX.4.2. Aquatic Environment 401
IX.4.3. Significance Criteria 403
IX.4.4. Critical Habitat Assessment Process 405
IX.4.5. Ecologically Appropriate Area of Analysis (EAAA) 406
IX.5. Findings for Ecology and Biodiversity 407
IX.5.1. Natural and Modified Habitats 407
IX.5.2. Terrestrial Flora 419
IX.5.3. Terrestrial Fauna 421
IX.5.4. Aquatic Environment 436
IX.5.5. Invasive Species 443
IX.6. Critical Habitat Assesment 443

IX.6.1. Summary of Critical Habitat Features 447
IX.6.2. Ecology of Species Triggering Critical Habitat 448
IX.1. Habitats and Species of Conservation Importance 451
IX.7. Impact Assessment 452
IX.7.1. Significant Receptors 453
IX.7.2. Construction Phase Impacts on Ecology 464
IX.7.3. Operation Phase Impacts on Ecology 472
IX.8. Mitigation Measures 478
IX.8.1. Construction Phase 479
IX.8.2. Operation Phase 483
IX.8.3. Risk-Impact-Measure Matrix 484
IX.8.4. Monitoring 484
IX.8.5. Summary of Assessment and Residual Impacts 489
IX.9. Ecosystem Services 495
IX.9.1. Provisioning Services 496
IX.9.2. Regulating Services 496
IX.9.3. Cultural Services 496
IX.9.4. Supporting Services 497
IX.10. Summary of Ecology and Biodiversity 497
X. AIR QUALITY AND CLIMATE CHANGE 499
X.1. Air Quality 499
X.1.1. Assessment Methodology and Data Sources 500
X.1.2. Baseline Conditions 506
X.1.3. Potential Impacts 513
X.1.4. Mitigation Measures 575
X.1.5. Summary of Assessments and Residual Impacts 577
X.2. Climate Change 577
X.2.1. Assessment Methodology and Data Sources 578
X.2.2. Baseline Conditions 586
X.2.3. Potential Impacts 614
X.2.4. Mitigation Measures 633
X.2.5. Summary of Assessment and Residual Impact 634
XI. NOISE AND VIBRATION 638
XI.1. Noise 638
XI.1.1. Assessment Methodology and Data Sources 639
XI.1.2. Baseline Conditions 642
XI.1.3. Potential Impacts 650
XI.1.4. Mitigation Measures 686
XI.1.5. Summary of Assessment and Residual Impacts 688
XI.2. Vibration 688
XI.2.1. Assessment Methodology and Data Sources 689

XI.2.2. Baseline Conditions 693
XI.2.3. Potential Impacts 693
XI.2.4. Mitigation Measures 723
XI.2.5. Summary of Assessment and Residual Impacts 727
XII. CHAPTER – PROTECTED AREAS, LANDSCAPE AND VISUAL ENVIRONMENT 732
XII.1. Protected Areas 732
XII.1.1. Baseline Conditions 732
XII.1.2. Potential Impacts and Mitigation Measures 744
XII.2. Landscape and Visual Environment 744
XII.2.1. Assessment Methodology and Data Sources 745
XII.2.2. Baseline Conditions 745
XII.2.3. Visibility Analysis 747
XII.2.4. Potential Impacts and Mitigation Measures 751
XIII. ARCHAEOLOGICAL AND IMMOVABLE CULTURAL HERITAGE 757
XIII.1. Assessment Methodology and Data Sources 758
XIII.1.1. Regulatory Requirements 758
XIII.1.2. Methodological approach 760
XIII.2. Baseline Conditions 770
XIII.2.1. Historical Geography of the Region 770
XIII.2.2. Archaeological Findings of Antalya Province 772
XIII.2.3. Tangible Cultural Heritage 777
XIII.2.4. Intangible Cultural Heritage 822
XIII.3. Potential Impacts 831
XIII.3.1. Land Preparation and Construction Phase 833
XIII.3.2. Operation Phase 866
XIII.3.3. Decommissioning and Closure Phase 867
XIII.4. Mitigation Measures 867
XIII.5. Summary of Assessment and Residual Impacts 872
XIII.5.1. Residual Impacts 873
XIII.5.2. Monitoring 873
XIV. SOCIO-ECONOMIC ENVIRONMENT 912
XIV.1.1. Assessment Methodology and Data Sources 912
XIV.1.2. Significance Criteria 912
XIV.1.3. Data Sources 915
XIV.2. Baseline Conditions 921
XIV.2.1. Population 922
XIV.2.2. Education 925
XIV.2.3. Health Status 932
XIV.2.4. Socio-economic Baseline and Project-Affected People by Settlement 939
XIV.2.5. Ecosystem Services Review 944
XIV.3. Social Impact Baseline and Risk Analysis 945

XIV.3.1. Human Rights Assessments 945
XIV.3.1.1. Methodology 945
XIV.3.2. Vulnerability Assessment 947
XIV.3.3. Gender Assessment 954
XIV.3.4. Ecosystem Services 954
XIV.4. Potential Impacts 955
XIV.4.1. Land Preparation and Construction Phase 956
XIV.4.2. Operation Phase 963
XIV.5. Mitigation Measures 965
XIV.5.1. Land Preparation and Construction Phase 965
XIV.5.2. Operation Phase 969
XIV.6. Summary of Assessment and Residual Impacts 971
XV. CHAPTER - COMMUNITY, HEALTH AND SAFETY 977
XV.1. Assessment Methodology and Data Sources 977
XV.2. Baseline Conditions 979
XV.3. Potential Impacts 992
XV.3.1. Land Preparation and Construction Phase 994
XV.3.2. Operation Phase 1001
XV.4. Mitigation Measures 1003
XV.4.1. Land Preparation and Construction Phase 1004
XV.4.2. Operation Phase 1013
XV.5. Summary of Assessment and Residual Impacts 1020
XVI. LABOR AND WORKING CONDITIONS 1025
XVI.1. Assessment Methodology and Data Sources 1025
XVI.2. Baseline Conditions 1027
XVI.3. Potential Impacts 1030
XVI.3.1. Land Preparation and Construction Phase 1031
XVI.3.2. Operation Phase 1034
XVI.4. Mitigation Measures 1037
XVI.4.1. Land Preparation and Construction Phases 1037
XVI.4.2. Operation Phase 1052
XVI.5. Summary of Assessment and Residual Impacts 1055
XVII. CUMULATIVE IMPACT ASSESSMENT 1060
XVII.1. Definitions, Methodology Assessment and Data Sources 1060
XVII.1.1. Definitions 1060
XVII.1.2. Cumulative Impact Assessment Methodology 1062
XVII.2. Potential Impacts 1071
XVIII. ANALYSIS OF ALTERNATIVES 1089
XVIII.1. Route Selection Alternatives 1089
XVIII.1.1. Alternative Route Selection during Feasibility and Tender Stages 1090
XVIII.1.2. Alternative Route Selection during Design Stage 1093

XVIII.1.3. Alternative Route Selection after Design Stage 1095
XVIII.2. Motorway Design Parameters 1095
XVIII.3. No Project Alternative 1095
XIX. PUBLIC CONSULTATION 1097
XIX.1. INTRODUCTION 1097
XIX.1.2. Objectives 1098
XIX.2. Regulatory Requirements 1098
XIX.2.1. National Requirements 1098
XIX.2.2. International Requirements and Standards 1099
XIX.3. STAKEHOLDER ENGAGEMENT ACTIVITIES 1101
XIX.3.1. Stakeholder Engagement Methods 1101
XIX.3.2. Previous Stakeholder Engagement 1101
XIX.3.3. Stakeholder Engagement as part of the ESIA Process 1106
XIX.3.4. Road Trip 1107
XIX.3.5. Field Study with Women 1112
XIX.3.6. Public Consultation Meetings Summary 1112
XIX.3.7. Internal Stakeholder Engagement Activities 1134
XIX.4. STAKEHOLDER IDENTIFICATION 1134
XIX.4.1. Stakeholder Identification Methodology 1135
XIX.4.2. Stakeholder Categorization 1135
XIX.4.3. Field Study Report 1146
XIX.5. STAKEHOLDER ENGAGEMENT PLAN 1147
XIX.5.1. Methods and Tools for Information Dissemination and Stakeholder Engagement 1147
XIX.5.2. Specific Communication Strategies 1150
XIX.5.3. Operation Phase Community Engagement Plan (Post-Construction) 1153
XIX.5.4. Schedule and Timetable 1154
XIX.6. ROLES AND RESPONSIBILITIES 1154
XIX.7. GRIEVANCE MECHANISM 1155
XIX.7.1. Purpose of the Grievance Mechanism 1155
XIX.7.2. Responsible Stakeholders 1155
XIX.7.3. Grievance Mechanism at the National Level 1155
XIX.7.4. Community Grievance Mechanism at the Project Level 1156
XX. ENVIRONMENTAL AND SOCIAL MANAGEMENT SYSTEM 1214
XX.1. Environmental and Social Policy Framework 1214
XX.1.1. Environmental Policy 1215
XX.1.2. Integrated Management Systems Policy 1215
XX.1.3. Quality Policy 1216
XX.1.4. Occupational Health and Safety Policy 1217
XX.1.5. Sustainability Policy 1217
XX.1.6. Human Resources Policy 1218
XX.1.7. Data Privacy and Security Policy 1219

XX.1.8. Zero Tolerance Policy Against Violence and Violation Of Sexual Inviolability 1221
XX.2. Environmental and Social Management System Structure 1222
XX.3. Environmental and Social Management Plans (ESMPs) 1223
XX.4. Roles and Responsibility 1225
XX.5. Organization Capacity and Competency 1241
XX.5.1. Construction Phase 1242
XX.5.2. Operation Phase 1242
XX.6. Monitoring and Review 1243
XX.6.1. Internal Monitoring 1243
XX.6.2. External Monitoring 1244

LIST OF TABLES

Table I.1. Summary of the Key Project Information 37
Table I.2. Road Network of Türkiye as of January 2025* 5
Table II.1 National Environmental Legislation Applicable to the Project 15
Table II.2. Relevant Regional Board for Preservation of Cultural Assets 24
Table II.3. Relevant Museum Directorates 24
Table II.4 IFC's Performance Standards and their Applicability to the Project 30
Table II.5 Project Standards 37
Table II.6 Summary of Permits 44
Table III.1. Information of the Motorway 49
Table III.2. Motorway Design Criteria 50
Table III.3. Updated Design Criteria of the Project 51
Table III.4. Details on the Access Roads 52
Table III.5. Locations of the Borrow Pits/Quarries and Plants 56
Table III.6. List of Storage Sites Planned to be used 66
Table III.7. Summary of the Engineering Structures for the Project 67
Table III.8. Viaducts to be Constructed for the Motorway 68
Table III.9. Bridges to be Constructed for the Motorway 68
Table III.10. Overpass to be Constructed for the Motorway 69
Table III.11. Underpasses to be Constructed for the Motorway 71
Table III.12. Culverts to be Constructed for the Motorway 73
Table III.13. Interchanges to be Constructed for the Motorway 74
Table III.14. Tunnels to be Constructed for the Motorway 75
Table III.15. Transportation Routes Between Material Supply Points and Construction Sites 76
Table III.16. List of Service Areas 90
Table III.17. Pavement Layers and their Thickness 91
Table III.18. Brief description of the Motorway 93
Table III.19. Settlements Located in The Vicinity of the Motorway Components 94
Table III.20. Workforce Distribution by Project Phase and Employment Type 96
Table III.21. List of Construction Machinery 97
Table III.22. Road Assessment for Transportation of Heavy Loads 101
Table IV.1. Interaction Potential Matrix for Scoping 109
Table IV.2. Proposed Study Area for the Motorway 111
Table IV.3. Summary of the Studies and Measurements Planned/Conducted within the Scope of ESIA Studies 112
Table IV.4. Impact Categorization Matrix* 115
Table IV.5. Typical Descriptors to be considered in Assigning Individual Value/Sensitivity Criteria 116
Table IV.6. Impacts Magnitude Criteria 117
Table V.1. Criteria for Sensitivity/Value of Resource/Receptor 120
Table V.2. General Land Cover Classification of the CORINE Database 121
Table V.3. Land Use Characteristics along the Project Route according to CORINE 2018 125

Table V.4. Land Use Characteristics along the Project Route according to STATİP 2015 132
Table V.5. Agricultural Potentials Represented by Different Land Use Capability Classes and Their Characteristics 139
Table V.6. Usage Suitability Matrix for Different Land Use Classes 140
Table V.7. Land Use Characteristics and Capabilities within the Study Corridor (according to Turkish General Directorate for Rural Services, 1993) 141
Table V.8. Comparison of Areas for Different Land Use Types According to CORINE (2018), STATIP (2015) GDRS (1993) Databases 153
Table V.9. Functions of Forests and Associated Management Goals 154
Table V.10. Relevant Forestry Directorates for the Project 156
Table V.11. Canopy Cover Classification According to Forest Management Plans 156
Table V.12. Distribution of Forestlands according to their Functions and Types within the Study Area 158
Table V.13. Land Use Properties and Forestlands according to Stand Types within the Expropriation Corridor 159
Table V.14. Land Use Capabilities of the Agricultural Areas within the Study Corridor (according to Turkish General Directorate for Rural Services, 1993) 160
Table V.15. Land Use Capability of Agricultural Lands in Each Settlement (GDRS, 1993) 161
Table V.16. Distribution of Lands According to Type of Ownership and Number of Corresponding Parcels within the Expropriation Corridor 163
Table V.17. Areas and Land Use Information for the Construction Compounds 165
Table V.18. Forest Areas to be Acquired in the Scope of the Project 169
Table V.19. Areas and Land Use Information for the Construction Compounds 169
Table V.20. Estimated Number of Trees to be Removed in the Motorway 171
Table V.21. Trees to be Removed According to their Types 172
Table V.22.Pasturelands to be Affected by the Project 173
Table V.23.Area to be Affected by Quarry/Material Borrow Site Operations 175
Table V.24.Area to be Affected by Excavated Material Storage Sites 176
Table V.25.Summary of the Land Use Assessments 184
Table VI.1. Criteria for Sensitivity/Value of Resource/Receptor 188
Table VI.2. Slope Groups within the Study Corridor of the Project 189
Table VI.3. Description of Soil Groups 195
Table VI.4. Soil Groups within the Study Corridor of the Project (GDRS. 1993) 195
Table VI.5. Erosion Levels according to Technical Procedure on Soil and Land Classification Standards 202
Table VI.6. Erosion Potential of the Soils within the Study Corridor of the Project (GDRS. 1993) 203
Table VI.7. Erosion Levels of Soils in the Settlements within the Study Corridor (GDRS. 1993) 203
Table VI.8. Typical Composition of Topsoil 211
Table VI.9. List of Soil Sampling Locations (September, 2024) 212
Table VI.10 List of Soil Sampling Locations (May,2025) 212
Table VI.11 Soil Measurement Results (September, 2024) 216
Table VI.12 Soil Measurements in Quarry Areas (May,2025) 218

Table VI.13 Soil Measurements in Camp Site Areas, Temporary Storage Areas (May,2025) 220
Table VI.14 Soil Measurements in Storage Areas-1 (May,2025) 222
Table VI.15 Soil Measurements in Storage Areas-2 (May,2025) 223
Table VI.16 Soil Measurements in Other Locations 224
Table VI.17 List of Boreholes Drilled at Serik Junction and Connection Roads 240
Table VI.18 List of Boreholes drilled on Antalya State Road 241
Table VI.19 List of Boreholes Drilled on the Project Route 242
Table VI.20. M ≥ 4 Earthquakes in the Region 265
Table VI.21 Excavation and Fill Volumes for the Motorway 270
Table VI.22 Local Soil Classes (Principles for the Design of Highway and Railway Bridges and Viaducts Under Earthquake Effects, 2020) 276
Table VI.23 Local Soil Impact Coefficients for Short Period Region (TBDY, 2018) 277
Table VI.24. Summary of the Topography, Soils and Geology Assessments 284
Table VII.1. Criteria for Sensitivity/Value of Resource/Receptor 289
Table VII.2. Types of Mining Groups and their Description 291
Table VII.3. Raw Material Extraction Sites to be used in the Project 291
Table VII.4. Landfills and Transfer Stations in Antalya Province 292
Table VII.5. Locations of the Quarries, Plants and Storage Sites 295
Table VII.6. Indicative List of the Potentially Generated Wastes Types During the Land Preparation and Construction Activities 297
Table VII.7. Estimated Solid Municipal Waste Generation of the Campsites 300
Table VII.8. Estimated Municipal Wastewater Generation and Water Usage of the Campsites 302
Table VII.9 Water Consumption in Concrete Plants and Mechanical Plant Manufacturing m^3 303
Table VII.10. Estimated Engine Oil Waste Amounts 305
Table VII.11. Wastes to be collected by the Contractor 312
Table VII.12. Summary of the Assessments Waste Management 314
Table VIII.1. Information on Dam Lakes in the Basin 320
Table VIII.2 Pressures and Impacts on Rivers/Streams on the Route 323
Table VIII.3 Groundwater Quality Sampling Stations 333
Table VIII.4 Surface Water Quality Sampling Stations 333
Table VIII.5 Results of Water Quality Analysis Based on Annex-5 Table 2 of Surface Water Quality Regulation 337
Table VIII.6 Results of Water Quality Analysis Based on Annex-5 Table 2 of Surface Water Quality Regulation (continued) 338
Table VIII.7 Water Quality Classes of the Sampled Water Resources 339
Table VIII.8 Results of Water Quality Analyses with respect to Primary Substances given in Annex-5, Table 5 of Surface Water Quality Regulation 341
Table VIII.9 Results of Water Quality Analyses with respect to Primary Substances given in Annex-5, Table 5 of Surface Water Quality Regulation (continued) 342
Table VIII.10 Results Groundwater Quality Analysis Based on Annex-5 Table 2 of Surface Water Quality Regulation 345
Table VIII.11 Assessment of Groundwater Sampling Locations Against Project Standards 346

Table VIII.12 Amount of Wastewater to be produced in the Construction Phase 358
Table VIII.13 Domestic Wastewater Discharge Requirements 359
Table VIII.14 Summary of the Assessments on Water Resources 367
Table IX.1. Biodiversity Field Study Team Members 370
Table IX.2. International Union for Conservation of Nature (IUCN) Categories 372
Table IX.3. National Threat Categories for Bird Species 374
Table IX.4. Observation and Sampling Points of Antalya-Alanya Motorway Project Route 388
Table IX.5. Observation Points for Bat Surveys 390
Table IX.6 Storage Areas 391
Table IX.7. Locations of the Borrow Pits/Quarries and Plants 391
Table IX.8. Internationally Recognized Areas within the Region of the Project Area 393
Table IX.9 Nationally Recognized Areas within the Region of the Project Area 393
Table IX.10. Distances of Internationally Recognized Areas from the Project Area 393
Table IX.11. Criteria for Sensitivity/Value of Resource/Receptor 404
Table IX.12. EUNIS Habitat Types and Their Respective Areas within the Project Study Area 408
Table IX.13 Relative Abundance and Presence for Terrestrial Flora Species 420
Table IX.14 Observation Method and Observed Stations for Amphibians 422
Table IX.15 Scientific Name, Observation Method, and Observed Stations 423
Table IX.16 Relative Abundance and Presence of Species for Reptile and Amphibian Species 424
Table IX.17 Scientific Name and Type of Detection for Birds 426
Table IX.18 Relative Abundance and Presence of Species for Birds 431
Table IX.19 Observation Method, and Species Presence in Sampling Points for Mammals 434
Table IX.20 Relative Abundance and Presence of Species for Mammals (Bats) 435
Table IX.21 Species Observation Stations and Type of Detection for Fishes 440
Table IX.22 Relative Abundance and Presence of Species for Fishes 441
Table IX.23 Critical Habitat Assessment According to Criterion-1 444
Table IX.24 Critical Habitat Assessment According to Criterion-2 445
Table IX.25 Critical Habitat Assessment According to Criterion-3 446
Table IX.26. Critical Habitat Assessment Results 448
Table IX.27. Priority habitats and species of conservation importance 451

I. INTRODUCTION

Ministry of Transport, and Infrastructure (former Ministry of Transport, Maritime Affairs and Communications), General Directorate of Highways ("KGM" or "the Administration"), as the owner of the Antalya-Alanya Motorway Project, has tendered for a contract in accordance with the Law on Implementation of Some of the Investments and Services in the Framework of Build, Operate and Transfer Model (Law No: 3996). Following the tendering process, KGM has awarded Antalya-Alanya Otoyolu İnşaat Yatırım ve İşletme A.Ş. (AAOİAŞ or the Project Sponsor) with a Build, Operate and Transfer (BOT) contract for the implementation of the Project. Accordingly, AAOİAŞ will be referred as Project Sponsor[1] in the scope of this report. The main contractor for the Project has been designated as Limak and will henceforth be referred to as the Contractor (or EPC).

This report has been prepared by ENCON Environmental Consultancy Co. (ESIA Consultant or "ENCON") to document the Environmental and Social Impact Assessment (ESIA) studies conducted for the Antalya-Alanya Motorway Project ("the Project").

The Project is one of the two sub-projects that constitute the Afyonkarahisar-Alanya Motorway Project, and is designed to connect Serik and Alanya districts through Manavgat district of Antalya province. The Project will enhance the existing transportation network services with its surrounding provinces: Burdur, Muğla, Konya, Isparta, Karaman and Mersin. Various environmental, social, and technical studies have been conducted along the initial route of the Project tendered by the KGM. Based on these studies, the route was optimized, incorporating engineering practices and addressing environmental and social considerations, particularly issues of involuntary and economic resettlement, before being finalized. According to the most current design, the total length of the Motorway, which will be a dual carriageway of mostly 3 and partially 2 lanes (3x2 and 2x2) in each direction, is 117.8 kilometers including the main carriageway and the access roads[2].

Summary of the key information of the Project is provided in Table I.1 while Figure I.1 presents a map illustrating the entire route.

Table I.1. Summary of the Key Project Information

Contractor	Major Components	Specifications
AAOİAŞ	Main Motorway (Serik Interchange to Alanya Junction)	84 km of 3 line dual carriageway
	Access Roads (Serik, Taşağıl, Manavgat, Manavgat East, Alarahan, Konaklı, Alanya West)	33.8 km of 2 line dual carriageway

The component distances are approximates according to the current design.

[1] *The BOT Contract uses the term "Appointed Company" to refer Project Sponsor.*
[2] *It should be noted that the environmental and social baseline characterization, maps and scoping assessments provided in this report are based on the most current design*

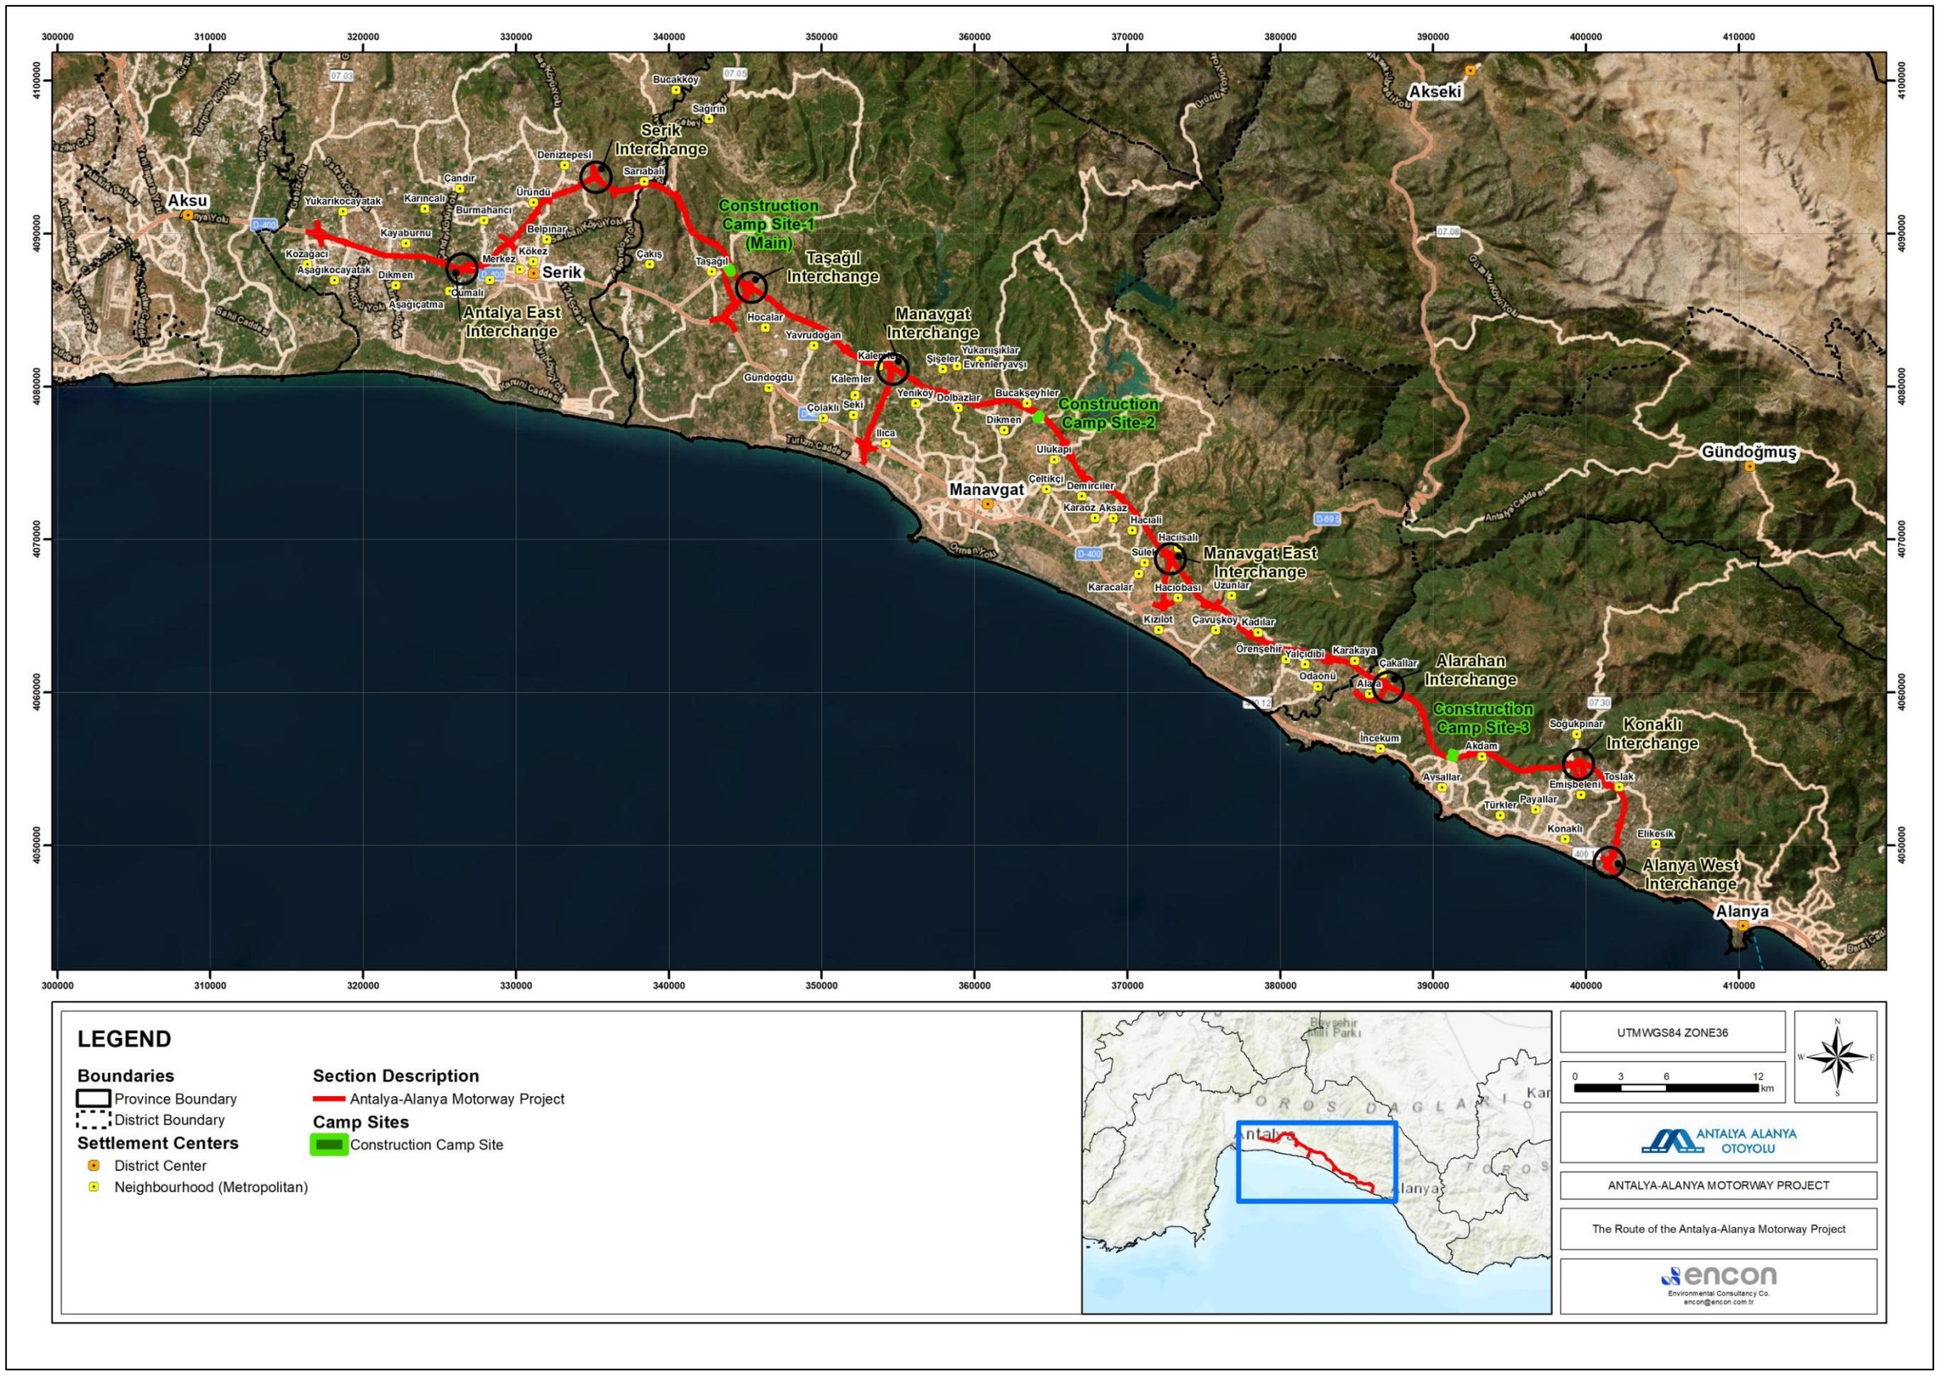

Figure I.1. The Route of the Antalya-Alanya Motorway Project

I.1. Aim of the ESIA Report

Expenditure on new development of roads is likely to be a major component of national budgeting. Due to high cost of construction and budget constraints, financing new motorway projects by national budget is difficult. Thus, in the recent years, build-transfer-operate (BOT) models, based on the project experience of the private sector and support of financial institutions, has been one of the most effective mechanisms in Türkiye for realizing large-scale motorway projects without causing burden to state budget (*KGM, June 2011*).

The Antalya-Alanya Motorway is a project that has been tendered out in the framework of BOT model. As the winning bidder, Project Sponsor seeks finance from financial institutions/potential lenders, who would require international environmental and social standards and guidelines to be adopted in the implementation of the Project. In consideration of Equator Principles, World Bank Environmental and Social Framework (ESF) and International Finance Corporation's (IFC) Sustainability Framework, the Project is evaluated to include activities and components that need to be effectively managed to avoid or minimize significant environmental and social impacts. In this respect, a detailed description of the national and international legal framework for the Project is provided in Chapter II of this report. Based on a detailed review and evaluation of a number of screening criteria defined in European Union's (EU) Environmental Impact Assessment (EIA) Directive, Turkish EIA Regulation as well as World Bank, IFC policies and guidelines, and Equator Principles 4 guidelines, the Project, with its specifically identified physical elements, aspects and facilities that are likely to generate potentially significant adverse environmental and social risks and impacts, has been proposed as a "Category A" project. For "Category A" projects, a comprehensive full-scale ESIA is required to be conducted (see Chapter II).

In line with the Category A designation, the Project Sponsor is responsible for preparing an Environmental Impact Assessment (EIA) Report as per national legislations, and a full-scale ESIA as per international finance organizations' requirements. The EU's EIA Directive and the Turkish EIA Regulation, which has been harmonized with EU's EIA Directive also define the motorway construction projects as Annex I activities, for which an EIA is required ("EIA Positive Decision" taken for the Project on August 17, 2018 and has validity until August 17, 2025). To secure financing for the Project, the environmental and social standards required by the potential international lenders must be met. Accordingly, the full-scale ESIA process was initiated for the Project officially in May 2024.

According to internationally accepted and applied impact assessment procedures, an ESIA process starts with the initial screening of the project and scoping of the assessment, and followed by other key process elements including examination of alternatives; stakeholder identification (focusing on those directly affected); gathering of environmental and social baseline data; impact identification, prediction, and analysis; generation of mitigation or management measures and actions; evaluation of significance of impacts and residual impacts; and documentation of the assessment process, which all together form an ESIA report (*IFC, January 2012*). The findings of the screening and scoping studies were documented in the Scoping Report and Inception Report of the Project, both dated July 2024. The primary aim of the Scoping Report has been the identification of the environmental and social issues and impacts that are anticipated to be significant, as well as to outline the scope of the ESIA Report. The Inception Report focused on detailing the methodologies to be applied throughout the ESIA process further refining the ESIA contents previously defined in the Scoping Report, and documenting the conducted field studies.

Following the scoping phase, other key processes including examination of alternatives; stakeholder identification (focusing on those directly affected) and engagement; gathering of environmental and social baseline data by means of desk-based and field studies[3]; impact identification, prediction, and analysis; generation of mitigation or management measures and actions; evaluation of significance of impacts and residual impacts; and documentation of the assessment process, were conducted in accordance with the requirements of the relevant Turkish laws and regulations, Equator Principles and IFC's Performance Standards and Sustainability Framework. The findings of the entire process have been compiled in this ESIA Report, prepared for the Antalya-Alanya Motorway Project.

This report has been structured as follows:

- Chapter I : Introduction
- Chapter II : Institutional and Legal Framework
- Chapter III : Project Description
- Chapter IV : ESIA Methodology
- Chapter V : Land Use and Property
- Chapter VI : Topography, Soils and Geology
- Chapter VII : Use of Resources and Wastes
- Chapter VIII : Water Resources
- Chapter IX : Ecology and Biodiversity
- Chapter X : Air Quality and Climate Change
- Chapter XI : Noise and Vibration
- Chapter XII : Protected Areas, Landscape and Visual Environment
- Chapter XIII : Archaeological and Immovable Cultural Heritage
- Chapter XIV : Socio-economic Environment
- Chapter XV : Community Health and Safety
- Chapter XVI : Labor and Working Conditions
- Chapter XVII : Cumulative Impact Assessment
- Chapter XVIII : Analysis of Alternatives
- Chapter XIX : Public Consultation
- Chapter XX : Environmental and Social Management System
- Annexes

The assessments done in the scope of this ESIA Report are based on the most current design and the information given in Chapter 3 ("Project Description").

I.2. Need for and Aim of the Project

Current Overview of the Motorways of Türkiye

The demand for freight and passenger transportation in Türkiye has two sources based on internal and external dynamics. The demand created by internal dynamics varies entirely depending on the current income level of Türkiye. As income increases, mobility also increases, triggering the transportation sector. Secondly, the demand created by external dynamics arises from transit transportation through Türkiye. In 2022, domestic freight transport was predominantly by road,

[3] *Site surveys have been conducted for all relevant environmental and social subjects (i.e. water, soil, air, noise, flora and fauna, and social) to collect/gather up-to-date/valid baseline information characterizing the existing conditions.*

accounting for 89.3%, while railways contributed 4.6% and maritime transport 6.1%. Passenger transport rates for 2022 were similarly dominated by road at 91.2%, followed by air at 6.8%, railways at 1.5%, and sea at 0.48%[4].The road network under the responsibility of KGM is as of January 1, 2025 is given in Table I.2, and motorway network of Türkiye as of 2023 is presented in Figure I.2.

Table I.2. Road Network of Türkiye as of January 2025*

Road Type	Road Length (km)	Length of Dual Carriageway (km)
Motorways**	3,796	3,796
State Roads	30,825	21,858
Provincial Roads	33,996	2,414
Total	68,617	28,068

** Source: KGM, 2025[5]*
*** BOT contracted motorways are included.*

The Project is situated within the administrative jurisdiction of the 13th Regional Directorate of the General Directorate of Highways (KGM). Encompassing an area of 44,119 km^2, the jurisdiction spans the entirety of Antalya, Isparta, and Burdur provinces, as well as parts of Afyon and Muğla provinces. Ninety-six percent (69%) of the road network managed by the 13th Regional Directorate consists of asphalt-paved roads, totaling 3,341 km in length. The region under the purview of the 13th Regional Directorate is home to a total population of 3,836,236 individuals, with 2,517,970 registered vehicles utilizing the roadways.

Economic and Social Significance of the Project

Effective transportation infrastructure is a key to the development of countries. Today, transportation has become one of the basic needs of the mankind and a prominent driving force for the socio-economic development. In this respect, road transportation provides the most flexible transportation means as far as the topography, amount of the load to be transported and the time is concerned. Road transportation is usually preferred as it enables non-stop and fast transportation and thus most of the time is the most economical alternative when compared to other transportation systems.

Playing a key role in economic development and enhancement of welfare, road transportation is not only an important economic activity on its own but it also paves ground for interaction between different sectors. The fact that time gains primary importance in the globalizing world raises the importance of road transportation as it provides the ability to compete and establish flexible relations (*KGM, August 2010*).

States prioritize motorway investments for several compelling reasons. Firstly, efficient transportation infrastructure serves as the foundation of economic activity. Motorways facilitate the movement of goods and people, connecting businesses to markets, workers to jobs, and tourists to destinations. This interconnectedness fosters economic growth by stimulating trade and investment. Secondly, modern motorways prioritize safety by incorporating features like wider lanes, guardrails, and median barriers. These design elements significantly reduce traffic accidents, fatalities, and injuries, leading to a safer transportation network. Thirdly, investments in expanding motorways or improving traffic flow management systems can alleviate traffic congestion. This not only conserves time for commuters but also reduces fuel consumption and emissions from idling vehicles, contributing to environmental sustainability. Furthermore, well-maintained motorways bridge the gap between rural and urban areas by providing essential services, education, and healthcare access for residents in remote locations. This improved accessibility enhances the overall quality of life for people across the state. Finally, efficient motorways are critical for emergency response vehicles, ensuring faster response times for ambulances and fire trucks in times of crisis.

Akdeniz Region of Türkiye has a particular role in the tourism and agriculture sectors. The Project is planned in the Akdeniz Region, aiming to strengthen the region's capacity to serve this role in the most efficient and effective way possible. The Project is a vital component of a broader motorway network projects that aim to strengthen the existing road infrastructure and improve the accessibility and coverage throughout the region. The geographical positioning, rich cultural heritage, and historical landmarks, coupled with its favorable climate, render the Akdeniz Region a paramount center for both tourism and accommodation, and agriculture within Türkiye. The Project is an important opportunity to increase accessibility to the facilities located between Antalya province and Alanya district, which encompasses the accommodation facilities that cater to 9,093,324 visitors annually, 96.08% of whom are foreigners, according to 2021 data of the Turkish Statistical Institute (TurkStat)[7]. The Motorway route lies on the east-west axis on the southern coast of Türkiye, holding substantial significance in linking these prominent tourism centers.

Simultaneously, the region serves as a focal point for the cultivation of numerous fruits, notably citrus varieties, alongside year-round production of vegetables and flowers by greenhouses. The Project is anticipated to assume a crucial role in enhancing the efficiency of transporting these high-value agricultural commodities rapidly to both domestic and international markets, ensuring their faster delivery and hence increasing product freshness and quality.

Motorway investments play an important role in the infrastructure development strategies of nations. This role is especially important in Türkiye's transportation sector, where 91% of passenger

[7] *Source: https://biruni.tuik.gov.tr/ilgosterge/?locale=tr*

transportation and 89% of freight transportation rely on road networks[8]. Motorways offer efficient, safe, and rapid travel services, essential for overcoming the topographic and geological challenges present in Türkiye's terrain. Despite their strategic importance, motorway investments entail significant expenses in both initial capital outlay and ongoing operational costs. Given Türkiye's geographical position bridging historic and present-day economic and cultural trade routes, ensuring the security, comfort, and efficiency of these corridors is paramount to fostering new opportunities for economic and political collaboration. Consequently, Türkiye is improving its infrastructure by identifying crucial road corridors in order to achieve the targeted socio-economic goals and to realize the projects determined to be feasible through careful cost-benefit analyses.

Furthermore, each year, over 4,000 lives are tragically lost in traffic accidents on Türkiye's roads, resulting in an annual economic loss of approximately 5 billion dollars, with an additional 180,000 individuals suffering permanent disabilities[9][10]. In light of these disquieting statistics, the necessity for new motorway projects featuring dual carriageways and meeting stringent technical safety standards, aimed at improving the safety of passenger and freight transportation has become evident.

The Project's primary aim is to relieve the intense traffic burden on the Akdeniz Region's existing road network while building the capacity needed to accommodate future traffic. This purpose is aimed to be achieved by separating local traffic driven by urbanization and industrialization from intercity and international traffic. The Project, subject to this ESIA study, will create a transit corridor for freight that bypasses congested city centers.

In addition to improving transportation networks and benefiting users, the Project is expected to generate social and economic advantages, including job creation, local and regional development, better access to employment, markets, education, healthcare, and cultural/tourism facilities, as well as improved emergency response times and contributions to the national budget through tax revenues and strengthened national security. However, to maximize these benefits and ensure the Project's environmental and social acceptance, it is essential to effectively manage its potential impacts as outlined in this ESIA Report. As a result of these efforts, the quality of transportation services will improve, and the Project will help reduce traffic-induced energy consumption, air emissions, and time losses.

I.3. Background to the Project

The implementation of the Project (for which an EIA positive decision was taken in 2018), was tendered out in the framework of BOT model. Following the signing of the BOT contract, Project Sponsor has continued route, optimization and design works in cooperation with KGM and other related state authorities. The design of the Project has progressed and will progress in parallel to the ESIA studies. It should be noted that in case of any design change during and after the ESIA study has been completed, the Project would be managed in the scope of ESMS by means of Change Management Procedure and Project Sponsor will inform the relevant Ministry and fulfill the relative legislative requirements.

The Project starts at Serik Interchange (Km: 52+000) and then proceeds eastward, following the corridor at the foothills of the Taurus Mountains within the boundaries of Serik and Manavgat districts, ending at north of Konaklı neighborhood of Alanya District (Km: 136+000). From this point onwards, the route turns southward with a 2x2 lane connection road and connects to the D400 state road at the Alanya West Interchange. As of April 2025, the current Project design includes a total of 117.8

[8] *https://cevreselgostergeler.csb.gov.tr/ulastirma-turlerine-gore-tasinan-yolcu-ve-yuk-miktari-i-85789*
[9] *https://dergipark.org.tr/tr/download/article-file/2119555*
[10] *https://data.tuik.gov.tr/Bulten/Index?p=Karayolu-Trafik-Kaza-Istatistikleri-2023-53479*

kilometers of road, comprising 84 kilometers of main road (motorway) and 33.8 kilometers of access roads. The Motorway will be a dual carriageway with three lanes (3x2) along the 84 kilometers stretch, and the access roads will have two lanes (2x2) over the 33.8 kilometers length.

The expropriation plans for the current route have been submitted to KGM, and the land use permit processes have been continued by the Project Sponsor. On the other hand, based on the information provided by the Project Sponsor, permits for construction activities will be obtained gradually as the Project advances. Once the permitting activities reach a significant milestone, the status of the permits will be included in the Environmental and Social Action Plan (ESAP) Report.

It should be noted that the studies and assessments provided in this report are based on the current design. More information on the Project description is provided in Chapter III.

II. INSTITUTIONAL AND LEGAL FRAMEWORK

This chapter describes the institutional framework in Türkiye and identifies the national environmental legislation, international agreements and protocols and international environmental and social standards including Equator Principles IV and International Finance Corporation's (IFC) Policy (2012) and related Performance Standards (PSs) on Environmental and Social Sustainability that would be applicable to the Project.

II.1. Institutional Framework

Administrative structure in Türkiye is governed by central and local administrations. The central administration is organized so that the land mass of the country is divided into provinces and the provinces into further smaller divisions (i.e. districts, municipalities, villages/neighborhoods) according to geographic and economic conditions, and the need for public services. For the purpose of meeting collective local needs, the populations of provinces, municipalities, and villages/neighborhoods are administered by units of local government established by law (*Toksoz, F., 2006*). A general depiction of the institutional framework in Türkiye with relevance to the Project is shown in Figure II.1.

Ministries are the units of central administration. Local branches of ministries are composed of provincial organizations attached to governors and district organizations attached to the district governors (*Hacettepe University, Department of Political Science and Public Administration, April, 2015*). At the local level, municipality mayors and the mukhtars of the villages/neighborhoods are the representatives of the administrative structure.

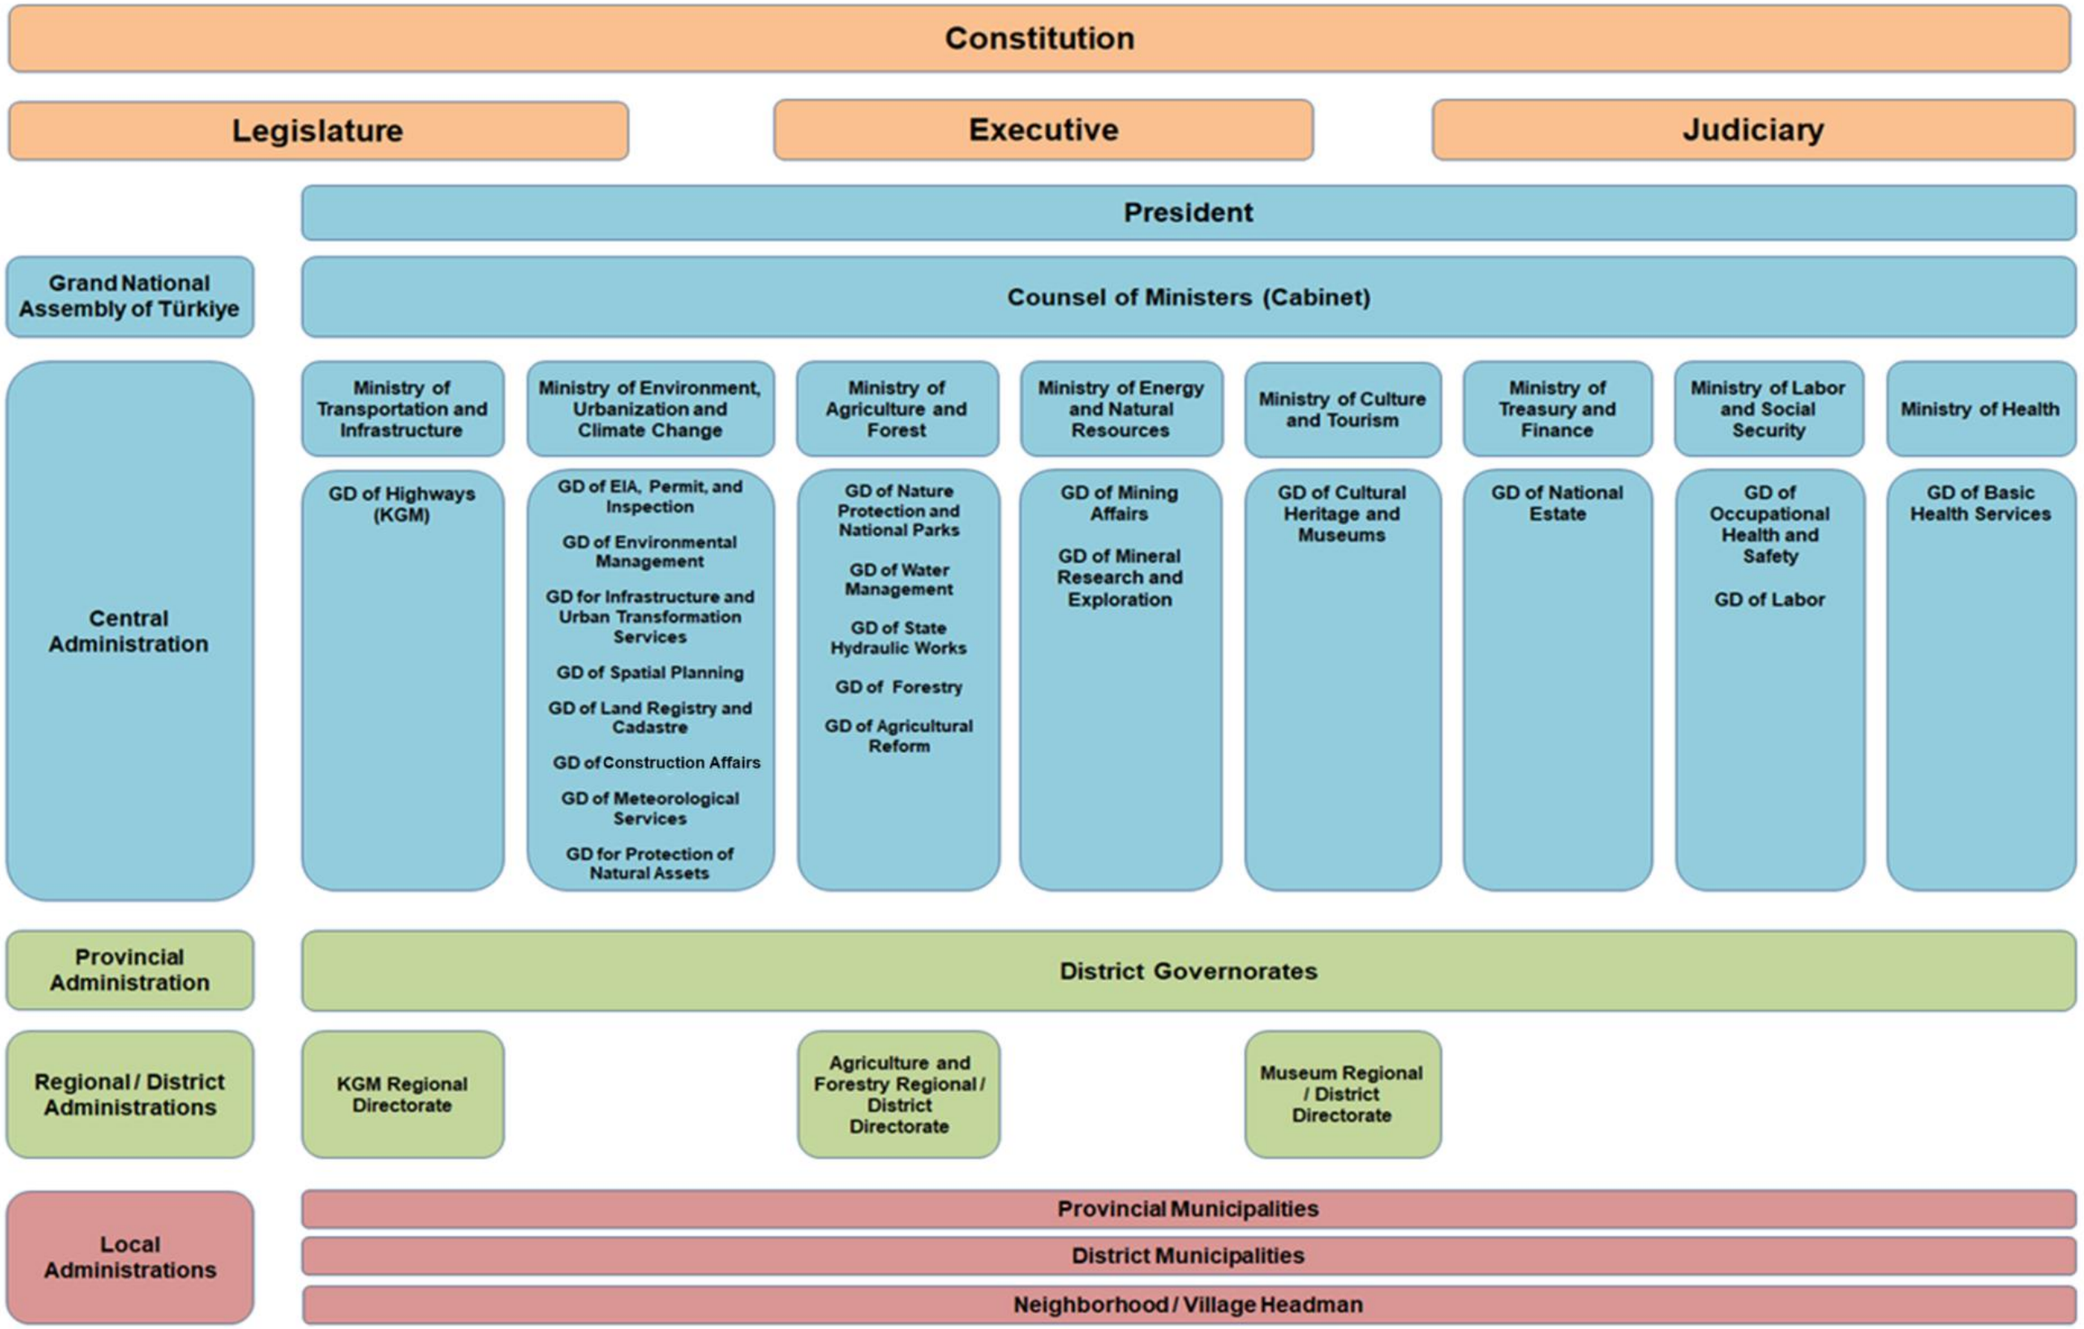

Figure II.1 Institutional Framework in Türkiye related to the Project

II.1.1. Central Administrations

Central administration is the core of the administrative structure. Each Ministry, being a unit of central administration, is headquartered in Ankara, with units at the provinces serving as their field organizations (*Toksoz, F., 2006*).

Ministry of Transport and Infrastructure (MoTI) is the key central administration in the scope of the Project. Under the Ministry, General Directorate of Highways is the authority responsible from the implementation of the Project.

In Türkiye, the Ministry of Environment, Urbanization and Climate Change (MoEUCC) is the responsible organization for the implementation of policies adopted for the protection and conservation of the environment, sustainable development and management of natural resources and national strategies for minimizing climate change effects. Thus, the MoEUCC will be the authority with the MoTI (through the General Directorate (GD) of KGM) and the Project Sponsor will collaborate regarding the assessment and management of environmental aspects of the Project.

The Ministry of Environment was first established as an Under-secretariat of the Prime Minister's office in 1987 and was promoted to the rank of Ministry of Environment in August 1991 by the Establishment Law No. 443. Then, the Ministry of Environment and Forestry was established in 2003 through a merger of the previously separate Ministry of Environment and the Ministry of Forestry. Recently, the environment part of the former Ministry of Environment and Forestry was separated and merged with the Ministry of Public Works and Settlement to form the Ministry of Environment and Urbanization. Finally, with a Presidential decree, the determination of climate change strategies was added to its duties in order to address the effects of climate change, and its name changed to The Ministry of Environment, Urbanization and Climate Change (MoEUCC).

The MoEUCC has an overall coordinating role for the development and implementation of environmental policies in Türkiye, including the approximation process for the EU Environmental Acquis. The MoEUCC is composed of the 16 different general directorates. The general directorates, which are relevant to or may have an interest in the Project, are listed below:

- Ministry of Environment, Urbanization and Climate Change
  - Directorate General of Environmental Management
  - Directorate General of Environmental Impact Assessment (EIA), Permit, and Inspection
  - Directorate General of Spatial Planning
  - Directorate General of Land Registry and Cadastre
  - Directorate General of Meteorological Services
  - General Directorate for Protection of Natural Assets
  - Directorate General of Construction Works

The MoEUCC holds the following principal responsibilities within Türkiye's environmental governance framework:

- Draft and enact legislation concerning environmental management, public infrastructure, and housing development, and ensure its effective enforcement through routine monitoring and auditing.
- Establish national strategies and guiding principles for environmental conservation, pollution control, and ecological restoration; develop and enforce related standards,

criteria, and implementation programs; and lead initiatives related to climate change adaptation and mitigation.

- Review and regulate facilities and activities with potential environmental impacts arising from the discharge of pollutants in solid, liquid, or gaseous form into natural receiving environments; conduct environmental permitting and compliance monitoring.
- Execute environmental measurement, monitoring, and analytical activities related to receiving environments.
- Formulate national frameworks and policy instruments addressing climate change and oversee the implementation of related preventive and adaptive measures.

For the management of environmental issues, MoEUCC collaborates with other ministries, government agencies and relevant stakeholders. Ministries (through related General Directorates), which would be relevant to or may have an interest in the Project, are listed below:

- Ministry of Transport and Infrastructure (MoTI)
  - General Directorate of Highways (KGM)
- Ministry of Agriculture and Forestry
  - General Directorate of Nature Protection and National Parks
  - General Directorate of Water Management
  - General Directorate of State Hydraulic Works
  - General Directorate of Forestry
  - General Directorate of Agricultural Reform
- Ministry of Culture and Tourism
  - General Directorate of Cultural Heritage and Museums
- Ministry of Energy and Natural Resources
  - General Directorate of Mining and Petroleum Affairs
  - General Directorate of Mineral Research and Exploration
- Ministry of Environment, Urbanization and Climate Change
  - General Directorate of National Estate
- Ministry of Labor and Social Security
  - General Directorate of Occupational Health and Safety
  - General Directorate of Labor
- Ministry of Health
  - General Directorate of Health Services

II.1.2. Provincial, Regional and District Level Administrations

Provincial, regional and district level administrations are the field organizations of the Ministries. Under the MoTI, GD of KGM, Antalya 132nd and Alanya 133rd Branch Directorates are the related local authorities. Antalya province also falls in the jurisdiction of the 13th Regional Directorate of KGM.

The MoEUCC, Ministry of Agriculture and Forestry, Ministry of Culture and Tourism and Ministry of Health have provincial directorates in Antalya province under the related Governorate. Provincial

directorates under the Antalya Governorate are the local governmental authorities related with the Project.

In addition, the Project is located within the jurisdiction of the 6th Regional Directorate of the Ministry of Agriculture and Forest located in Antalya province. The Project falls under the jurisdiction area of the 13th State Hydraulic Works (DSI) under the same Ministry.

Regarding the cultural heritage, Antalya Regional Board for Preservation of Cultural Assets and Antalya Protection Council under the Antalya Cultural Heritage Preservation Regional Board Directorate will be the responsible authority along the Project route.

II.1.3. Local Administrations

Local administration, which functions under the administrative tutelage of the central administration, is divided into three main administrative tiers. These are the special provincial administrations, municipalities, and village/neighborhood administrations (*Toksoz, F., 2006*). Since Antalya is a metropolitan municipality, no special provincial administration is present. Antalya Metropolitan Municipality, related district municipalities and the neighborhood mukhtar are the local administrations relevant to the Project.

II.2. Applicable Turkish Environmental and Social Legislation

Turkish Environmental Law (Law No: 2872), which came into force in 1983, handles environmental issues on a very broad scope. Under the Environmental Law, environmental regulations have been developed in line with national and international initiative and standards, and some of them have been revised recently to be harmonized with the European Union (EU) Directives in the scope of pre-accession efforts of Türkiye.

Complementary to the Environmental Law and its regulations, the laws listed below also govern the protection and conservation of the environment, prevention and control of pollution, implementation of measures for the prevention of pollution, health and safety and labor issues:

- Cadaster Law (Law No. 3402) (Official Gazette (OG): 09.07.1987 No. 19512)
- Code of Civil Law (Law No. 4721) (OG: 08.12.2001 No. 24607)
- Electricity Market Law (Law No. 6446) ((OG): 30.03.2013 – No. 28603)
- Energy Efficiency Law (Law No. 5627) (OG: 02.05.2007 – No. 26510)
- Expropriation Law (Law No. 2942) (OG: 08.11.1983 – No. 18215) (Law No. 2942, some articles of which were rearranged by Law No. 4650)
- Forestry Law (Law No. 6831) (OG: 08.09.1956 – No. 9402)
- Groundwater Law (Law No. 167) (OG: 23.12.1960 – No. 10688)
- Labor Law (Law No. 4857) (OG: 10.06.2003 – No. 25134)
- Law on the Conservation of Cultural and Natural Assets (Law No. 2863) (OG: 23.07.1983 – No. 18113)
- Law on Improvement of Olive Cultivation and Budding of Wild Species (Law No. 3573) (OG: 07.02.1939 – No. 4126)
- Law on Soil Protection and Land Use (Law No. 5403) (OG: 19.07.2005 – No. 25880)
- Mining Law (Law No. 3213) (OG: 15.06.1985 – No. 18785)
- Municipality Law (Law No. 5393) (OG: 13.07.2005 – No. 25874)

- National Parks Law (Law No. 2873) (OG: 11.08.1983 – No. 18132)
- Pasture Law (Law No. 4342) (OG: 28.02.1998 – No. 23272)
- Public Hygiene Law (Law No. 1593) (OG: 06.05.1930 – No. 1489)
- Public Finance Management and Control Law (Law No. 5018) (OG: 24.12.2003 No. 25326)
- Highway Traffic Law (Law No. 2918) (OG: 18.10.1983 – No. 18195)

The primary environmental laws, regulations, by-laws and communiques and other complementary regulations applicable to the infrastructure projects are listed below in Table II.1. Project Sponsor will comply with the requirements of relevant national legislations and codes of practice, and fulfill all other legal requirements.

Table II.1. National Environmental Legislation Applicable to the Project

Subject	Name of the Legislation
Land Use and Soils	
Agricultural lands	Law on Soil Protection and Land Use (Law No. 5403) (OG: 19.07.2005 – No. 25880)
	Implementation Regulation on Soil Protection and Land Use (OG: 09.12.2017 – No. 30265)
	By-law on Protection and Use of Agricultural Lands and Land Consolidation (OG: 09.12.2017 – No. 30265)
	Law on Improvement of Olive Cultivation and Budding of Wild Species (Law No. 3573) (OG: 07.02.1939 – No. 4126)
Forest lands	Forestry Law (Law No. 6831) (OG: 08.09.1956 – No. 9402)
	Implementation Regulation of Article 16 of the Forestry Law (OG: 24.09.2024 – No. 32672)
Pasture lands	Pasture Law (Law No. 4342) (OG: 28.02.1998 – No. 23272)
	Pastures Regulation (OG: 31.07.1998 – No. 23419)
Soils	Regulation on the Control of Soil Pollution and Lands Contaminated by Point Sources (OG: 08.06.2010 – No. 27605)
Rehabilitation	Regulation Concerning the Rehabilitation of the Lands Disturbed by Mining Activities (OG: 23.01.2010 – No. 27471)
Socio-economics	
Land Acquisition	Expropriation Law (OG: 08.11.1983 – No. 18215)
	Regulation on the Exchange of Treasury Lands in the Scope of Expropriation for Motorway Construction Purposes (OG: 30.01.2016 – No. 29609)
Water and Wastewater	
Water and Wastewater Management	Water Pollution Control Regulation (OG: 31.12.2004 – No. 25687)
	Surface Water Quality Regulation (OG: 30.11.2012 – No. 28483)
	Regulation on the Control of Pollution Caused by Dangerous Substances in and around the Water Bodies (OG: 26.11.2005 – No. 26005)
	Regulation on the Water Intended for Human Consumption (OG: 17.02.2005 – No. 25730)

II.2.1. EIA Process under Turkish EIA Regulation

Under Article 10, Environmental Law sets out the general scope of the Environmental Impact Assessment (EIA) procedure in Türkiye, indicating that institutions, agencies and establishments that lead to environmental problems as a result of their planned activities are obliged to prepare environmental impact assessment report or Project Information File. Based on this legal framework, the EIA Regulation was put into force for the first time after being published in the Official Gazette numbered 21489 and dated on February 7, 1993. Since then there had been several amendments in the first regulation and new EIA regulations were published in 2008, 2013 and 2014 repealing the former regulations in force. The latest EIA Regulation (2022 EIA Regulation) has been published in the Official Gazette dated 29.07.2022 and numbered 31907, which repealed the 2014 EIA Regulation.

Under its annexes, the EIA Regulation categorizes investments as projects subject to full EIA (Annex-1) and projects subject to screening-elimination criteria (Annex-2). This categorization is done based on the type of activity and/or plant capacity. If the planned investment is defined as an activity under Annex-1 of the EIA Regulation, a full EIA Report is required. For Annex-2 activities, first a Project Information File is prepared in accordance with a limited format specified in the Annex-4 of the EIA Regulation and the MoEUCC evaluates the need for a full EIA process for the project.

The categorization for motorway projects under Turkish EIA regulation is done according to the type or length of the road (km) as follows:

- Full EIA process is required for the following Annex-1 activities;
  - Highways and state motorways (Article 9-c).

- Limited EIA process is required to be conducted for the following Annex-2 activities;
  - Facilities with a production capacity of 5 tons/hour and above, producing shaped materials using cement or other binding materials (Article 18-c),
  - Asphalt plants (Article 22),
  - Provincial roads and ring roads (except neighborhood/village roads; Article 28-d),
  - Addition of tunnels to highways or railways (Article 28-e).

The Project's EIA Report had been prepared in March 2016, submitted to the MoEUCC, reviewed by the evaluation committee and EIA Positive decision had issued on August 17th, 2018 In accordance with the EIA legislation in force on the date when the Project EIA Positive Decision was given (2014 EIA Regulation), the EIA Report of the Project has the **vested right** of upholding its EIA Positive Decision validity **for 7 years** before the start of the construction works for the Project. The scope of the EIA Report that was subject to the positive decision basically covers the main route, its right of way, the access roads and not consists of the quarries, asphalt plants, cement plants, crushers, aggregate facilities, construction camps, etc. In other words, the associated and affiliated facilities that are needed for the realization of the Project, was not covered in the scope of EIA reviews. In addition to that for the sections of the current version of the Project that differ from the Project's EIA report approved in 2018, a Clearance Letter must be obtained from the relevant authorities (MoEUCC) by submitting a request detailing the said changes from the EIA report. As of April 2025, these changes are:

- Upon the request of the KGM administration, the Antalya-Alanya motorway will end at the Alanya center connection road (136+000 km point) instead of continuing to Gazipaşa district and connecting Gazipaşa and Alanya districts as stated in the Project's EIA report. However a new motorway consisting of approximately 5 kilometers of 2x2 lanes extending from Antalya-Alanya 136+000 km point to Alanya center and its connection road, which was not in the scope of the EIA but later included in the Project upon the request of the KGM administration;
- Establishment and operation of facilities not specified in the EIA report (quarries, storage areas, borrow pits, asphalt facilities, mechanical facilities and campsites) in order to meet the Project material and facility needs.

Any future changes in the Project that is not in the scope of the study area specified in the approved EIA of the Project also must be included in the clearance letter that will be submitted to the related authorities (MoEUCC).

Status of Environmental Permits and Licenses

The Project, the permit and licensing processes are still ongoing. As these processes are completed, the relevant information will be collected and presented as a table in this subsection.

Regarding main environmental permits and/or licenses that would be required for the Project are listed below:

Land Preparation and Construction Phase

- **Land Use**
  - Forestry permit
  - Permit for the use of pasturelands
  - Permit for the use of agricultural lands for non-agricultural purposes
  - Land use agreements with state authorities for state-owned lands
  - Expropriation of privately-owned lands

- **Construction and Camp Sites**

- Crossing permits/approvals for railroads, rivers, roads, canals, power supply lines, natural gas pipelines, etc.
- Workplace notification for Camp Sites
- Utility permits for the temporary connection to existing utilities (telecom, electricity, etc.)
- Fuel storage permit
- Permits for service roads
- Provisional operation certificate/environmental permit for the operation of ready mixed concrete plants
- Provisional operation certificate/environmental permit for the operation of asphalt plants
- Provisional operation certificate/environmental permit for the operation of crushing and screening plants
- Provisional operation certificate/environmental permit for the operation of mechanical plants

- **Water/Wastewater Management**
  - Provisional operation certificate/environmental permit for the operation of package wastewater treatment plants
  - Wastewater treatment plant identification certificate
  - Groundwater Utilization Permit

- **Waste Management**
  - Permit for temporary waste storage areas
  - Storage permit for the access amount raised by the cut
  - Waste management plan approval
  - Agreements with licensed waste management/disposal companies

- **Quarry Operation**
  - Raw material production/quarry operation license
  - Permission to use long vehicles

- **Blasting and Explosives Management**
  - Blasting permit
  - Permit for storage of explosives

- **Others**
  - Private security permit
  - EIA Process

II.2.2. Expropriation Process under Turkish Expropriation Law

As it is known, expropriation is the most widely used method for land acquisition. Article 46 of the Constitution of Republic of Türkiye explains that state and legal public entities, in cases of public benefit, are entitled to entirely or partially expropriate immovable properties in private possession, on condition that the real value of those immovable properties are paid in advance and in cash; and to establish easement (servitude) on these immovable properties in compliance with the procedures and principles set by expropriation law.

There are a large number of laws and regulations relevant to the implementation of land acquisition, which are namely; Expropriation Law (Law No: 2942), Turkish Civil Code (Law No: 4721), Cadastre Law (Law No: 3402), Forest Law (Law No: 6831), Environment Law (Law No: 2872), Municipalities Law (Law No: 5393), Pasture Law (Law No: 4342) and Village Law (Law No: 442) and several implementation regulations pertaining to the above-mentioned laws. Expropriation implementation activities based on Turkish laws and regulations can be summarized in line with the following stages:

- Project approval (public benefit decision),
- Preparation of expropriation plans,
- Identification of property owners and address investigation,
- Expropriation decision,
- Establishment of a “Valuation Commission” and the Valuation Process,
- Establishment of a “Negotiation Commission” and Purchasing Process.

Before describing the expropriation process, it should be underlined that the expropriation works for the Project will be carried out by KGM (government) as the related administrative authority according to the provisions of the BOT Contract and in accordance with the relevant provisions of the Expropriation Law (Law No: 2942). Project Company will comply with international standards regarding the execution of the expropriation works.

The process under Turkish Expropriation Law starts with the approval of relevant ministry/authority of the expropriation works on behalf the public interest. This decision is made public at the office of village/neighborhood mukhtar for 15 days and then it is regarded as “cutoff date”. After the approval of the project, expropriation plans are prepared. The actual size (surface area) and boundaries of the immovable properties and resources are determined by land surveys and a scaled (usually with a scale of 1/5.000) expropriation map is prepared. Expropriation maps shall demonstrate the boundaries, surface area and kind of immovable properties and resources to be expropriated. Mainly title deeds, taxes and state registers and/or external researches are used for identification of the owners.

Stage by stage (in accordance with the expropriation priority) the project responsible agency takes the “expropriation decision” for designated areas and informs/requests to the Land Titling and Cadastre Directorate to put an “expropriation note” on the register of the relevant property. The responsible agency establishes a Valuation Commission of at least three experts to determine the values of assets and resources. Valuation commission determines the unit and ceiling values of assets and resources to be expropriated. Then, responsible agency establishes a negotiation commission within its own entity to reconcile with property owners on the value. Each negotiation commission comprises of at least three members. The commission sends an official invitation letter to each property owner without declaring the value for the asset that was previously estimated by valuation commission. If the property owner(s) agrees on the predetermined value of the expropriated land(s), the expropriation fee is deposited to the rightful owners within 45 days after the meeting with the negotiation commission. If the land owner(s) takes the case to court thinking that he/she has suffered any kind of loss, the situation and the expropriation fee is re-evaluated in the court. The process is completed by calculating the total amount to be paid for the expropriated land(s) with the newly determined value and depositing the amount to the bank on behalf of the beneficiary within 15 days. The right holder (owner) has to bear the costs for the evacuation of the expropriated immovable property, such as costs for moving of personal goods, official transaction fees for purchase new land and/or new houses or related structures, with his/her own means.

Article 27 of the Expropriation Law states that; for the expropriation of immovable properties in situations for which Minister of Councils takes decision regarding the need or urgency for national defense in the scope of the implementation of the Law on National Defense Obligations (Law No: 3634) or during emergencies foreseen by special laws, the immovable property subject to expropriation may be seized by the related administration on condition that the procedures other than valuation shall be completed afterwards. In this process, following the request of the related administration, compensation amount for the immovable property and resource shall be appraised by the court within 7 days through the experts assigned as per Article 10 and 15 of the Expropriation Law. Seizure shall only be made following the invitation to be done in accordance with Article 10 and the amount is deposited to the bank specified in the announcement.

II.2.3. Resettlement Process under Turkish Resettlement Law

In Türkiye, resettlement activities of the government are regulated by Resettlement Law (No: 5543). The Resettlement Law deals with the families applying to related governmental agencies in the project region and requesting government assisted resettlement. Law also covers the procedure of resettlement of immigrant families coming from other countries, as well as that of nomadic families.

Resettlement assistance of the government is provided to entitled families upon their request while expropriation compensation payments are paid to all individuals holding immovable properties in the project area. Three types of resettlement can be applied according to the choices and requests of affected families. Entitlement criteria related with resettlement whose lands will be expropriated are defined by Implementation Regulations of Resettlement Law. According to the Regulation, owners requesting the resettlement must be residing at the project affected area, and they must earn annually less than 18 times monthly minimum official wages, and they should be seen as a family and must not be a civil servant.

Agricultural Resettlement: Agricultural resettlement is implemented through providing a family with one or more of the following; agricultural land at the amount of envisaged in special resettlement project, house, management building, and animal for income generation, agricultural devices and tools, workbench and loans.

Non-agricultural Resettlement: This type of resettlement is implemented through providing a family with one or more of the following: building plot at the amount provisioned in special resettlement project, house, devices, tools, workbench and loans.

Physical Settlement: This type of resettlement is implemented through providing construction credit support to a family within the amount of loan determined by the Ministry (MoEUCC) with the aim of re-building (moving) of villages because of unsuitability of a village center or consolidating of villages because of dispersed settlement or villages which are fragmented as a result of disasters; after selling land (house plot) from village development areas to people in need.

Article 12 of Resettlement Law refers to the resettlement of persons whose immovable properties are expropriated and specifies eligibility criteria for government assisted resettlement as follows:

(1) Due to the construction of a dam, an area adjacent to the dam, an area under protection, airport, highway, railway, plant and other facilities related to national economy and defense will be erected by public institutions and organizations; and due to the implementation of special laws and in order to protect historical and natural valuables;

a) The families who have to leave their locations/places as a result of partial or full expropriation of their immobile properties,

b) The families who do not own any immovable property, but who reside in the expropriation area at least for three years before the beginning of the calendar year, in which the resettlement planning studies were commenced, will be resettled to the locations/places indicated by the MoEUCC according to the provisions of this Law, provided that they request.

(2) However, the families who own immovable properties to be expropriated but left their places before the commencement date of resettlement planning studies shall not be resettled. Within the last three years as of this date, the families who sold their immobile properties without any compulsory situation and did not purchase immovable property with the equal or higher value shall not be resettled even if they did not leave their places. The compulsory situations mentioned above shall be determined by the regulations.

(3) Among the families residing in the expropriation area, those who are affected from the expropriation implemented by the public institutions and organizations, can be resettled by the Ministry to a location indicated within their village boundaries upon their written application if they do not want to be resettled by the government in any other place, provided that the suggestion of relevant Governorate and the approval of the Ministry of Internal Affairs are obtained.

(4) Among the families included in the scope of the this article, and requested to be resettled by the Government; the families who do not apply within the ninety day following the ending date of the announcement of resettlement, and the families who do not commit to deposit the amount determined by the MoEUCC from their expropriation compensation they received or will receive, or their full expropriation compensation and additional increase awarded by court in the case that the amount of expropriation compensation is lower than the amount (determined by the Ministry) into the account of the Central Account Unit of the Ministry, shall not be resettled.

Article 9 of Resettlement Law explains the resettlement assistance (which is similar to World Bank Standards) as follows:

(1) The immigrants, nomads, the persons whose places/grounds are expropriated and persons who are decided to be relocated by the reason of the national security shall be resettled in cities, towns and villages by means of providing the following through debiting/repayment according to the provisions of this Law, and pursuant to the plan and the project (specific) prepared by the MoEUCC;

a) At first, house and its' house- plot (for building),
b) For craftsmen, artisans and tradesmen: work place and its' building plot and operation credit to enable them providing for their livelihood,
c) For farmers, land, necessary agricultural inputs, agricultural structures or plot of structure, and in kind and in cash operation and equipment credits as envisaged in agricultural resettlement project (specific),
d) In case of the request of the right holder families (entitled to resettlement), resettlement credits can be given to the families collectively or individually, if the house, work place and agricultural land are found by themselves and their suggestions are approved by MoEUCC.

(2) Annual operation and equipment credits provisioned in agricultural resettlement projects (specific) shall not be paid to the families who did not request the mentioned credits within two years following the transfer of their agricultural lands.

(3) For immigrants accepted to enter the country according to this Law, as of the date they pass (enter) the border gates with their used goods which are exempt of customs; and for the people whose grounds(immovable properties) are expropriated and for those who are resettled due to national security and for the nomads, as of time when they are transferred to their resettlement areas; they shall be provided the support of medical help, accommodation, food, fuel and the support of clothing (for once only) for persons in need, and gratuitous assistances for temporary re-settlement for those whose immovable properties are expropriated; these supports shall be provided according to the time, amount and the conditions specified in the regulations of the Law.

(4) Transportation (moving) of those (families) mentioned above to the resettlement areas (sites) shall be provided free of charge by the government according to the "Transportation (moving) Project" to be prepared (specifically) by the Ministry.

From the international standards point of view of, another important point is the allocation of expenditure regarding land acquisition and resettlement under a single/same budget item. Resettlement Law Article 33 states that the resettlement allowance will be allocated from the budget of the institution responsible for expropriation.

It should be noted that in the selection of the Project route, physical displacement has been avoided to the extent the highway design criteria allowed. In the scope of the land acquisition process to be conducted for the potentially limited number of parcels on which buildings/structures located within the expropriation corridor according to the current design, it is essential that the related authorities to aim the conduct acquisition process based on negotiated settlements to be established in accordance with the Expropriation Law thus the affected families do not apply to government and request government assisted resettlement.

Resettlement activities in Turkey are governed by the Resettlement Law (Law No. 5543, 2006) and it's Implementing Regulation. This legislation provides for state-assisted resettlement in both rural and urban areas and is typically applicable to large-scale infrastructure projects — such as dam developments — that may require the relocation of entire settlements, including district centers. The Resettlement Law is implemented by the Ministry of Environment, Urbanization and Climate Change (MoEUCC) and its authorized institutions.

The Resettlement Law is not applicable to highway projects implemented by KGM, as these typically involve the physical displacement of a limited number of structures, dispersed along the highway route. In such cases, cash compensation is provided by KGM in accordance with the provisions of the Expropriation Law (Law No. 2942, as amended).

For this Project, the relocation or resettlement of affected households and businesses, whether owners or users will be carried out in conformity with the Expropriation Law, implemented by KGM. This process will be undertaken in collaboration with the Special Purpose Vehicle (SPV) through the implementation of a Relocation Action Plan (RAP).

II.2.4. Cultural Heritage Management under Conservation of Cultural and Natural Assets Law

According to the Conservation of Cultural and Natural Assets Law (Law no: 2863), all cultural and natural properties requiring protection are considered as state property. As stated in the same law, the

Ministry of Culture and Tourism and its local branches (Boards for Preservation of Cultural Assets, Museums) are the main national government institutions who have the authority of conducting the works of identification and registration of cultural assets and defining the conditions of conservation. In this respect, Antalya Regional Board for Preservation of Cultural Assets is the sole competent authority within the scope of the Project.

The Project area is under the responsibility of Antalya Regional Board for Conservation for Cultural Assets. The Project is bound legally to follow the decision taken and shall be taken by the preservation board. Information on the relevant regional board for the preservation of cultural assets is provided in Table II.2.

Antalya Museum Directorate, and Antalya - Alanya Museum Directorate is responsible for officially supervising actions such as official monitoring and/or further activities (trial pits, salvage excavation, re-routing and remote sensing surveys) in line with the decisions taken by Antalya Regional Board for Preservation of Cultural Assets. They will also prepare the conclusion reports about actions to be taken and submit to Preservation Board for re-evaluation of the sites. Information on the museum directorates is presented in Table II.3.

The Project management is responsible for conservation of immovable cultural assets in case of discovery, and implementation of plans minimizing the adverse impacts of the construction activities over these assets and keeping relevant government institutions informed. In this respect, the Project management is obliged to prepare a plan which comprises of the construction activities and their impacts on the archaeological and immovable cultural assets located within the boundaries of the Project construction and its impact area and to propose methods for eliminating or minimizing the negative impacts of construction activities over the concerned sites for the opinion of the directorate of Preservation Board.

II.3. Relevant International Agreements and Protocols

Turkish national policy on protection of environment, cultural heritage and conservation of biological resources has been constituted on the base of relevant international agreements that Türkiye has signed or ratified. Relevant environmental international agreements and conventions that have been ratified by Türkiye are listed below.

- European Cultural Convention (1957),
- European Convention on the Protection of the Archaeological Heritage (1969),
- Convention on the Conservation of Migratory Species of Wild Animals (Bonn Convention) (1972),
- International Convention for the Prevention of Pollution from Ships (also known as Marpol 73/78) (1973),
- The Convention for the Protection of Marine Environment and the Coastal Region of the Mediterranean (Barcelona Convention) (1981),
- Convention on the Means of Prohibiting and Preventing the Illicit Import, Export and Transfer of Ownership of Cultural Property (1981)
- Convention on Long Range Transboundary Air Pollution (CLRTAP) (1983),

- Convention for the Safeguarding of the Intangible Cultural Heritage (2006),
- Stockholm Convention on Persistent Organic Pollutant (POPs) (2009).

II.4. Applicable International Environmental and Social Standards and Guidelines

International financial institutions follow specific policies and procedures for the assessment and management of environmental and social impacts of the projects they finance. The relevant environmental and social requirements of these institutions are primarily based on the World Bank Group (WBG) Safeguard Policies. For private sector financing, the Environmental, Health and Safety (EHS) Guidelines and the Performance Standards on the Environmental and Social Sustainability developed by the WBG/International Finance Corporation's (IFC) have become the one of the most important international requirements. These standards have also been adopted by the major international private banks through their commitment to the Equator Principles (EPs) a risk management framework designed to ensure that financed projects are developed in a socially and environmentally responsible manner.

The ESIA Report to be prepared for the Project will be in accordance with the Equator Principles (IV) and IFC's Performance Standards on Environmental and Social Sustainability and general as well as sector-specific Environmental, Health and Safety Guidelines. Key points of each international principle, standard and guideline is provided in the following sections. It should be noted that when Turkish (host country) regulations differ from the levels and measures presented in the EHS Guidelines, the Project will aim to achieve whichever is more stringent.

II.4.1. Equator Principles IV

The Equator Principles (EPs) is a risk management framework, adopted by financial institutions, for determining, assessing and managing environmental and social risk in projects and is primarily intended to provide a minimum standard for due diligence to support responsible risk decision-making. The EPs apply globally to all industry sectors.

Most of the large private international banks (so called Equator Principles Financial Institutions-EPFIs) have officially adopted these principles (According to EP IV, published November 2019 and came into force in October 2020), summarized below, to ensure that the projects financed or advised by them are developed in a manner that is socially responsible and reflect sound environmental management practices.

Principle 1: Review and Categorization

When a Project is proposed for financing, the EPFI will, as part of its internal environmental and social review and due diligence, categorize the Project (Category A, B or C) based on the magnitude of its potential environmental and social risks and impacts, including those related to Human Rights, climate change, and biodiversity. Such categorization is based on the IFC's environmental and social categorization process.

Principle 2: Environmental and Social Assessment

The EPFI will require the client to conduct an Assessment process to address, to the EPFI's satisfaction, the relevant environmental and social risks and impacts of the proposed Project. The Assessment Documentation should propose measures identified to minimize, mitigate and offset/resolve the adverse impacts of risks on workers, affected communities and the environment.

The client is expected to include assessments of potential adverse Human Rights impacts and climate change risks as part of the ESIA or other Assessment, with these included in the Assessment Documentation. The client should refer to the (United Nations Guiding Principles on Business and Human Rights) UNGPs when assessing Human Rights risks and impacts, and the Climate Change Risk Assessment should be aligned with Climate Physical Risk and Climate Transition Risk categories of the Task Force on Climate-related Financial Disclosures (TCFD).

Principle 3: Applicable Environmental and Social Standards

The Assessment process should, in the first instance, address compliance with relevant host country laws, regulations and permits that pertain to environmental and social issues.

Principle 4: Environmental and Social Management System and Equator Principles Action Plan

For all Category A and Category B Projects, the EPFI will require the client to develop or maintain an Environmental and Social Management System. Further, an Environmental and Social Management Plan (ESMP) will be prepared by the client to address issues raised in the Assessment process and incorporate actions required to comply with the applicable standards.

Principle 5: Stakeholder Engagement

For all Category A and Category B Projects, the EPFI will require the client to demonstrate effective Stakeholder Engagement as an ongoing process in a structured and culturally appropriate manner with Affected Communities and, where relevant, Other Stakeholders. For Projects with potentially significant adverse impacts on Affected Communities, the client will conduct an Informed Consultation and Participation process. The client will tailor its consultation process to: the risks and impacts of the Project; the Project's phase of development; the language preferences of the Affected Communities; their decision-making processes; and the needs of disadvantaged and vulnerable groups. This process should be free from external manipulation, interference, coercion and intimidation.

Principle 6: Grievance Mechanism

For all Category A and, as appropriate, Category B Projects, the EPFI will require the client, as part of the Environmental and Social Management System, to establish a grievance mechanism designed for use by Affected Communities and Workers to receive and facilitate resolution of concerns and grievances about the Project's environmental and social performance. The grievance mechanism is required to be scaled to the risks and impacts of the Project.

Principle 7: Independent Review

For all Category A and, as appropriate, Category B Projects, an Independent Environmental and Social Consultant will carry out an Independent Review of the Assessment Documentation including the ESMPs, the Environmental and Social Management System, and the Stakeholder Engagement process documentation in order to assist the EPFI's due diligence, and assess Equator Principles compliance.

Principle 8: Covenants

An important strength of the Equator Principles is the incorporation of covenants linked to compliance. For all Projects, where a client is not in compliance with its environmental and social covenants, the EPFI will work with the client on remedial actions to bring the Project back into compliance.

The client will covenant in the financing documentation to comply with all relevant host country environmental and social laws, regulations and permits in all material respects. EPFIs will take reasonable measures to ensure that all existing environmental and social obligations continue to be included in the new financing documentation.

Principle 9: Independent Monitoring and Reporting

For all Category A and, as appropriate, Category B Projects, in order to assess Project compliance with the Equator Principles after Financial Close and over the life of the loan, the EPFI will require independent monitoring and reporting. Monitoring and reporting should be provided by an Independent Environmental and Social Consultant; alternatively, the EPFI will require that the client retain qualified and experienced external experts to verify its monitoring information.

Principle 10: Reporting and Transparency

For all Category A and, as appropriate, Category B Projects, the client will ensure that, at a minimum, a summary of the ESIA is accessible and available online; and the client will publicly report GHG emission levels during the operational phase for Projects. In addition to these, the EPFI will encourage the client to share commercially non-sensitive Project-specific biodiversity data with the Global Biodiversity Information Facility (GBIF) and relevant national and global data repositories, using formats and conditions to enable such data to be accessed and re-used in future decisions and research applications.

II.4.2. IFC Standards and Guidelines

The following subsections outline the relevant IFC standards and guidelines applicable to the Project, including the Performance Standards on Environmental and Social Sustainability, the General Environmental, Health, and Safety (EHS) Guidelines[1], the EHS Guidelines for Toll Roads, and the EHS Guidelines for Construction Materials Extraction.

II.4.2.1. Performance Standards on Environmental and Social Sustainability

IFC published its current Policy on Environmental and Social Sustainability in 2012. Within the framework of this Policy, it applies a comprehensive set of Performance Standards to manage social and environmental risks and impacts and to enhance development opportunities in its private sector financing in the member countries eligible for financing. The Performance Standards may also be applied by other financial institutions electing to apply them to projects in emerging markets.

The following eight Performance Standards establish the requirements that the client has to meet throughout the life of an investment supported by IFC or other relevant financial institution using these Standards.

[1] https://www.ifc.org/content/dam/ifc/doc/2010/2012-ifc-performance-standards-en.pdf

Performance Standard 1: Assessment and Management of Environmental and Social Risks and Impacts

The main objective of Performance Standard 1 is to ensure that clients of the IFC identify, assess, and manage the environmental and social risks and impacts associated with their projects. This standard emphasizes a systematic approach to understanding and addressing potential adverse effects on the environment and affected communities.

PS1 stresses the importance of engaging with and consulting relevant stakeholders throughout the project life cycle. This includes obtaining input from affected communities, considering their concerns, and providing opportunities for meaningful participation. The project is required to disclose certain information regarding its environmental and social performance. This transparency helps build trust among stakeholders and enables informed decision-making.

Compliance with PS1 is a prerequisite for IFC financing, and it establishes a framework for responsible and sustainable project development. The IFC provides guidance and support to clients to help them meet the requirements of Performance Standard 1.

Performance Standard 2: Labor and Working Conditions

PS2 focuses on promoting employment opportunities and ensuring employees have fair and favorable working conditions. This includes issues such as working hours, wages, benefits and the right to form and join workers' organizations.

This standard emphasizes the necessity of a safe and healthy working environment. This standard includes identifying and mitigating potential occupational health and safety hazards, providing access to necessary facilities, and creating emergency preparedness and response plans.

Performance Standard 3: Resource Efficiency and Pollution Prevention

This standard provides guidelines for managing the environmental impact of projects financed by IFC. These guidelines; It includes environmental assessment, management of environmental and social risks, prevention and reduction of pollution, waste management, emissions, resource efficiency, public health and safety, biodiversity protection and sustainable natural resource management.

It emphasizes the importance of conducting an environmental assessment to determine potential project impacts, taking into account environmental, social and health issues. It requires the Project Sponsor to establish an Environmental and Social Management System (ESMS) to manage and reduce environmental and social risks throughout the project lifecycle. As part of this system, pollution prevention measures are adopted and cleaner production technologies are supported. It encourages the reduction, reuse and recycling of waste generated by the project. It also requires the Project Sponsor to minimize air emissions.

Performance Standard 4: Community Health, Safety and Security

This standard aims to ensure that the project activity does not pose unacceptable risks to the health and safety of employees, affected communities, and project visitors and to ensure the safety of people and assets.

IFC PS4 includes occupational health and safety, community health and safety, emergency preparedness and response, and stakeholder engagement. The standard requires projects to identify and assess potential health and safety risks and implement measures to prevent accidents and injuries. It also assesses and addresses the potential health and safety impacts of the project on local communities. PS4 requires projects to establish security arrangements to ensure the safety of project personnel, affected communities, and project assets.

Performance Standard 5: Land Acquisition and Involuntary Resettlement

The purpose of PS5 is to ensure that individuals and communities affected by a project are fairly compensated and assisted in their efforts to improve or, at the very least, restore their standard of living if adversely affected by land acquisition or involuntary resettlement. This standard aims to facilitate communication with affected communities; conduct social assessments including the displacement or loss of livelihoods endeavor to restore or enhance livelihoods, provide equitable compensation for assets and properties affected by the project, avoid force eviction, and safeguard cultural heritage sites and monuments that may be affected.

Performance Standard 6: Biodiversity Conservation and Sustainable Management of Living Natural Resources

This standard focuses on the Conservation of Biodiversity and Sustainable Natural Resource Management. The aim of the standard is to promote the conservation of biodiversity and the sustainable management of natural resources within the scope of the project.

According to this standard, projects should avoid operating within protected areas. In exceptional cases where this is not possible, measures should be taken to minimize and mitigate impacts, and the conservation objectives of the protected area should be supported. The ecosystem services provided by natural habitats should be acknowledged, and sustainability should be preserved whenever possible. Communication with relevant stakeholders, including local communities and users involved, is essential for maintaining the biological diversity and sustainable natural resource management of the Project.

Performance Standard 8: Cultural Heritage

The aim of PS8 is to ensure that projects respect and take into account the cultural heritage of affected communities and avoid negative impacts on cultural resources. This standard provides a comprehensive identification and evaluation of cultural heritage, including tangible and intangible elements related to the project area, communication with affected communities, preventing the impact on cultural heritage, minimizing the impact if it cannot be prevented, and informing the affected public.

To summarize briefly, the objectives of Performance Standard 1 are;

- To identify and evaluate environmental and social risks and impacts of the project,
- To adopt a mitigation hierarchy to anticipate and avoid, or where avoidance is not possible, minimize, and where residual impacts remain, compensate/offset risks and impacts to workers, Affected Communities, and the environment,
- To promote improved environmental and social performance of clients through the effective use of management systems,

- To ensure that grievances from Affected Communities and external communications from other stakeholders are responded to and managed appropriately,
- To promote and provide means for adequate engagement with Affected Communities throughout the project cycle on issues that could potentially affect them and to ensure that relevant environmental and social information is disclosed and disseminated.

Performance Standards 2 through 8 describe potential environmental and social risks and impacts that require particular attention. Where environmental or social risks and impacts are identified, the client is required to manage them through its Environmental and Social Management System (ESMS) consistent with Performance Standard 1, which is applicable to all projects that may have environmental and social risks and impacts. IFC's Performance Requirements/Standards applicability to the Project is given in Table II.4.

Table II.4 IFC's Performance Standards and their Applicability to the Project

IFC Performance Standards (2012)		Applicability
PS 1	Assessment and Management of Environmental and Social Risks and Impacts	Yes
PS 2	Labor and Working Conditions	Yes
PS 3	Resource Efficiency and Pollution Prevention	Yes
PS 4	Community Health, Safety and Security	Yes
PS 5	Land Acquisition and Involuntary Resettlement	Yes
PS 6	Biodiversity Conservation and Sustainable Management of Living Natural Resources	Yes
PS 7	Indigenous Peoples	No
PS 8	Cultural Heritage	Yes

II.4.2.2. General Environmental, Health, and Safety (EHS) Guidelines

In addition to the IFC Performance Standards, the International Finance Corporation (IFC) has developed a series of Environmental, Health, and Safety (EHS) Guidelines, which represent internationally, recognized Good International Industry Practice (GIIP). Among these, the General EHS Guidelines, published in April 2007, provide overarching guidance that is applicable across all industry sectors and are intended to be used in conjunction with sector-specific guidelines where relevant.

The General EHS Guidelines outline performance levels and measures that are achievable in new or modernized facilities using current technology and economically feasible methods. The document offers comprehensive guidance on the management of environmental impacts, occupational health and safety, and community health and safety, covering all phases of a project lifecycle, including construction, operation, and decommissioning.

For infrastructure projects such as this one, the General EHS Guidelines form the basis for ensuring compliance with international best practices and complement the requirements of applicable national legislation. In addition to the General Guidelines, sector-specific EHS Guidelines, such as those for Toll Roads and Construction Materials Extraction, are also applicable and are discussed in the following sections.

Relevant provisions from both the General and sector-specific EHS Guidelines have been taken into account during the ESIA process and have been integrated into the Project's environmental and social management plans to ensure alignment with international standards and the requirements of potential lenders.

II.4.2.3. Environmental, Health, and Safety (EHS) Guidelines for Toll Roads

The Environmental, Health, and Safety (EHS) Guidelines for Toll Roads, published by the International Finance Corporation (IFC) in April 2007, provide sector-specific guidance on the management of environmental and social risks associated with the development and operation of toll road and highway infrastructure projects, including bridges and overpasses.

These guidelines complement the IFC General EHS Guidelines (2007) and are intended to be applied jointly. While the General Guidelines address overarching EHS issues relevant across all industries, the Toll Roads guideline focuses on sector-specific concerns.

Key topics covered include:

- Road safety management, including traffic control and accident prevention measures;
- Air emissions and noise impacts during both construction and operational phases;
- Surface water and soil pollution mitigation from storm water runoff and spills;
- Waste management practices, particularly during construction;
- Community health and safety, including risks to road users and nearby populations;
- Biodiversity and ecosystem impacts, particularly where road alignment intersects with natural habitats or protected areas.

The Project will ensure alignment with these guidelines as part of its commitment to Good International Industry Practice (GIIP), particularly in compliance with the environmental and social requirements of international financing institutions.

II.4.2.4. Environmental, Health, and Safety (EHS) Guidelines for Construction Materials Extraction

The Environmental, Health, and Safety (EHS) Guidelines for Construction Materials Extraction, published by the International Finance Corporation (IFC) in April 2007, provide guidance on the management of environmental and social risks associated with the extraction of construction materials. These materials include aggregates, limestone, slate, sand, gravel, clay, gypsum, feldspar, silica sands, quartzite, and dimension stones.

These guidelines are applicable to both stand-alone extraction projects and to quarrying activities that support larger construction or infrastructure developments, such as highways, bridges, and civil works. In the context of this Project, where construction materials may be sourced from external or project-associated quarries, the application of these guidelines is particularly relevant.

The document outlines Good International Industry Practices (GIIP) for managing impacts such as:

- Land disturbance and landscape alteration, including progressive rehabilitation and closure planning;
- Airborne dust emissions, noise, and vibrations from blasting or mechanical extraction;

- Surface and groundwater impacts, including sedimentation and contamination;
- Occupational health and safety risks associated with excavation, transport, and processing of raw materials;
- Community health and safety, particularly in relation to haul roads, blasting, and dust dispersion.

Implementation of the recommendations in this guideline will support the Project's efforts to mitigate potential environmental and social impacts related to construction material sourcing and align with the standards expected by international lenders.

II.4.3. EU Directives

The environmental and social assessment of motorway projects within the European Union is guided by a comprehensive set of directives aiming to protect environmental quality, natural resources, public health, and community well-being. These directives establish the legal framework for evaluating potential impacts and ensuring that mitigation and monitoring measures are implemented effectively throughout the project lifecycle.

The Environmental Impact Assessment (EIA) Directive (2011/92/EU, amended by 2014/52/EU) requires that major infrastructure projects, such as highways, undergo a systematic assessment of their potential environmental effects before development consent is granted. This includes evaluating impacts on biodiversity, soil, water, air, climate, landscape, and human health. Public participation is a central requirement of the directive, ensuring that communities and stakeholders have the opportunity to provide input at an early stage in project planning.

Closely related to the EIA Directive is the Strategic Environmental Assessment (SEA) Directive (2001/42/EC), which applies to plans and programs that set the framework for future development projects, including road networks. It ensures that environmental considerations are integrated at the strategic decision-making level, particularly in national or regional transportation planning.

With regard to air quality, the Ambient Air Quality Directive (2008/50/EC), recently revised by Directive (EU) 2024/2881, establishes limit values for key pollutants such as PM_{10}, $PM_{2.5}$, NO_2, and SO_2. These pollutants are commonly associated with traffic emissions and construction activities. For example, the new air quality standards to be met by 2030 include a limit of 20 µg/m³ for PM10 and 10 µg/m³ for $PM_{2.5}$ (annual averages), 20 µg/m³ for NO_2, and hourly and daily thresholds for SO_2. Compliance with these limits is essential to protect human health and the environment.

The Environmental Noise Directive (2002/49/EC) requires the development of noise maps and action plans for major roads, railways, and agglomerations. Projects must assess potential noise impacts during both construction and operational phases, with particular attention to night-time levels. Member States define their own noise limit values; however, the directive obligates project developers to prevent, reduce, and mitigate harmful noise exposure through appropriate design and barrier measures.

In terms of waste management, the Waste Framework Directive (2008/98/EC) establishes the waste hierarchy, emphasizing prevention, reuse, recycling, and recovery over disposal. Road construction projects must include strategies for managing construction and demolition waste, ensuring compliance with recovery targets and minimizing environmental risks associated with landfill disposal or hazardous waste.

Lastly, the Environmental Liability Directive (2004/35/EC) enforces the "polluter pays" principle. Developers are financially and legally responsible for preventing and remedying environmental damage caused by their activities. This includes damage to water resources, protected species and habitats, and land contamination. Appropriate risk management and emergency response plans must be developed as part of the overall environmental and social management system.

II.4.4. AIIB Environmental and Social Framework

The Project will be implemented in compliance with the Asian Infrastructure Investment Bank (AIIB) E&S Framework (ESF) approved in February 2016, amended in February 2019, May 2021, November 2022, and lastly June 26, 2024. The AIIB Environmental and Social Framework, effective since 2021, outlines the Bank's commitment to ensuring environmentally and socially sustainable outcomes in all its operations.

The Environmental and Social Policy (ESP) sets out AIIB's vision, principles, and mandatory environmental and social requirements for project implementation. It ensures that projects avoid, minimize, or mitigate adverse impacts while enhancing positive outcomes. There are three core ESSs:

- ESS 1: Environmental and Social Assessment and Management: Requires borrowers to conduct comprehensive environmental and social impact assessments and to develop appropriate management plans.
- ESS 2: Involuntary Resettlement: Ensures that any displacement is minimized and affected persons are compensated and assisted in restoring their livelihoods.
- ESS 3: Indigenous Peoples: Protects the rights and cultural heritage of indigenous communities that may be affected by the project.

In the standards described above, all standards except ESS-3 are applicable within the scope of the project. In line with the AIIB Environmental and Social Framework (ESF), the project will undertake a structured Environmental and Social Impact Assessment (ESIA) process. This includes stakeholder engagement, public disclosure, grievance redress mechanisms, and the development of an Environmental and Social Management Plan (ESMP). Furthermore, if the project involves any land acquisition or affects vulnerable groups, detailed Resettlement Action Plans (RAPs) must be prepared and disclosed in accordance with AIIB guidelines.

Accordingly, the project's legal framework will incorporate the AIIB ESF as a binding component, requiring the Borrower and the implementing agencies to ensure full compliance throughout the project lifecycle.

II.4.5. Other Applicable Standards and Guidelines

In addition to the primary lender standards described in previous sections, several additional international standards and good practice guidelines have been considered during the preparation of this assessment, in order to ensure alignment with Good International Industry Practice (GIIP). These standards provide technical direction and support enhanced environmental and social performance throughout the project lifecycle.

World Bank Group Environmental, Health and Safety (EHS) Guidelines

The World Bank Group has developed a series of EHS Guidelines that serve as technical reference documents with general and industry-specific guidance. These documents are widely recognized within the international financing community and are referenced in both the World Bank's

Environmental and Social Framework and IFC's Performance Standards. The following guidelines have been considered as relevant to this motorway project:

- General EHS Guidelines (2007)[2]
- EHS Guidelines for Toll Roads (2007)[3]
- EHS Guidelines for Construction Materials Extraction (2007)[4]
- IFC/EBRD Guidance Note on Worker Accommodation: Processes and Standards (2009)[5]

Other International Standards and Guidelines

In addition to the EHS Guidelines, the following international standards and principles have also been considered during the Environmental and Social Impact Assessment (ESIA) process:

- OECD Recommendation of the Council on Common Approaches for Officially Supported Export Credits and Environmental and Social Due Diligence (2016)6
- International Labor Organization (ILO) Core Conventions, which address fundamental principles and rights at work, including freedom of association, elimination of forced and child labor, and non-discrimination
- United Nations Guiding Principles on Business and Human Rights (UNGPs)7, which outline the corporate responsibility to respect human rights
- Voluntary Principles on Security and Human Rights8, providing guidance on how companies can maintain the safety and security of their operations while respecting human rights

These supplementary standards serve to enhance the project's environmental and social performance and ensure compatibility with the expectations of international financial institutions and stakeholders.

II.4.6. Project Categorization

As part of its environmental and social due diligence process for proposed investments, the International Finance Corporation (IFC) implements an environmental and social categorization system to evaluate the type, scale, and significance of potential risks and impacts. This categorization enables IFC to determine the scope and level of environmental and social review required, as well as the disclosure obligations in accordance with its Access to Information Policy.

The categorization framework is structured as follows:

- **Category A:** Projects that are expected to have significant adverse environmental and/or social risks and impacts that are diverse, irreversible, or unprecedented. These typically involve complex or large-scale operations—such as major infrastructure, extractive industries, or heavy industrial facilities—where the potential impacts extend beyond the project site and require comprehensive assessment and mitigation planning.
- **Category B:** Projects with potential limited adverse environmental and/or social risks and impacts that are generally site-specific, predictable, and reversible. These impacts are

[5] https://documents1.worldbank.org/curated/en/604561468170043490/pdf/602530WP0worke10Box358316B01PUBLIC1.pdf
[6] https://legalinstruments.oecd.org/public/doc/280/280.en.pdf
[7] https://www.ohchr.org/sites/default/files/documents/publications/guidingprinciplesbusinesshr_en.pdf
[8] https://www.voluntaryprinciples.org/wp-content/uploads/2023/10/Voluntary-Principles_ENGLISH.pdf

usually easier to manage through standard mitigation and management measures. Category B projects still require due diligence but at a less detailed level than Category A projects.

- **Category C:** Projects that are likely to have minimal or no adverse environmental or social risks and impacts. These activities typically do not require further environmental and social assessment beyond screening.

IFC, in its Guidance Note 1 on the Assessment and Management of Environmental and Social Risks and Impacts, states that "For certain projects, and particularly for greenfield investments and projects (including, but not limited to, major expansion or transformation-conversion activities) involving specifically identified physical elements, aspects and facilities that are likely to generate potentially significant adverse environmental and social risks and impacts, the client should conduct a comprehensive full-scale ESIA". Accordingly, ***Antalya-Alanya Motorway Project*** would be categorized as "**Category A**" based on WB/IFC's criteria and thus a comprehensive full-scale ESIA report would be required for the Project.

To provide further evaluation in the scope of national and international categorization criteria in consideration of existing indicative lists of Category A project, the screening criteria defined in the European Union's (EU) EIA Directive and Turkish EIA Regulation is also considered as described below.

According to the EU's EIA Directive, all projects listed in Annex I of the Directive, are considered as having significant effects on the environment and require an EIA (*http://ec.europa.eu*). "Construction of motorways and express roads" and "Construction of a new road of four or more lanes, or realignment and/or widening of an existing road of two lanes or less so as to provide four or more lanes" are listed under Article 7 of the EIA Directive's Annex I list. Thus, the ***Antalya-Alanya Motorway Project would be categorized as an Annex I activity according to the EU's EIA Directive***.

As Türkiye gained a candidate country status in EU access process in 1999, the Turkish EIA Regulation has been harmonized with the EU's EIA Directive with several revisions and amendments made on the regulation since then. In parallel to the categorization approach of EU's EIA Directive, the Turkish EIA Regulation requires an EIA Report to be prepared for the activities listed under Annex-1 of the EIA Regulation. As mentioned in Section II.2.1, "Highways and state motorways (Article 8-c)" and "Construction of express roads having four and more lanes (Article 8-ç)" are listed as Annex-1 activities thus; same with the categorization under EU's EIA Directive, Antalya-Alanya Motorway Project would be an Annex-1 activity according to the Turkish EIA Regulation as well.

Taking into account the project categorization frameworks and criteria set forth by the IFC, the EU EIA Directive, and the Turkish EIA Regulation, the Antalya-Alanya Motorway Project has been identified as a **Category A** project due to the scale and nature of its potential environmental and social impacts. Accordingly, a full-scale Environmental and Social Impact Assessment (ESIA) has been prepared to meet the requirements of international financial institutions and relevant national and regional legislation.

II.5. Project Standards

The Project Sponsor is committed to full compliance with the applicable requirements of national legislation, as well as the Equator Principles (EPs), the International Finance Corporation (IFC) Performance Standards, and the associated General and sector-specific Environmental, Health and Safety (EHS) Guidelines.

In cases where discrepancies exist between national legal requirements and the standards, measures, or threshold values defined by the IFC Performance Standards or EPs, the Project will adopt the more stringent requirement in order to ensure alignment with Good International Industry Practice (GIIP) and the expectations of international financial institutions.

All relevant environmental and social standards, limits, and performance requirements applicable to the Project have been identified and incorporated into the respective thematic sections of this ESIA Report. These include, but are not limited to, standards related to air quality, noise, vibration, surface and groundwater quality, waste management, biodiversity, land acquisition, labor conditions, and community health and safety.

A summary of the applicable project standards is provided in Table II.5.

Table II.5 Project Standards

II.6. Permits

In this section, a comprehensive table has been prepared to summarize the current status of all permits and licenses relevant to the Project. The table includes both the permits that have already been obtained and those that have been applied for, covering the entire scope of the planned highway construction activities.

It is important to note that the table reflects the status as of the time of this ESIA report preparation. A more detailed Permit Register will be developed separately and maintained throughout the Project lifecycle. This register will be regularly monitored and updated to ensure compliance with national legal requirements and lender standards.

A summary of the permits obtained and in process within the scope of the project is given in Table II.6 below.

Table II.6 Summary of Permits

Authority	Related Subject	Comment	Date
Ministry of Environment, Urbanization and Climate Change	Environmental Impact Assessment (EIA) Positive Decision	Construction must begin within 7 years under the scope of the EIA decision. As of March 2025, construction activities have started within the scope of the project, and the decision remains valid.	17.08.2018
Ministry of Agriculture and Forestry, General Directorate of Forestry Management	Forest Permits for Highway Route	Forest Permits have been obtained for the highway route with a validity period of 49 years.	19.02.2025
Serik Forest Management Directorate	Forest Permit for Concrete Plant (KM 55+400)	An application for a Forest Permit for the Concrete Plant facility at KM 55+400 was submitted on 03.06.2025. It was reviewed and accepted, and the permit is valid from 21.08.2025 to 14.10.2027.	21.08.2025
	Excavated Material Storage Permit for Depot-2 (KM 52+544)	An application for a Forest Permit for the Excavated Material Storage Depot-2 (KM 52+544) was approved and is valid from 11.07.2025 to 11.07.2030.	11.07.2025
Taşağıl Forest Management Directorate	Forest Permits for Concrete Plant, Mechanical, Asphalt Plant, Warehouse, Workshop	Forest Permits for the Concrete Plant, Mechanical, Asphalt Plant, Warehouse, and Workshop (KM 59+400) were obtained under approval dated 15.02.2025 .	15.02.2025
	Camp Site-1	The approval dated 26.05.2025 was signed for the main camp site (KM 64+300) and was delivered to the Operations Directorate on 28.05.2025 for the commitment notes and field delivery procedures to be carried out.	28.05.2025
	Land use permit for Construction Site Layout, Warehouse, Workshop	The approval dated 26.05.2025 was signed for the Construction Site Settlement, Warehouse and Workshop (KM 87+500), and was delivered to the Operations Directorate on 04.06.2025 for the commitment notes and field delivery procedures to be carried out.	04.06.2025
	Land use permit for Concrete Plant, Mechanical, Asphalt Plant	The approval dated 26.05.2025 was signed for the Concrete Plant, Mechanical, Asphalt Plant (KM 87+700) and was delivered to the Operations Directorate on 28.05.2025 for the commitment notes and site delivery procedures to be carried out.	28.05.2025

Authority	Related Subject	Comment	Date
	Land use Permit for Concrete Plant	The area where the Concrete Plant (KM 80+400) will be located is not located in the Forest area, and the report requested by the Ministry within the scope of the application for non-agricultural use was prepared by the Provincial Directorate of Agriculture and Forestry and submitted with a letter dated 21.05.2025, and approval is awaited.	In Progress
		The approval dated 26.05.2025 was signed for the Concrete Plant (KM 89+700) and was delivered to the Operations Directorate on 28.05.2025 for the commitment notes and site delivery procedures to be carried out.	28.05.2025
General Directorate of Forestry	Land use Permit for Concrete Plant	The Land Use Permit application for the Concrete Plant (KM 99+200) was submitted to the General Directorate on 20.05.2025. It has been approved and is valid from 21.08.2025 to 14.10.2027.	21.08.2025
	Alternative-1 (Concrete Plant, Mechanical, Asphalt Plant, Construction Site Layout)	The application file was returned with the letter dated 13.03.2025 and delivered to the 13th Regional Directorate of Highways on 14.03.2025. It was determined that the application for Construction Site-9 was made by mistake while the application for Construction Site-10 should have been made. The application is under evaluation at the General Directorate.	In Progress
Antalya Regional Directorate of Forestry	Alternative-2 (Concrete Plant, Mechanical, Asphalt Plant, Construction Site Layout	The Forest Permit application for Alternative-2 (KM 124+300) was submitted to the Regional Directorate of Forestry on 26.05.2025. It has been reviewed and accepted, and is valid from 11.08.2025 to 14.10.2027.	11.08.2025
	Excavated Material Storage Permit for Depot-6 (KM 61+500)	The Forest Permit application for Depot-6 (KM 61+500) was revised following a site visit on 06.04.2025, during which it was requested that an access road be incorporated into the project scope. The revised application was submitted to the Antalya Regional Directorate of Forestry on 30.05.2025, and it has been accepted with validity from 30.06.2025 to 30.06.2030.	30.06.2025
	Excavated Material Storage Permit for Depot-11 (KM 74+360)	The Forest Permit application for Depot-11 (KM 74+360) was submitted to the Antalya Regional Directorate of Forestry on 30.05.2025. It has been approved and is valid from 04.06.2025 to 04.06.2030.	04.06.2025
	Excavated Material Storage Permit for Depot-14 (KM 76+240)	The Forest Permit application for Depot-14 (KM 76+240) has been approved and is valid from 11.07.2025 to 11.07.2030.	11.07.2025

Authority	Related Subject	Comment	Date
	Excavated Material Storage Permit for Depot-31 (Alternative to Depot 17 and located at KM 88+000)	The Forest Permit application for Depot-31 (KM 88+000) was submitted to the Regional Directorate of Forestry on 26.05.2025. It has been approved and is valid from 30.06.2025 to 30.06.2030.	30.06.2025
	Excavated Material Storage Permit for Depot-32 (Alternative to Depot 17 and located at KM 88+000)	The Forest Permit application for Depot-32 (alternative to Depot-17, KM 88+000) has been approved and is valid from 11.07.2025 to 11.07.2030.	11.07.2025
	Excavated Material Storage Permit for Depot-18 (KM 95+410)	The Forest Permit application for Depot-18 (KM 95+410), for which the technical report had been completed, was submitted to the Regional Directorate and reviewed. As the requested area overlapped with a TEDAŞ transmission line, formal consent was required, and a consent request letter was issued on 09.05.2025. The permit was subsequently approved and is valid from 24.06.2025 to 24.06.2030.	24.06.2025
	Excavated Material Storage Permit for Depot-19 (KM 95+450)	The Forest Permit application for Depot-19 (KM 95+450), for which the technical report had been completed, was submitted to the Regional Directorate and reviewed. Since the requested area overlapped with both a TEDAŞ power line and a Türk Telekom communication line, formal consents were required, and a consent request letter was issued on 09.05.2025. The permit was subsequently approved and is valid from 24.06.2025 to 24.06.2030.	24.06.2025
	Excavated Material Storage Permit for Depot-20 (KM 98+290)	The Forest Permit application for Depot-20 (KM 98+290), for which the technical report had been completed, was submitted to the Regional Directorate and reviewed. As the requested area overlapped with a TEDAŞ transmission line, formal consent was required, and a consent request letter was issued on 09.05.2025. The permit was subsequently approved and is valid from 24.06.2025 to 24.06.2030.	24.06.2025
	Excavated Material Storage Permit for Depot-22 (KM 107+850)	The Forest Permit application for Depot-22 (KM 107+850), for which the technical report had been completed, was submitted to the Regional Directorate and reviewed. Since the requested area overlapped with both a TEDAŞ transmission line and a designated canyon permit area, formal consent was required, and a consent request letter was issued on 09.05.2025. The permit was subsequently approved and is valid from 30.06.2025 to 30.06.2030.	30.06.2025

Authority	Related Subject	Comment	Date
	Excavated Material Storage Permit for Depot-24 (KM 113+050)	The Forest Permit application for Depot-24 has been approved and is valid from 04.07.2025 to 04.07.2030.	04.07.2025
	Excavated Material Storage Permit for Depot-27 (KM 124+500)	The Forest Permit application for Depot-27 was prepared and submitted to the Antalya Regional Directorate of Forestry, and the review process was completed. The permit has been approved and is valid from 13.08.2025 to 13.08.2030.	13.08.2025
Alanya Forest Enterprise Directorate	Excavated Material Storage Permit for Depot-26 (KM 123+000)	The Forest Permit application for Depot-26 (KM 123+000) is pending, as completion of the technical report and submission to the Regional Directorate has not yet been finalized. Based on discussions with the Forest Operations Chief, it was indicated that an alternative area will be requested, as the current site falls within a productive forest zone and is likely to be evaluated unfavorably.	In Progress
	Excavated Material Storage Permit for Depot-28 (KM 127+000)	The completion of the technical report and the submission of the file to the Regional Directorate is currently pending. Following discussions with the Forest Operations Chief, it was indicated that an alternative location would be required, as the current area lies within a productive forest zone and is expected to be evaluated unfavorably.	In Progress
	Excavated Material Storage Permit for Depot-30 (KM 132+720)	A Forest Permit application for Depot-30 (KM 132+720) was submitted on 08.07.2025. Based on discussions with the Forest Operations Chief, it was indicated that an alternative site would be requested, as the current location falls within a productive forest area and is likely to be evaluated unfavorably.	In Progress
Presidential Decision	Expropriation Decision	Within the scope of the Antalya-Alanya Motorway and Connection Roads Project numbered 9708, published in the Official Gazette numbered 32857 dated 30 March 2025, it has been decided by the General Directorate of Highways to urgently expropriate the relevant real estates.	29.03.2025
State Hydraulic Works (DSİ)	Wastewater Discharge Point	The discharge of effluent from the domestic wastewater treatment plant with a capacity of 200 m^3/day, planned for the construction site located within the boundaries of Taşağıl Neighborhood, Manavgat District, on an area of 66,449.77 m^2 and accommodating 1,000 workers, into the Kaymazboğazı Stream has been approved by the 13th Regional Directorate of State Hydraulic Works (DSİ).	26.05.2025
	Groundwater and Surface Water	The Water for Use Permit (non-drinking purposes) for Camp Site-2 (Taşağıl, KM 59+400) was obtained on 07.03.2025, and valid throughout the Project.	07.03.2025

Authority	Related Subject	Comment	Date
Directorate of Environment, Urbanization and Climate Change	Wastewater Treatment Plant Design Document Approval	For onsite wastewater treatment plants/units, an approval will be obtained as per Wastewater Treatment/Deep Sea Discharge Project Approval Circular dated 04.03.2014 and numbered 2014/7.	In Progress
Ministry of Agriculture and Forestry, General Directorate of Forestry Management	Forest Permits for Surplus Material Storage Areas (SMSA)	Forest Permits have been obtained for 2 SMSA sites. Applications for 20 SMSA Forest Permits have been submitted and official procedures are ongoing at the Regional Directorate of Forestry.	In Progress
General Directorate of Mining and Petroleum Affairs (MAPEG)	Material Quarries	Licenses have been obtained from the General Directorate of Mining and Petroleum Affairs (MAPEG) for six quarries (Sarıabalı, Karakaya, Saburlar, Karamanlar, Çakış, and Bademliyar). For Uzunlar, a Raw Material Extraction License (License No. 07/2025-07) was completed on 03.06.2025 and is valid until 03.06.2030. For Soğukpınar, a Raw Material Production Permit (License No. 07/2025-08) was completed on 27.05.2025 and is valid until 27.05.2030. The application process for Kuruçay Quarry is still ongoing at MAPEG. Additionally, an application for the Dikmen Quarry has been submitted to the Antalya Governorship Investment Monitoring and Coordination Directorate, as this quarry falls under the jurisdiction of the Antalya Governorship.	In Progress
General Directorate of Highways (KGM)	Expropriation	Expropriation Plans for the entire route have been approved. Valuation survey studies have been completed for the entire route except for the Çakallar and Akdam regions. Valuation reports are being entered into the General Directorate of Highways (KGM) system	In Progress
	Excavated Material Storage Permit for Depot-3 (KM 59+580)	The Forest Permit application file was submitted to the Regional Directorate of Forestry. During a site visit conducted on 06.04.2025 at other depot areas, it was requested that access roads be incorporated into applications lacking such connections. Accordingly, the return of previously submitted files was officially requested by letter dated 16.05.2025 for revision. The revised permit file was prepared and submitted to the 13th Regional Directorate of Highways on 03.06.2025. The permit was subsequently approved on 06.08.2025 and is valid until 06.08.2030.	06.04.2025
General Directorate of National Property	Treasury Allocations	Applications for treasury allocation have been made for all treasury lands along the project route, and the process is ongoing at the General Directorate of National Property.	In Progress

III. PROJECT DESCRIPTION

Antalya-Alanya Motorway Project (the Project) is one of the two sub-projects that constitute the Afyonkarahisar-Alanya Motorway Project and is designed to connect Serikli and Alanya districts through Manavgat district of Antalya province. The Project will enhance the existing transportation network services with surrounding provinces (Burdur, Muğla, Konya, Isparta, Karaman and Mersin). Various environmental, social, and technical studies have been conducted along the initial route of the Project tendered by the KGM. Based on these studies, the route was optimized, incorporating engineering practices and addressing environmental and social considerations, particularly issues of involuntary and economic resettlement, before being finalized. According to the current design as of April 2025, the total length of the motorway, which will consist of a dual carriageway with predominantly three lanes and partially two lanes in each direction (3x2 and 2x2), is 117.8 kilometers, including both the main carriageway and access roads.

Ministry of Transport, and Infrastructure (former Ministry of Transport, Maritime Affairs and Communications), General Directorate of Highways (KGM), as the owner of the Antalya-Alanya Motorway Project, has tendered for a contract in accordance with the Law on Implementation of Some of the Investments and Services in the Framework of Build, Operate and Transfer Model (Law No: 3996). Following the tendering process, KGM has awarded Antalya-Alanya Otoyolu İnşaat Yatırım ve İşletme A.Ş. (AAOİAŞ or the Project Sponsor) with a Build, Operate and Transfer (BOT) contract for the implementation of the Project. Limak has been designated as the main contractor for the Project and will henceforth be referred to as the Contractor. Table III.1 provides the approximate distances of the Motorway according to the current design.

Table III.1. Information of the Motorway

Start Location	End Location	Main Road (Motorway)	Access Roads	Total
Km 52+000	Km 136+000	84+000	33+800	117+800

In accordance with the terms of the BOT contract signed between the KGM and the Project Sponsor, the Project includes financing, planning/design, building/construction, operation, full range of maintenance and repair works during the operation period and transfer of the Motorway to the KGM at the end of the contract duration free from any debt or commitment and in a well-maintained, operating, in-service condition, without any charge. The Project Sponsor's rights to operate maintain and repair the Motorway will expire at the end of the contract duration.

According to the BOT Contract, the contract period covers both construction and operation phases. In accordance with the relevant provisions of the BOT contract, guaranteed minimum traffic (in passenger vehicle equivalent (PCE)) for the Antalya-Alanya Motorway will be presented in PCE/day once the traffic projection is completed.

III.1. Project Design Criteria

Motorways are access-controlled highways that have two or more traffic lanes in each direction and provide uninterrupted flow, on which opposing traffic is separated by a median and collection of tolls are performed at designated points. Motorway has been designed in accordance with the KGM's technical specifications for motorways. The design criteria specified by the KGM for the Antalya-Alanya Motorway is listed in Table III.2.

Table III.2. Motorway Design Criteria

Design Criteria Component	Unit	Motorway (Main Carriageway)	Access Roads
Speed Limit	km/hour	120	100
Width of the Traffic Lane	m	3.75	3.50
Number of Traffic Lanes	-	2x3	2x2
Shoulder Width (Emergency Lane)	m	3	3
Side Width for Guardrails (At Fill)	m	1	1
Refuge Width	m	5	3
Shoulder Width for Central Reserve	m	1	1
Baseline Design Side Slope (Minimum Superelevation)	%	2.5	2.5
Maximum Superelevation	%	6	6
Minimum radius for Horizontal Curve	m	1,000	600
Radius for Horizontal Curve (Minimum Superelevation=2.5%)	m	3,400	2,050
Radius for Horizontal Curve with no Superelevation Requirement	m	5,000	4,500
Minimum vertical Clearance for Bridges	m	5	5

Source: Highway Design Handbook (December, 2016)

A typical cross-section for the Motorway's main carriageway is provided in Figure III.1. As can be seen from this cross-section, the Motorway will be a dual carriageway having 3 lanes in each direction. Each of the 6 lanes will have a width of 3.75 meters. The central reserve will be 7 meters (3.5 m x 2) plus 2 meters of lined shoulder (1 m in each side of the reserve). At the outer side of the traffic lanes in each direction, there will be 3 meters of lined shoulders that will serve as emergency strips and 1 meter of shoulder edge side strips. Thus, the total width of the platform consisting of central reserve, lined shoulder, traffic lanes, emergency line, and shoulder edge side strips for both directions will be 39.5 meters. There will be also ditches as required in both sides of the main carriageway.

Access roads will have a different design when compared to main carriageway. Access roads will be composed of 2 lanes in each direction. Each of the 4 lanes will have a width of 3.5 meters. The central reserve in access roads will be 5 meters (2.5 m x 2) plus 2 meters of lined shoulder (1 m in each side of the reserve). At the outer side of the traffic lanes in each direction, there will be 3 meters of lined shoulders that will serve as emergency strips and 1 meter of shoulder edge side strips. Thus, the total width of the access roads' platform consisting of central reserve, lined shoulder, traffic lanes, emergency line, and shoulder edge side strips for both directions will be 29 meters. Typical cross-section for the Motorway's access roads is presented in Figure III.2. Additional drawings for the Motorway's carriageway and access roads are presented in Annex-1.

Design speed at the interchange arms will vary between 50 and 80 km/hour depending on the radius of the horizontal curve. Minimum relative slope will be 0.4% while maximum slope will vary between 0.5% and 1%. Additional design criteria are listed below:

- For all types of topographical models, side slope for standard coating shall be 2.5% and superelevation will not exceed 6%.
  - Vertical clearance shall be minimum 5 meters for all roads passing over or under the Motorway.
- Embankment (fill) slopes (s) shall be determined based on the height (h) of the embankment as follows:
  - For h<1,5 m ; s=4:1;
  - For 1,5 m<h<3 m ; s=3:1;
  - For h>3 m ; s=2:1;
- Cutting slopes shall be determined based on the results of geotechnical studies.
- Minimum bench width shall be 5 meters on the embankments and cuttings.
- Horizontal (i.e. shoulder lines, traffic lines, parking lines, etc.) and vertical signing (i.e. traffic signs, plates, etc.) of the Motorway will be in accordance with KGM's technical specifications (i.e. dimensions, color, material, reflectivity features, numbering, information figures, location of signs, etc.).

Although the Project's specifications state a design speed of the main road (motorway) 120 km/h for the main road (motorway), in line with the current developments and the requirements of KGM, the Project design speed was increased to 140 km/h for the main road and 110 km/h for the access roads. All necessary design and construction works for the Project have been and will continue to be carried out based on the Project's updated design speed values. The updated criteria for Project roads are detailed in Table III.3.

Table III.3. Updated Design Criteria of the Project

Design Criteria Components	Unit	Motorway	Access Road
Speed Limit	km/h	140	110
Strip Width	m	3.75	3.50
Banquette Width (Emergency Shoulder Width)	m	3	3
Refuge Banquette Width	m	1	1
Refuge Width	m	7	5

The total width of the Motorway's main carriageway, measuring 39.5 meters, is calculated in detail below:

Central reserves: 3.5 m x 2 = 7 m.
Lined shoulder in each side of the reserve: 1 m x 2 = 2 m.
Dual carriageway with 3 lanes in each direction: 3.75 m x 6 = 22.5 m.
Outer side lined shoulders (emergency strips): 3 m x 2 = 6 m.
Shoulder edge side strips: 1 m x 2 = 2 m.

Total Length = [(3.5m x 2) + (1m x 2) + (3.75m x 6) + (3m x 2) + (1m x 2)] = 39.50 m.

The total width of the Motorway's access roads, measuring 29 meters, is calculated in detail below:

Central reserves: 2.5 m x 2 = 5 m.
Lined shoulder in each side of the reserve: 1 m x 2 = 2 m.
Dual carriageway with 3 lanes in each direction: 3.5 m x 4 = 14 m.
Outer side lined shoulders (emergency strips): 3 m x 2 = 6 m.
Shoulder edge side strips: 1 m x 2 = 2 m.

Total Length = [(2.5m x 2) + (1m x 2) + (3.5m x 4) + (3m x 2) + (1m x 2)] = 29 m.

The Motorway will be a dual carriageway with three lanes (3x2) along the 84 kilometers stretch, and the access roads will have two lanes (2x2) over the 33.8 kilometers length[1]. Table III.4 presents the permanent access roads that are defined as project components and connected to interchanges along the motorway. Access roads that are temporary in nature and considered auxiliary facilities for use during the construction phase are addressed separately in Section III.2.4.

Table III.4. Details on the Access Roads

Interchanges/Access Roads	Location on the Route (Motorway Km)	Connected Road	Access Road Length (Km)
Serik Interchange	52+324	D-400 State Road	10+746
Taşağıl Interchange	66+288	D-400 State Road	2+620
Manavgat Interchange	77+030	D-400 State Road	6+809
Manavgat East Interchange	100+737	D-400 State Road	3+460
Alarahan Interchange	117+581	Okurcalar-Alara Road	2+835
Konaklı Interchange	133+436	Konaklı-Güzelbağ Road	1+600
Alanya West Interchange	136+000	D-400 State Road	5+705
Total (Access Road)			**33+775**

[1] It should be noted that the environmental and social baseline characterization, maps and assessments provided in this report are based on the design as of April 2025.

III.2. Description of Activities and Project Components

The main activities to be conducted before the commissioning of the Antalya-Alanya Motorway will include the land acquisition, land preparation and construction stages. In this scope, before the start of construction works, the lands on which the Motorway and its components will be located and will be acquired in line with the applicable Turkish laws and regulations. In the scope of the Antalya-Alanya Motorway Project, KGM is the authority responsible from the implementation of expropriation works in accordance with the national Expropriation Law. For the forestry lands, treasury lands and other state-owned lands, necessary permits, land use permits and/or easement rights will be obtained by KGM from the related authorities in the scope of applicable legislation.

The works on the planned route is carried out in several main steps. The first step, which is substructure works, starts with earthwork activities such as topsoil stripping, poor soil excavations, and cut-fill operations. Following the earthwork activities, engineering structures such as bridges, underpasses, overpasses, retaining walls, culverts, concrete pipes, and viaducts are constructed. The next step involves pavement work, which includes forming the subbase, base, asphalt layer, and concrete or parquet paving for specific situations[2]. After the substructure and pavement work is completed, finishing operations are carried out, including the placement of horizontal and vertical traffic signs, as well as the installation of guardrails and fences. Upon completion of the park and service areas, maintenance and operation centers, and toll collection systems, the Motorway will be ready for the tests and commissioning. This standard procedure will be followed in the construction of the Project.

When the Project intersects existing infrastructure, including sewage, electricity, water supply, telecommunication, and natural gas lines, these utilities will be relocated in the scope of the construction works so that no permanent interruption would occur on the services provided to local users. Similarly, some of the existing roads may need to be temporarily closed and the users of the affected roads will be directed to the service roads to ensure local transportation services are not interrupted.

During the operation phase, road maintenance and repair works will be conducted by the Project Sponsor until the end of contract duration. Maintenance works will involve routine maintenance, winter maintenance and periodic maintenance works. Periodic maintenance, involving large-scale repairs of the superstructures, is expected to be required every 10 years. Maintenance and repair works will be performed in accordance with the operation, maintenance and repair standards and technical specifications. The rights of the Project Sponsor to operate maintain and repair the Motorway will expire at the end of the contract duration, when the motorway shall be transferred to the KGM free from any debt or commitment and in a well-maintained, operating, in-service condition, without any charge. Number of vehicles subject to passage fee will be identified by means of electronic passage systems to be installed in line with the specifications. Technical and legal supervision and control of the construction and operation works/periods will be executed by the personnel or independent consulting firms to be assigned by the KGM. Special structures will be inspected and released/signed off during site surveillance.

According to the IFC Performance Standards (2012), “Associated Facilities” are defined as facilities that:

- are not financed as part of the Project;
- are necessary for the Project’s viability; and
- would not have been constructed or expanded without the Project.

[2] *http://www.kgm.gov.tr*

As part of the ESIA process, an assessment was carried out to evaluate whether any external facilities could be considered “associated facilities” in line with the IFC definition. The review covered potential infrastructure and services typically linked to large-scale projects, including access roads, energy transmission lines, water supply systems, wastewater treatment plants, and waste management facilities.

The assessment results indicate that the Antalya-Alanya Motorway Project has been designed and financed as a self-sufficient and stand-alone infrastructure project. The alignment connects directly to the existing D-400 State Road at the Serik and Alanya interchanges. The Project does not depend on the development, upgrade, or expansion of third-party infrastructure for its functionality. In addition, all critical operational elements including interchanges, service areas, drainage systems, and other supporting facilities are included within the scope and financing of the Project.

The Antalya–Alanya Motorway Project is one of the two sub-projects of the Afyonkarahisar–Alanya Motorway and is designed independently from the Afyonkarahisar–Antalya section to connect the districts of Serik and Alanya through Manavgat within Antalya Province. The Project constitutes a stand-alone infrastructure directly connected to the existing D-400 State Road at the Serik and Alanya interchanges. Its implementation does not require any third-party infrastructure development, upgrade, or expansion, and its operational viability is fully ensured within its own scope and financing.

Based on the above assessment, the Project does not involve any facilities that meet the IFC criteria for associated facilities. The motorway is a self-contained and operationally viable development, independent of external infrastructure beyond its direct connections to the national road network.

III.2.1. Construction Camp Sites and Quarries

During the construction works, temporary construction facilities/sites will be needed. These facilities and sites include construction campsites, quarries, plants and service roads. Following the completion of construction activities, temporary facilities will be decommissioned. Table III.5 provides a list of the campsites, quarries and plants to be used in the scope of the Project. A map showing the locations of construction compounds is provided in Figure III.3.

Table III.5. Locations of the Borrow Pits/Quarries and Plants

Location	Province	District	Nearest Neighborhood	Description of the Site / Plant	Area (m²)	Capacity Information / Operation Period
Km 53+800	Antalya	Serik	Sarıabalı	Sarıabalı (AO-1) Borrow Pit	249,000	375 m³/hour
						36 months

III.2.2. Storage Sites

In the scope of road construction works, excavated materials are planned be used in the filling operations wherever the characteristics and the quality of the materials are suitable. When there is a surplus of excavated materials, excess material will be needed to be stored at designated storage areas. In this regard, list of storage sites identified to be used for the motorway is presented in Table III.6.

Table III.6. List of Storage Sites Planned to be used

Location		Description of the Site	Capacity Information (m^3)	Planned Capacity Usage (m^3)
Km 52+544	Antalya, Serik	D-2	736,660.28	470,850.34

III.2.3. Engineering Structures

Main engineering structures in the Project includes the viaducts, bridges, overpasses and underpasses, culverts, etc. In accordance with KGM's specifications, the design and engineering of the structures have prioritized safety, durability, aesthetics, environmental compatibility, construction and maintenance costs, constructability, and construction duration. The design of these structures has utilized the Standard Specifications for Highway Bridges published by the American Association of State Highway and Transportation Officials (AASHTO). For the seismic calculations, the Standard Specifications for Highway Bridges (1977) have been used. Where required, Project-specific revisions have been or will be made, with the approval of KGM, to adequately adapt these specifications to the Project. Summary of the total number of engineering structures for sections of the Project is provided in Table III.7. It should be noted that the design work is ongoing and will be updated accordingly in the subsequent reports until the design freeze stage is reached.

Table III.7. Summary of the Engineering Structures for the Project

Engineering Structure	Number
Viaduct	16
Bridge	22
Culvert	305
Interchange	25
Overpass	56
Underpass	43
Tunnel	5

Viaducts are substructures constructed on girders/beams. They are effectively used to cross challenging topographical and/or geotechnical conditions while providing protection for the corresponding habitats (e.g. forests, wetlands, river valleys, etc.). Viaducts are particularly suitable for narrow, steep-sided valleys and offer several environmental advantages. They minimize land usage and fragmentation within a valley by allowing watercourses and existing nature conservation interests to continue flowing beneath the structure. Additionally, viaducts help maintain connectivity for species movement; and preserve views up and down the valley (Viaducts are substructures constructed on girders/beams. They are effectively used to cross challenging topographical and/or geotechnical conditions while providing protection for the corresponding habitats (e.g. forests, wetlands, river valleys, etc.). Viaducts are particularly suitable to for narrow, steep-sided valleys and they offer have several environmental advantages. They as they can minimize land take usage and fragmentation within a valley by allowing watercourses and any existing nature conservation interests to continue flowing beneath under the structure. Additionally, viaducts help maintain connectivity for species movement; and retain preserve views up and down the valley (European Cooperation in the Field of Scientific and Technical Research; Luell et.al. 2003). Viaducts to be constructed for the Motorway are listed in Table III.8.

Table III.8. Viaducts to be Constructed for the Motorway

Viaducts		Length (m)	Location on the Route (Motorway Km)	
			Start Location	End Location
Viaduct-1	Left	789.38	Km 55+456.830	Km 56+246.208
	Right	799.27	Km 55+437.903	Km 56+237.175

Culverts are hydraulic engineering and service structures of small-scale that are used to ensure passage/drainage of perennial surface water bodies, creeks formed as a result of precipitation through the road body and also passage of pedestrians, cyclists/motorcyclists and animals. Culverts of different dimensions to be constructed for the Motorway are listed in Table III.12.

Table III.12. Culverts to be Constructed for the Motorway

	Right	873	Km 88+671.000	Km 89+544.000

III.2.4. Temporary Access Roads

Temporary access roads are planned to facilitate the safe and efficient transportation of materials, equipment, and personnel between key construction areas (e.g., tunnels, viaducts, bridges) and material supply points (e.g., concrete plants, quarries) during the construction phase of the Project. These access roads are preliminarily identified based on current construction planning needs and are intended to support the initial phases of construction.

It is important to emphasize that the identified routes represent potential access roads, and their actual use will depend on the evolving requirements and progress of construction activities. Accordingly, the final set of roads to be used may differ from the current list, and additional routes may be introduced or some of the identified routes may not be utilized at all.

In selecting these access roads, the project team has prioritized the use of existing roads-including public roads, forest roads, and rural paths-with the aim of minimizing new land disturbance. No new roads have been planned unless absolutely necessary. Some of the identified routes, such as forest roads, are already established and in use. However, minor modifications or maintenance may be required, depending on their condition and suitability for construction traffic.

Table III.15 lists the temporary access roads identified for use during the construction of the Project. It includes the unique identifier for each route, the origin and destination points, the corresponding chainage interval along the motorway, and the closest neighborhood or settlement to each route.

There are a total of 79 temporary access roads identified for the project. These routes generally originate from concrete plants or quarries, such as Concrete Plant 1 to Concrete Plant 6, as well as TOY4a and Çengel Stream Material Quarry, and terminate at key construction sites including viaducts, tunnels, interchanges, and structural work zones along the motorway. The access roads are distributed across the entire alignment, but a greater concentration is observed in the chainage

intervals between KM: 68+000 and KM: 111+000, corresponding to areas with higher densities of engineering structures and multiple active work fronts.

Proximity to neighborhoods is particularly relevant in this context, as temporary access roads may intersect or run adjacent to residential areas, thereby increasing the potential for disturbances such as noise, dust, and traffic safety risks. The presence of these settlements necessitates careful planning and mitigation to minimize adverse impacts on local communities. Relevant mitigation measures are presented in detail in Chapter XV.

The spatial distribution and alignment of the temporary access roads are illustrated in the series of maps provided in Figure III.18 through Figure III.24. Each figure corresponds to a specific section of the motorway, organized by chainage intervals, and displays the connections between material supply points and associated construction sites.

Additionally, the transport of cement and rebar to each concrete plant will be conducted via seven dedicated delivery routes. These designated routes are depicted in Figure III.25.

Table III.15. Transportation Routes Between Material Supply Points and Construction Sites

Road ID	Start	End	Location	Closest Neighborhood
Yol-1	Concrete Plant 1	T1-Entrance (Structures)	Between 52+000–55+000	Sarıabalı

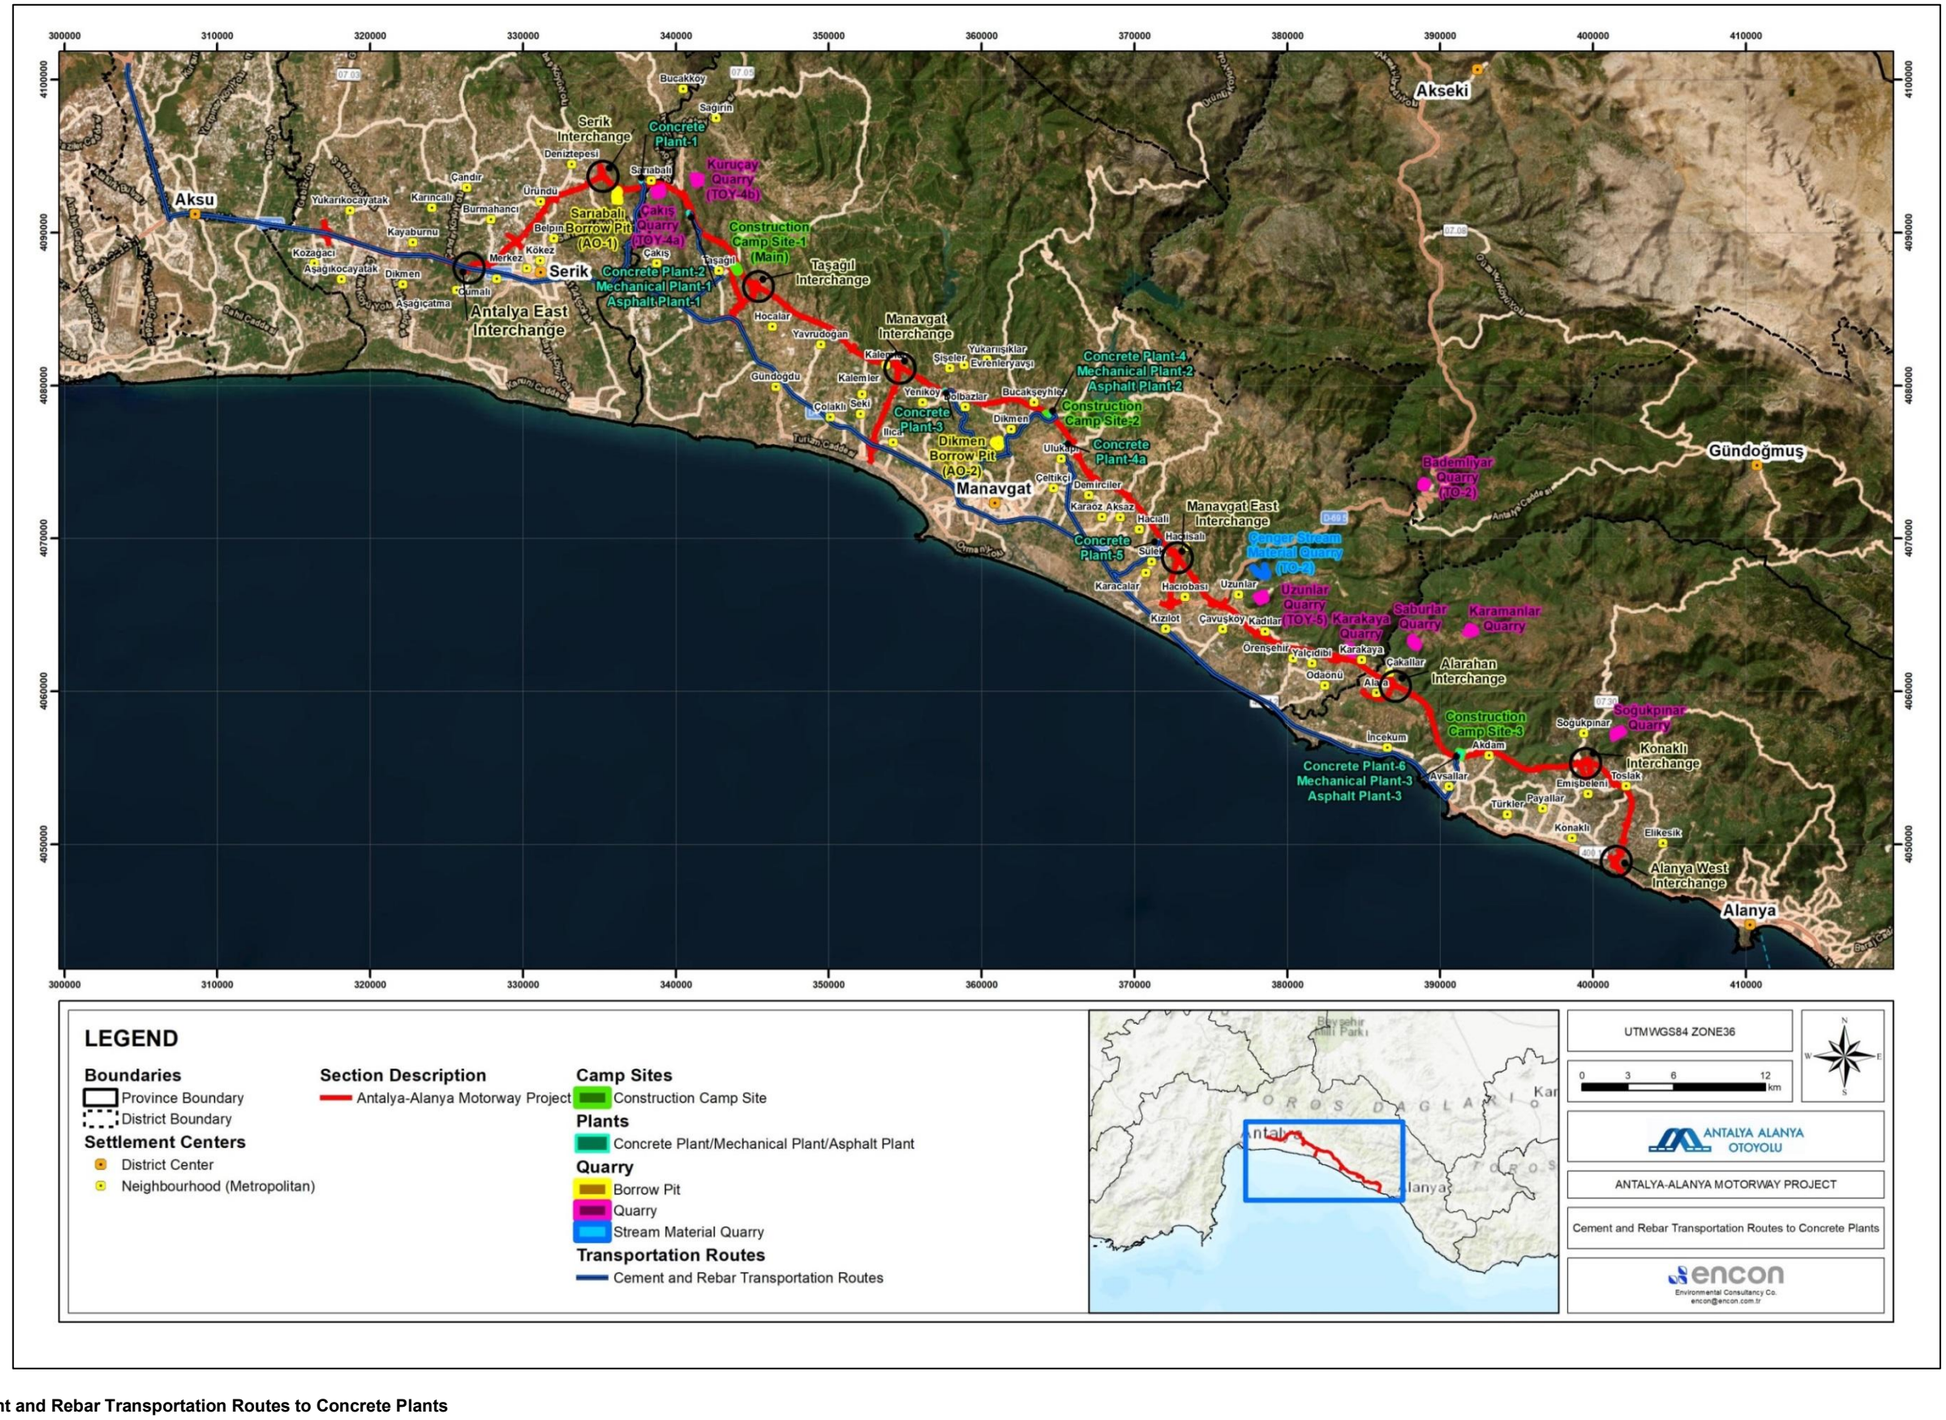

Figure III.25. Cement and Rebar Transportation Routes to Concrete Plants

III.2.5. Toll Collection Areas

Since the Motorway will be operated with an access-controlled system, all entry and exit points will be equipped with toll collection stations with fast pass system (HGS) infrastructures.

Toll plazas, toll passage lanes, operation building(s), transformer building(s) and parking areas will be available at the toll collection areas. Toll plazas and passage lanes will be designed to have sufficient capacity for the existing and future traffic projections. Communication infrastructure will be provided to allow data transfer to traffic management systems. An example layout drawing for toll stations is provided in Figure III.26.

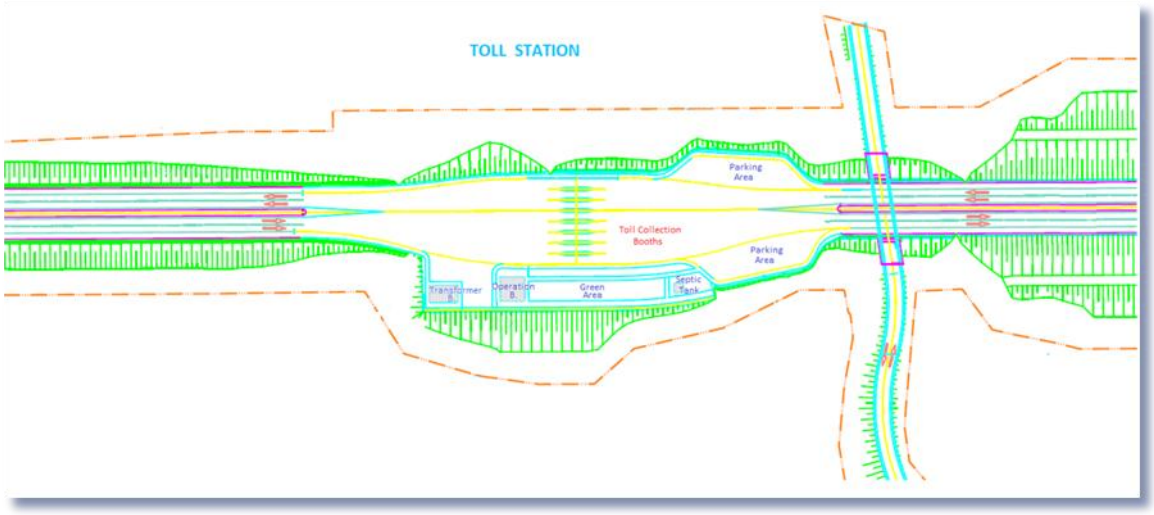

Figure III.26. Example Layout of a Toll Station

III.2.6. Service Areas

Service areas are facilities constructed to international standards at intervals of 20-50 km along the motorways. They are designed to meet the needs of users continuously (24 hours a day, 7 days a week) and efficiently, providing drivers with a place to rest and take breaks. Four different types (A, B, C, and D) of services areas can be built on motorways. The type of service areas to be built in the Project has not yet been clarified.

In the scope of the Project, service areas will be built on each side of the Motorway, opposing to each other. Connection between two sites will be provided by suitable road structures (e.g. culvert, overpass, etc.). Parking areas for passenger vehicles and heavy vehicles will be separated. Service areas to be constructed of the Motorway are listed in Table III.16. An example layout for service areas is presented in Figure III.27.

Table III.16. List of Service Areas

Service Areas	Location on the Route (Motorway Km)
Service Area	Km 80+500
Service Area	Km 90+500
Service Area	Km 113+500
Service Area	Km 135+500

Figure III.27. Example Layout of a Service Area

III.2.7. Maintenance and Operation Centers

Maintenance centers should be constructed at least every 50-60 km on highways to ensure adequate level of service and regular maintenance and repair works. Additionally, primary maintenance centers will be established at intervals of every 120-150 km. Maintenance centers include offices, workshops, salt tanks, storage areas, garages, gas stations, management residences, dormitories and parking areas. The maintenance and operation center to be constructed for the Project is planned to be built at Km 64+500. It should be noted that the design works and approval process are ongoing; therefore, the specifications of these structures' may subject to change.

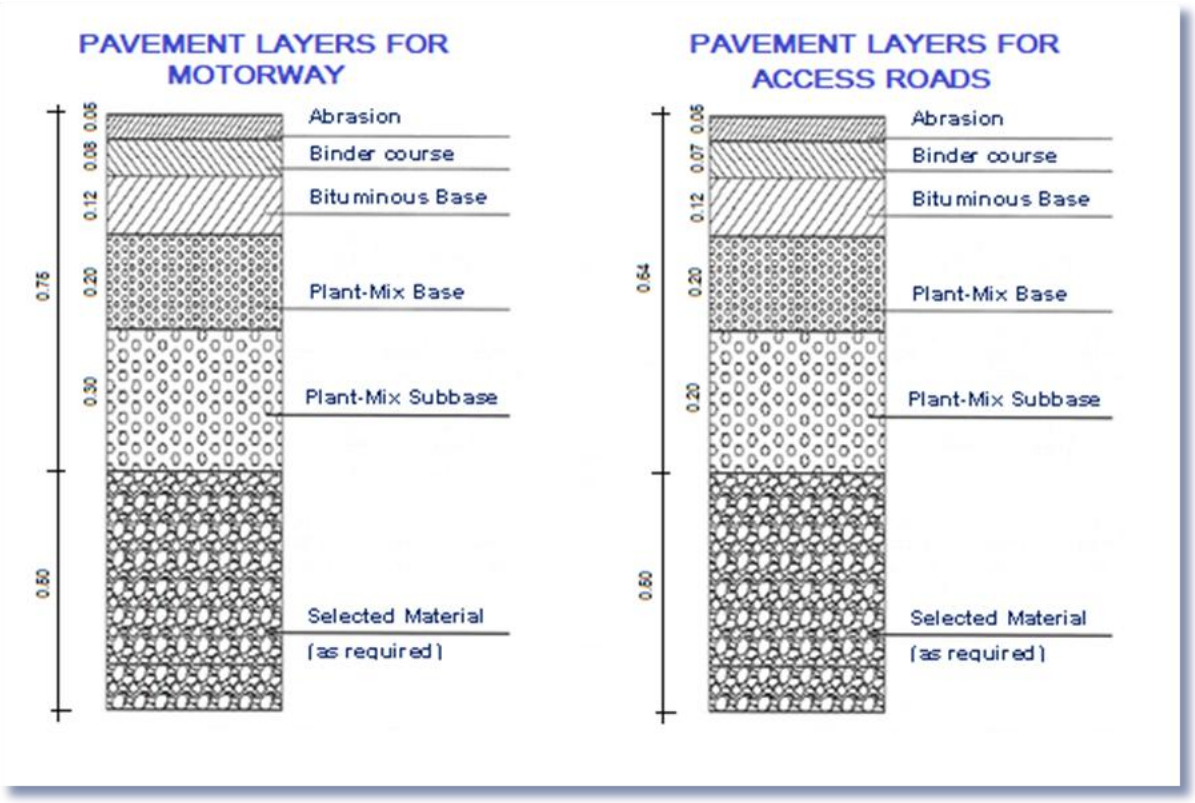
III.2.8. Pavement Structure

Layers of the road pavement and their thickness on the Motorway, access roads and other roads according to motorway specifications is listed in Table III.17 and demonstrated on the sketch given in Figure III.28. Mainly crushed and screened quarry materials will be used for the preparation of the pavement layers.

Table III.17. Pavement Layers and their Thickness

Layer	Thickness of Layers (cm)		
	Motorway	Access Roads	Ancillary Roads
Abrasion/Wearing Coarse*	5	5	5
Binder	8	7	7
Bituminous Base	12	12	10
Plant-Mix Base	20	20	20
Plant-Mix Subbase	30	20	20
TOTAL	**75**	**64**	**62**
Selected Material (CBR>=10)	50	50	50

**Abrasion Layer shall be of modified bituminous stone mastic asphalt*



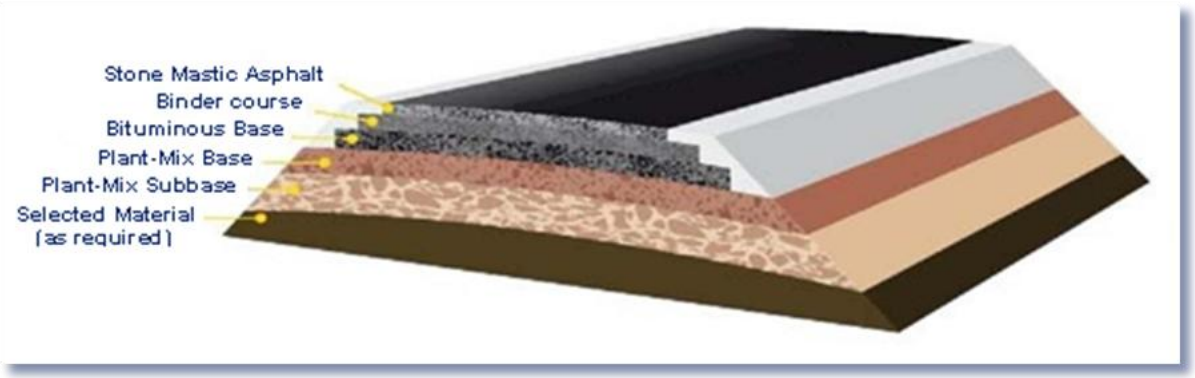


Figure III.28. Pavement Layers for the Motorway and Access Roads

III.3. Expropriation Corridor

In motorway projects, expropriation corridor is minimum 100 meters according to KGM standards. Where required, expropriation corridor is widened to cover the excavation and embankment areas and construction areas for the larger structures such as interchange areas, acceleration lanes, park and service areas, drainage ditches, etc. In the Project, expropriation corridor will be minimum 100 meters in accordance with the KGM's specifications, and it can be widened up to 350 meters depending on the topographical conditions and type and location of large Project components. The area to be allocated to the Motorway will be enclosed by suitable structures/materials (e.g. wire fence etc.).

III.4. Description of the Route

Based on the current design, the total length of the Motorway, which will be mostly 3 and partly 2 lane (3x2 and 2x2) divided road in each direction, is 117.8 kilometers including the main carriageway and access roads. A brief description of the Motorway is described in Table III.18 below with reference to the Motorway km(s).

Table III.18. Brief description of the Motorway

Km Chainage	Description
52+000 / 56+000	**Flat Agricultural Lands in Deniztepesi and Sarıabalı Neighborhoods** This section is located at the beginning of the Motorway route. The area consists mostly of flat agricultural lands, greenhouse areas, rural settlements and some residences of Deniztepesi Neighborhood. The southwest of this section is urbanized starting from a distance of approximately 6 km. Serik Junction near Deniztepesi and Sarıabalı neighborhoods are located in this section. Köprüçay also passes through the region. There are agricultural areas, greenhouse areas and some residences on the banks of Köprüçay in Sarıabalı Neighborhood.
56+000 / 66+000	**Sloping Forest Lands in Çakış, Sağırin and Taşağıl Neighborhoods** In this section of the Motorway route, there are sloping forest lands and agricultural lands on the slopes of the hills, as well as agricultural lands on the plains in Taşağıl Neighborhood.
66+000 / 70+500	**Flat Agricultural Lands in Hocalar and Gündoğdu Neighborhoods** In this section of the Motorway route, the entire area consists of flat agricultural lands. In Yavrudoğan Neighborhood, sloping forest lands on the slopes of the hills are noteworthy. Taşağıl Junction near Hocalar Neighborhood is located in this section.
70+500 / 88+000	**Flat Agricultural Lands in Yavrudogan, Kalemler, Yeniköy, Şişeler, Dolbazlar, Yukarıışıklar, Dikmen and Bucakşeyhler Neighborhoods** In this section of the Motorway route, the whole area consists of flat agricultural land, wooded areas on the slopes of hills and some houses belonging to neighborhoods. Manavgat Junction near Yukarıışıklar Neighborhood is located in this section. Along the connection road to Manavgat Junction, urban settlements are dense and there are also agricultural areas and greenhouse areas. Manavgat Stream also passes through the area.
88+000 / 90+500	**Sloping Forest Lands in Ulukapı Neighborhood** In this section of the Motorway route, there are sloping forest lands on the slopes of the hills and agricultural lands on the plains, as well as a few residential areas belonging to the Ulukapı Neighborhood.
90+500 / 100+000	**Flat Agricultural Lands in Aşağıışıklar, Demirciler, Karaöz, Aksaz, Hacıali, and Sülek Neighborhoods** In this section of the Motorway route, the entire area consists of flat agricultural land and forest areas on the slopes of hills. The Manavgat Interchange near Kalemler neighborhood is located in this section. There are a few greenhouses with larger areas in this section of the route.
100+000 / 104+000	**Sloping Forest Lands in Hacıisalı and Hacıobası Neighborhoods** In this section of the Motorway route, there are sloping forest lands on the slopes of the hills and agricultural lands on the plains. Manavgat East Junction near Hacıisalı Neighborhood is located in this section.
104+000 / 120+000	**Flat Agricultural Lands in Çavuşköy, Kadılar, Örenşehir, Yalçıdibi, Odaönü, Karakaya and Çakallar Neighborhoods** In this section of the Motorway route, the entire area consists of flat agricultural lands, greenhouse areas, wooded areas on the slopes of hills and residential areas belonging to neighborhoods. Alarahan Junction near Çakallar Neighborhood is located in this section.

Km Chainage	Description
120+000 / 125+500	**Sloping Forest Lands in İncekum and Avsallar Neighborhoods** In this part of the Motorway route, sloping forest lands are predominant on the slopes of the hills. There are also greenhouse areas on the plains of Avsallar Neighborhood.
125+500 / 136+000	**Sloping Forest Lands in Akdam, Türkler, Soğukpınar and Toslak Neighborhoods** In this section of the Motorway route, there are sloping forest lands on the slopes of the hills, as well as greenhouse areas on the plains of Akdam, Türkler, Soğukpınar and Toslak Neighborhoods, and scattered houses within these areas. The Konaklı Junction near the Soğukpınar Neighborhood is located in this section. Along the Konaklı Junction connection road, greenhouse areas are dense and residential areas are also located on the route.

The settlements located in the vicinity of the Motorway components are listed in Table III.19.

Table III.19. Settlements Located in The Vicinity of the Motorway Components

Districts	Neighborhoods	Nearest Approximate Motorway Km	Approximate Distance of the Settlement Center to Nearest Motorway Components (the nearest building) (m)	Direction with respect to Main Carriageway	Population (TURKSTAT 2024)

III.5. Workforce

The Project workforce will consist of personnel employed by the main contractor (direct workers) and by subcontractors (contracted workers). These personnel will be classified as site-based workers and office/administrative staff. Site-based workers refer to those directly engaged in field construction activities, whereas office/administrative staff include roles such as project managers, administrative staff, and drivers who are not physically involved in construction works.

During the peak construction phase, a total of approximately 2,300 personnel are expected to be employed, including 2,300 direct workers and 1,000 contracted workers. In the operation phase, the Project is anticipated to employ an estimated 250 personnel. These figures represent the maximum workforce requirements and are subject to variation depending on the pace and scale of construction and operational activities.

All labor-related environmental and social impacts assessed in this ESIA—such as accommodation needs, community health and safety risks, resource consumption, traffic load, and waste generation—have been calculated based on these estimated workforce numbers for both construction and operation phases. A detailed breakdown of the workforce distribution by project phase and employment type is provided in Table III.20**Error! Reference source not found.**.

Table III.20. Workforce Distribution by Project Phase and Employment Type

Project Phase	Workforce Type	Estimated Number of Workers
Construction Phase	Main Contractor Personnel	2,300
	Subcontractor Personnel	1,000
	Total Construction Workforce	3,300
Operation Phase	Operational Staff (All types)	250

** The number of personnel required will become clearer upon transition to the operational phase.*

Site personnel are mainly composed of engineers, technicians, foremen, topographers, operators, drivers, laboratory workers and unskilled workers. On the other hand, composition of office/administrative personnel generally includes Project Manager, Site Manager, office engineers, financial staff and other drivers.

In the operation phase, relevant personnel will work at the control, operation and maintenance centers and toll plazas. At each toll plaza, 4-5 personnel will provide services in shifts for the arrangement of cash payments. In addition, 4-5 personnel will work at each control center that will be established at the toll collection areas. Personnel to be employed at operation and maintenance centers will include white and blue-collar workers who will provide snow removal services and conduct maintenance, technical, repair and workshop operations.

In addition to the personnel to be employed at the toll collection areas and operation, control and maintenance works, the Project will create employment opportunities for local people at the service areas that will include restaurants, tea and coffee houses, shops, gas stations, kiosks, etc.

III.6. Construction Machinery

Number and distribution of construction machinery at the peak level of construction are provided in Table III.21.

Table III.21. List of Construction Machinery

Type of Machinery	Number of Machinery
Excavator	51
Grader	5
Bulldozer	14
Jumbo	12
Telehandler	12
Mobile Crane	20
Trans mixer	50
Shotcrete Machine	12
Loader	20
Mobile Concrete Pump	7
Fixed Concrete Pump	16
Water Truck	7
Drum Compactor	10
Asphalt Paver	12
Asphalt Distributor	2
Soil Compactor	14
Roller	10
Dump Truck	140
Rock Driller	12
Total	**426**

III.7. Materials to be used

Construction works require aggregates, concrete, steel, aluminum, cement, bitumen, cables, etc. Concrete will be required for the construction of bridges, retaining walls, culverts and other engineering structures. Aggregate material for concrete production will be sourced from licensed quarries. After extraction, the aggregate will be crushed, screened and washed as necessary. Concrete types/grades to be used in the Project will include the following:

- Precast prestressed beam concrete
- Post-tensioned prestressed beam concrete
- Reinforced Concrete
- Flat concrete

During the operation phase, road deicing activities will require the use of salt (NaCl), calcium chloride (CaCl2) and magnesium chloride (MgCl2). These materials will be used directly or mixed in appropriate proportions. The amount of chemicals to be used per m^2 of road surface will depend on road conditions (i.e. open roads before the onset of snowfall, snow-covered roads, and slippery icy roads) and air temperatures (between 0^0C and -12^0C).

In addition to the use of appropriate chemicals and materials such as concrete, cement, epoxy, repair mortar, rust removing chemicals, and hydrochloric acid for the repair and maintenance of engineering structures, the project will also require the use of various natural resources, including water and energy. These resources will be utilized during construction activities for purposes such as material processing, equipment operation, and site maintenance. Details including estimated quantities are given in the related chapters of this ESIA.

III.8. Traffic Projections

In accordance with the relevant provisions of the BOT contract, the guaranteed minimum traffic, measured in passenger vehicle equivalent (PCE) for the Project is set at 100.000 cars per day. Further traffic projection studies related to project feasibility are being conducted by the Project Sponsor. Upon completion, the relevant sections of the mentioned report will be incorporated into subsequent reports.

In review, we forecast that the total Average Annual Daily Traffic (AADT) on the Motorway will be c.25K passenger car equivalent units (pcu) in 2028, rising to c.60K pcu by 2040. The analysis assumes the motorway will become operational in 2028. Traffic projections are based on 2028 as the base year and consider four key future years: 2028, 2032, 2036, and 2040.

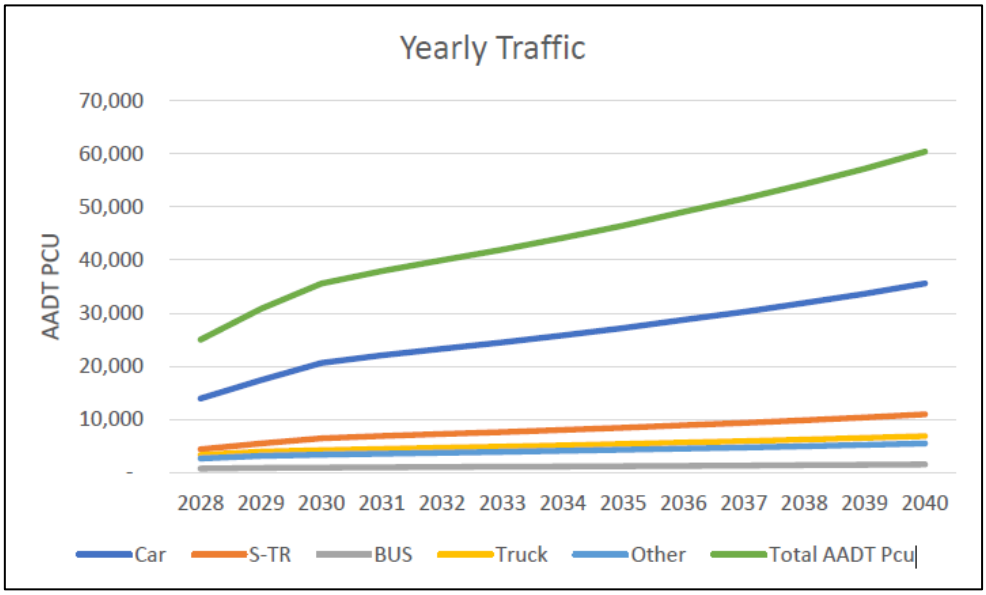

Figure III.29. Yearly Traffic of the Motorway

As can be observed in Figure III.29, light vehicle growth is projected to outpace truck growth, leading to a further decline in heavy-vehicle representation which is forecasted at 27% in 2028, and this is projected to fall to 22% in 2040.

The average capture rate at the beginning of the operation is projected to be approximately 44%. By 2040, the total traffic volume on the state road is expected to reach around 23,000 AADT (Annual Average Daily Traffic) in Passenger Car Units (PCU), while the motorway is anticipated to carry approximately 60,000 AADT PCU. This corresponds to an estimated average diversion rate of 72% by the end of the concession period. Detailed information on traffic projections and analysis is provided in the Traffic Due Diligence Report (Annex-12).

The land traffic in the construction phase will be generated by the machinery, equipment, material, and staff to be transported to the Project construction sites. During the construction phase especially an increase of trucks is expected. The transportation of heavy loads between burrow pits and quarries will be carried out by trucks. Most of these areas are right next to the construction area, except for Bademliyar and Saburlar Quarries, D-7 Storage Site (Two options). The routes are to be taken to and from this locations are as shown in Figure III.30 and Figure III.31, respectively.

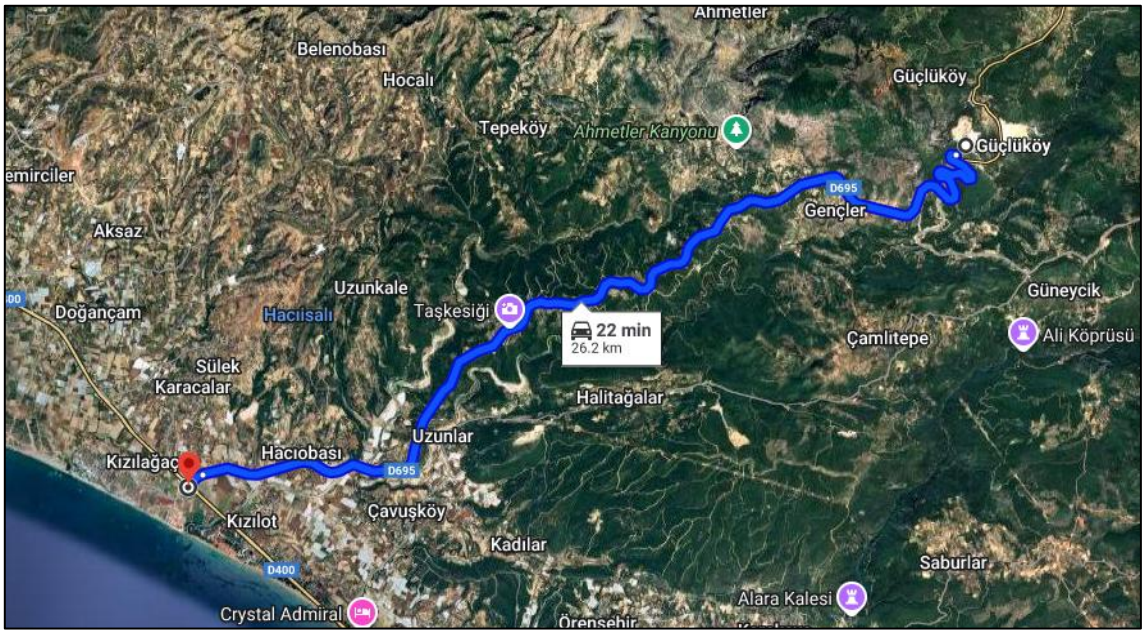

Figure III.30. D695 Route between Bademliyar Quarry and Motorway

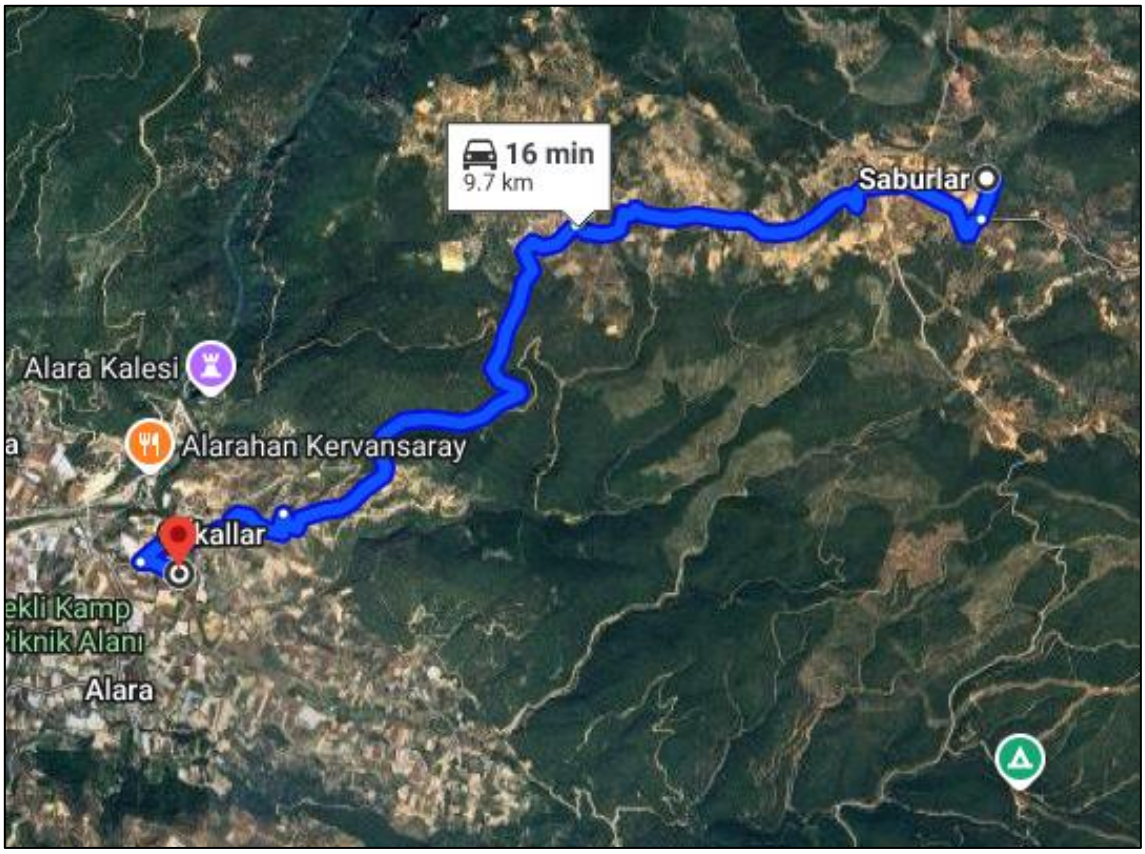

Figure III.31 Route between Saburlar Quarry and Motorway

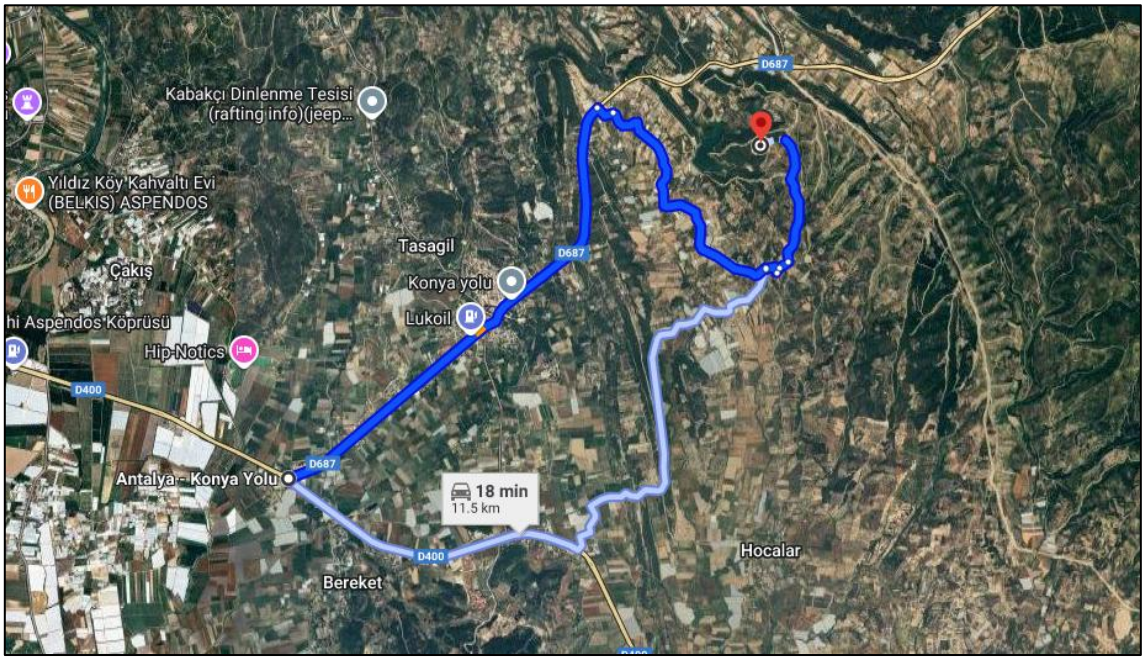

Figure III.32 Routes between D-7 and Motorway

Table III.22. Road Assessment for Transportation of Heavy Loads

Site	Route	Distance	Road Type
Bademliyar	D695	26.2 km	Single-lane road
Saburlar	Country Road	9.7 km	Single-lane road
D-7 (Option 1)	D687 → Country Road	12.2 km	Mostly double-lane road, partially single-lane road
D-7 (Option 2)	D400 → Country Road	11.5	Mostly single-lane road, partially double-lane road

During the construction phase, the Project's vehicles will not be on the road at the same time. However, in the worst-case scenario, it is assumed that all the vehicles will be on the road at the same time. It should be noted that since the assessment is based on the maximum traffic load increases at worst-case scenario, the increase in road traffic will be much lower than the values given in the table above in most of the time during a daily period.

As explained in the previous sections, these access roads to be within the scope of the Project already exist and may need extension / rehabilitation. Geometries of these roads were also assessed in terms of heavy goods vehicle movements during the route selection stage. Therefore, additional road construction is expected, with some extension or rehabilitation works as needed.

The anticipated impacts of increased traffic load during the construction phase are expected to manifest in several key areas. From an environmental perspective, the rise in traffic volume may result in notable consequences, particularly in terms of noise pollution and air emissions. Elevated noise levels along access roads leading to construction sites can disturb both local communities and wildlife, especially during early morning and late evening hours when ambient noise levels are typically lower.

In addition to environmental concerns, increased traffic may cause temporary road interruptions and closures due to ongoing construction activities. These disruptions can lead to traffic congestion and limited access for local residents and emergency services, creating both inconvenience and potential safety risks. Furthermore, the operation of heavy construction vehicles at high speeds introduces significant safety concerns for nearby communities. This is particularly critical in residential areas where pedestrian activity is prevalent, thereby increasing the likelihood of traffic-related accidents.

Lastly, the frequent use of existing roads by heavy vehicles may accelerate deterioration of road surfaces, leading to premature wear and tear. This degradation not only affects local infrastructure but also poses safety hazards for all road users, necessitating additional maintenance and repair efforts throughout the construction period.

III.9. Implementation Program

The Project is scheduled to be implemented over a six-year period, beginning in December 2023 and continuing through October 2028. The project comprises four main phases: contractual processes, administrative affairs, expropriation works, and highway construction works. The contractual phase extends from December 2023 to October 2024, followed by administrative procedures that are planned between October 2024 and October 2025. Expropriation works will be carried out from October 2024 through April 2026, overlapping with the construction phase, which spans from October 2024 to October 2028. A visual summary of the construction schedule is provided in Figure III.33, while further details on task breakdowns and timeframes are included in Annex-13.

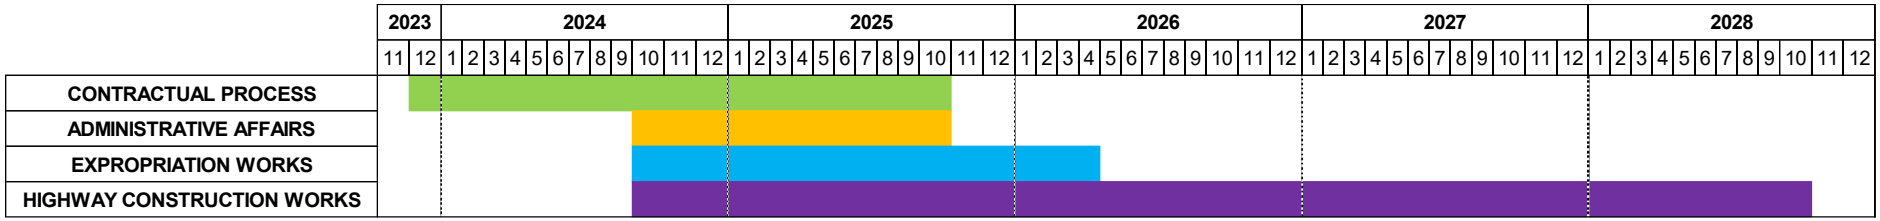

Figure III.33. Summary Construction Schedule of the Project

III.10. Project Cost and Incomes

As the Project will be implemented in the framework of a BOT model, financing, planning/design, building/construction, operation and full range of maintenance and repair works will be under the responsibility of the Project Sponsor for the contract duration. Finance structure of the Project as a BOT model is represented in Figure III.34.

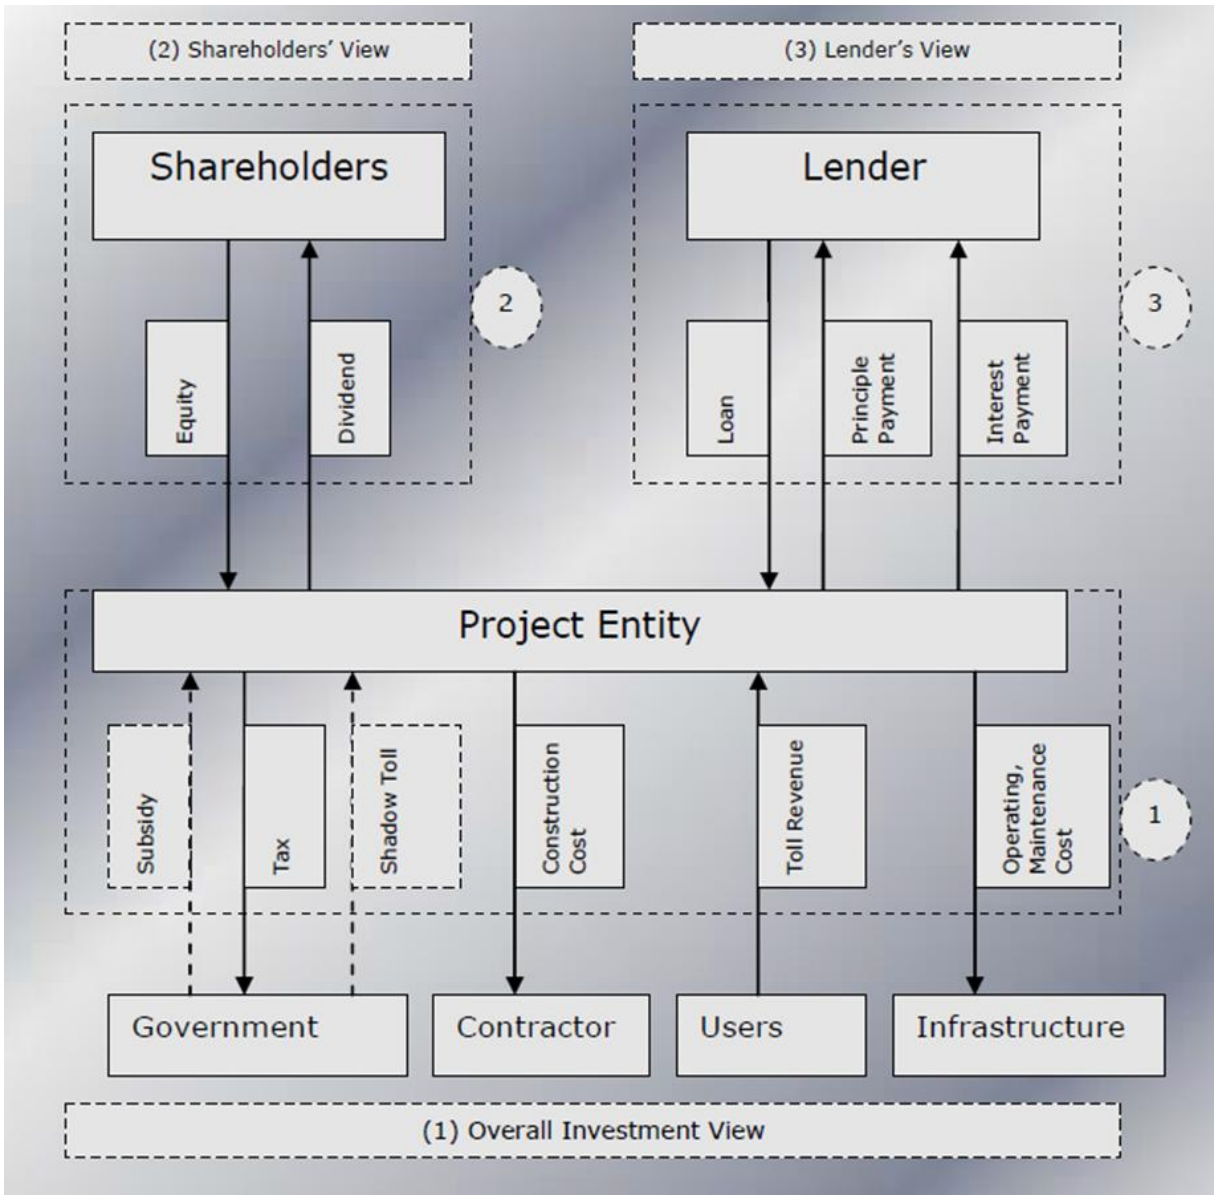

Figure III.34. Representation of the Finance Structure of BOT Projects (*Source: KGM, August 2010*)

The main cost items for the pre-operation and operation phases of the Project would include the following (KGM, June 2011):

- Expropriation costs;
- Construction costs for the Motorway components and access roads;
- Maintenance and repair costs during the operation phase (routine maintenance, winter maintenance, periodic maintenance in every 10 years);
- Other operation costs;
- Taxes;
- Reimbursement of credit principal and interest.

Construction costs will mainly include the costs for the expropriation, surveys, design, consulting services, earthworks, construction of engineering structures, bridges, overpasses, underpasses, etc.

Following the completion of the construction and commissioning of the Motorway, toll revenues will be collected from the road users by the Project Sponsor for the duration of the contract, specified as a total of 15 years, including 3 years for construction and 12 years for operation. If the toll revenues collected fall below the projected revenue for the minimum traffic guaranteed under the BOT contract (defined as 100.000 cars per day - see Section III.8), the difference will be compensated to the Project Sponsor. Additional revenue will be generated from the operation of the service areas.

IV. ESIA METHODOLOGY

The Antalya-Alanya Motorway Project is not considered in the scope of the EIA exemption decision and thus, full EIA report has been required for the Project in the context of the Turkish EIA Regulation. An EIA Report has been prepared and submitted to the MoEUCC and an "EIA Positive Decision" issued on August 17, 2018 (see Section II.2.1. for further explanation on the EIA positive decision).[1]

On the other hand, the Project Sponsor has secured a facility agreement with a group of lenders led by Deutsche Bank as Mandated Lead Arranger (MLA), which requires compliance with international environmental and social standards and guidelines throughout the implementation of the Project. In consideration of Equator Principles, World Bank policies and IFC's Sustainability Framework, the Project is evaluated to be likely to include activities and components that are to be effectively managed to avoid or minimize significant environmental and social impacts. In this respect, the Project would be classified as a ***Category A Project***, for which the borrower is responsible for preparing an EIA Report/full-scale ESIA. Similarly the EU's EIA Directive and the Turkish EIA Regulation, which has been harmonized with EU's EIA Directive also define the motorway construction projects as Annex I activities, for which an EIA is required. Similarly, an EIA Report has been prepared and an "EIA Positive Decision" had been issued for the Project which is the performance indicator that the project has gathered a local (national) environmental clearance. Consequently, a full-scale ESIA report will be prepared for the Project. The methodology to be followed in the ESIA study is described in the following sections.

In its simplest form, impact assessment is defined as the process of identifying the future consequences of a current or proposed action by the International Association for Impact Assessment. The environmental and social impact assessment (ESIA) study to be conducted for the Project will conform to both the requirements of the Turkish EIA Regulation as well as the international standards including Equator Principles (EPs) IV and IFC's Performance Standards on Environmental and Social Sustainability (including general and sector-specific EHS guidelines). IFC, in its Guidance Note 1 on the Assessment and Management of Environmental and Social Risks and Impacts, which was published in January 1, 2012 and updated in June 14, 2021, specifies the key process elements of an ESIA study as follows:

(i) Initial screening of the project and scoping of the assessment process;
(ii) Examination of alternatives;
(iii) Stakeholder identification (Focusing on those directly affected) and gathering ofenvironmental and social baseline data;
(iv) Impact identification, prediction and analysis;
(v) Generation of mitigation or management measures and actions;
(vi) Significance of impacts and evaluation of residual impacts;
(vii) Documentation of the assessment process (i.e. ESIA report).

Considering the procedural steps of the Turkish EIA Regulation (see II.2.1. for detailed explanation of the process) and based on IFC's approach that summarizes the international good practice for impact assessment, the systematic process to be conducted for the assessment of the Project's environmental and social impacts and development of mitigation measures and plans for the management of significant impacts is illustrated in Figure IV.1.

[1] *https://eced.csb.gov.tr/jsp/ek1/12532*

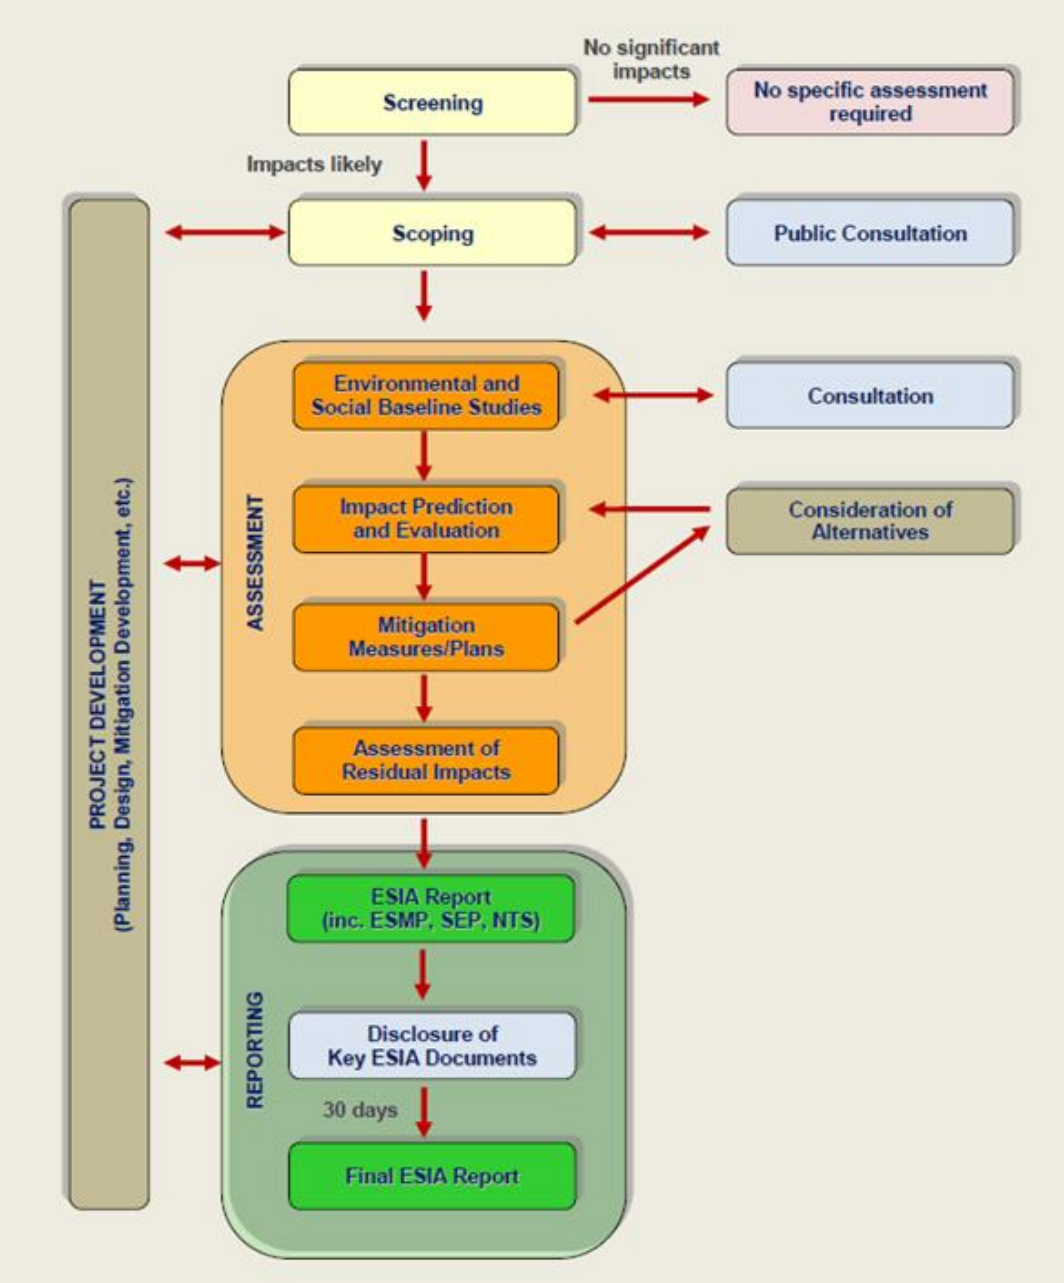

Figure IV.1. ESIA Process (adapted from IFC's Guide to Biodiversity for the Private Sector)

In the ESIA process, screening is used to make a rapid, high-level analysis to determine whether a full ESIA is necessary. The screening process conducted for the Project determined that the classification of the Project is "***Category A"***, thereby rendering the Project Sponsor responsible for preparing an EIA Report/full-scale ESIA.

Following the screening of the Project, scoping works have been conducted to identify the impacts likely to be significant and should become the main focus of the ESIA. A comprehensive baseline information assembly program was designed for the Project to establish a reference point from which any future changes associated with the Project can be assessed and provide information for subsequent monitoring. The baseline program relied on both desk-based studies to analyze readily

available information from governmental organizations, academic publications, internet resources, etc. as well as field surveys to gather site-specific environmental and social information.

Impact prediction and evaluation is the key of the ESIA and involves analyzing the impacts identified in the scoping and baseline work to determine their nature (adverse or beneficial, direct or indirect), temporal scale (permanent or temporary), spatial (local, regional, national, etc.) scale, reversibility (reversible or irreversible), magnitude (high, medium, low), likelihood (certain, likely, possible, unlikely etc.), extent and effect. Such detailed impact analysis requires professional judgment and input from relevant experts. Once the potential impacts are fully understood, it is necessary to judge the significance of each impact to determine whether it is acceptable, requires mitigation or is unacceptable. Cumulative impacts, which may result from multiple actions on valued receptors, have been separately assessed according to the IFC guidelines as a part of the study to the extent the level of readily available information allowed. As an iterative process, emerging findings of the assessments have been conveyed to design teams to develop mitigation plans for the Project, where feasible[2].

It should be noted that determining the significance of impacts is a complex and subjective process. A number of factors affect significance including the importance of resources at local, regional, national or international levels; whether the area is subject to formal or informal protection; the ecological values of potentially affected animal and plant species and habitats, and the value of the ecosystems as sources of food or livelihood for local communities[3].

Scoping of Environmental and Social Impacts

Scoping phase of an ESIA process serves for:

(i) Determination of impacts that are likely to be significant and should become the main focus of the upcoming impact assessment studies;
(ii) Identification of data availability and any gaps; and
(iii) Determination of the appropriate spatial and temporal scopes for the assessment and suggestion of suitable survey and research methodologies[4].

As with similar large infrastructure projects, the primary impacts of the Project that are to be assessed and suitably managed are anticipated to occur during the construction phase as a result of vegetation clearing, earth moving activities and civil works, extraction of construction materials (from quarries), involvement of large numbers of personnel and heavy machines/equipment, etc. The associated impacts would include changes in the land use and soils, habitat alteration and fragmentation, waste and wastewater generation within the construction corridor and construction sites (including campsites, quarries, and plants if any), emissions into air, noise generation, etc. In addition, acquisition of lands prior to the start of construction and the large-scale employment to be caused by the Project is likely to bring a variety of occupational health and safety issues and socio-economic impacts (i.e. physical or economic displacement) that require evaluation and management. For the Project, maximum duration of the construction phase has been specified in the related BOT Contract as 3 years. Thus, the construction phase impacts of the Project will be generally temporary, except the impacts on biodiversity and socio-economic environment.

During the operation phase, environmental and social impacts of the Project will be as a result of vehicle traffic on the Motorway route, road maintenance activities and surface water runoff through the impermeable road surfaces, etc. Employment opportunities will be provided, but at relatively lower

[2] *https://www.ifc.org/content/dam/ifc/doc/2021/20210614-ifc-ps-guidance-note-1-en.pdf*
[3] *IFC, 2016. A Guide to Biodiversity for the Private Sector: The Social and Environmental Impact Assessment Process*
[4] *IFC, 2016. A Guide to Biodiversity for the Private Sector: The Social and Environmental Impact Assessment Process*

levels when compared to construction phase. The associated impacts of the Motorway's operation are likely to include air emissions and noise generation along the Motorway route, use of hazardous materials, and waste and wastewater generation at service areas.

Besides the adverse environmental and social impacts, the Project is likely to bring several benefits including contribution to alleviation of existing traffic problems especially in Antalya and its surrounding provinces (Burdur, Muğla, Konya, Isparta, Karaman and Mersin), reduced travel times and increased transportation comfort, new employment opportunities during the construction phase and operations to be conducted at the service areas, maintenance works, etc.

Thus, the ESIA study focuses on the assessment and mitigation of the potential impacts on these environmental and social components. In addition, cumulative impacts on each environmental and social component are also assessed in the scope of ESIA study. It should be noted that this report including all the baseline information, scoping analyses and assessments and the maps presented in this Chapter, which has been prepared based on the current version of the route design, might be changed if a change order is submitted by the KGM in the future. Therefore, this ESIA Report is prepared based on the most current design available, until the Project has matured to the design freeze state.

As a consequence of the Project, the environmental and social components that are likely to interact with the construction and operation phase activities of the Project are listed below:

- Air Quality; and Climate Change
- Topography, Soils, and Geology;
- Water Resources;
- Noise and Vibration;
- Use of Resources and Waste Management;
- Protected Areas, Landscape, and Visual Environment;
- Ecology and Biodiversity;
- Cultural Heritage;
- Land Use and Property;
- Socio-economic Environment (including local and national conditions, transportation network and traffic loads);
- Labor and Working Conditions; and
- Community Health and Safety.

An interaction matrix is presented in Table IV.1 in order to outline the activities and/or impact factors that have potential to cause interaction of the Project with each related environmental and social component. This list identifies the activities that have a potential to cause environmental and social impacts and thus will be evaluated in the scope of ESIA studies. Based on this evaluation, mitigation measures will be developed for the activities that would be likely to cause significant environmental and social impacts.

Table IV.1. Interaction Potential Matrix for Scoping

Project Activities / Interaction Factors	Environmental and Social Components															
	Air Quality	Climate Change	Topography, Soils, and Geology	Water Resources	Noise and Vibration	Use of Resources and Waste Management	Landscape and Visual Environment	Protected Areas	Ecology and Biodiversity	Cultural Heritage (known and Undiscovered)	Land Use and Property	Local Social and Economic Conditions	National Economy	Transportation Network and Traffic Loads	Labor and Working Conditions	Community Health and Safety
Land Preparation and Construction Phase																
Land acquisition																
Veg. clearing, top soil stripping, cut/fill, construction																
Storage of excess excavated materials																
Construction materials extraction																
Construction material transportation																
Construction and operation of plants (mechanical, asphalt, cement)																
Hazardous materials use and waste generation																
Water use and domestic wastewater generation																
Rehabilitation works																
Employment of workforce																
Procurement of materials and services																
Operation Phase																
Operation of Motorway																
Road maintenance works																
Surface run-off																
Employment of workforce																
Operation of service areas, operation centers, etc.																

Source: Adapted from EIA Sectoral Guidance for Motorways/Toll Roads published by the former Ministry of Environment and Forestry in June 2009.

Color Code: *Interaction Potential* *Benefit Potential*

In the scope of the impact assessment, impacts will be categorized as land preparation and construction phase impacts and operation phase impacts. Additionally, residual impacts remaining after the mitigation measures will also be identified in the assessment. Activities such as vegetation removal, top soil stripping, soil improvement, land levelling, etc. will be considered as pre-construction activities, while the cut and fill operations, road construction, construction of road structures such as viaducts, overpasses, underpasses, culverts, buildings, service areas, completion of superstructures and finishing operations will be considered as the construction phase activities. Since the Project's construction will progress kilometer by kilometer and the pre-construction and construction activities will be conducted gradually in different sections, a strict distinction of the pre-construction and construction phases and the associated activities would not be practical thus impacts associated with both phases will be considered under the heading of "construction phase activities/impacts". The period after the completion of construction activities will be the operation phase of the Project. Due to the nature of the Project (a motorway project), no decommissioning has been assumed for the Project.

Study Area and Area of Influence (AoI)

Good ESIA practice suggests that the study area for ESIA is to be defined on a case-by-case basis reflecting the project and the surrounding environment over which significant effects can reasonably be thought to have the potential to occur both from that project in combination with other projects. The study area is recommended to be set for each individual topic[5].

The Area of Influence (AoI) for the Project will be determined individually for each different environmental and social component. In line with IFC PS 1, the AoI will encompass the following as appropriate:

- The area likely to be affected by: (i) the Project (e.g. Project sites, immediate airshed and watershed, or transport corridors) and the Project Sponsor's activities and facilities that are directly owned, operated or managed (including by contractors) and that are a component of the project (e.g. access roads, borrow and disposal areas construction camps); (ii) impacts from unplanned but predictable developments caused by the project that may occur later or at a different location; or (iii) indirect project impacts on biodiversity or on ecosystem services upon which Affected Communities' livelihoods are dependent.
- Associated facilities, which are facilities that are not funded as part of the project and that would not have been constructed or expanded if the project did not exist and without which the project would not be viable.
- Cumulative impacts that result from the incremental impact, on areas or resources used or directly impacted by the project, from other existing, planned or reasonably defined developments at the time the risks and impacts identification process is conducted.

The Social Area of Influence (SAoI), on the other hand, is defined by comprehensively evaluating key factors such as the socio-economic environment, social impacts (including population, demography, economy, employment, land acquisition, land use as well as vulnerable groups/peoples), labor influx, community health and safety, and cultural heritage. Thus, the Social Area of Influence (SAoI) of the Project is delineated as a 2-kilometer buffer zone (2 x 2 km buffer corridor both sides of the Motorway) surrounding the licensed area to encompass all potentially socially affected areas.

[5] *UK Highways Agency 205/08, Design Manual for Roads and Bridges*

In this respect, the Motorway including all of its components (i.e. interchanges, viaducts, service areas, etc.) as well as service roads, construction campsites (if any), quarries and plants (if any), borrow pits, storage areas, and temporary disposal sites have been considered in the ESIA to the extent the level of information allowed.

The ESIA study areas were determined to specifically cover the AoI and the SAoI. The Motorway width (37.5 m) and the minimum width of the expropriation corridor (55 m) were considered in determining these study areas. It should be noted that the expropriation corridor may extend up to a maximum 450 meters at the locations of interchanges, large embankment and cut sites, service areas, etc. Additionally, the quarries and storage areas that are located outside the expropriation corridor necessitated an expansion of the study area. The overall study area for the air quality and socio-economic environment studies were determined as 4 km (a 2 km buffer area on each side of the Motorway axis) to appropriately cover related risks and impacts. Lastly, within the scope of cumulative impact assessment (CIA) studies, an area of 5 km buffer zone around the Motorway route was determined to carry out the studies. In this respect, the proposed study areas for each environmental and social component are listed in Table IV.2. For any future location changes of the construction campsites, quarries and plants, and disposal sites as well as relevant Project components (i.e. interchanges), the study area will be expanded to cover the new AoI and SAoI during the ESIA studies as needed.

Table IV.2. Proposed Study Area for the Motorway

Environmental and Social Component	Study Area (m)*	Possible AoI / SAoI (m)
Air Quality	4,000	2,000
Topography, Soils, and Geology	400	100
Water Resources	1,000	500
Noise and Vibration	2,000	1,000
Landscape and Visual Environment	400	400
Ecology and Biodiversity***	400	100
Protected Areas	400	100
Cultural Heritage	400	100
Land Use and Property	400	100
Socio-economic Environment **	4,000	2,000
Community Health and Safety	2,000	1,000
Cumulative Impact Assessment	10,000	10,000

** Represents the total width. For example; a 400 m study area is composed of 2 x 200 m corridors (200 m located in the left side and 200 m located in the right side of the Motorway's axis, making a total of 400 m in total).*

*** It should be noted socio-economic environment, due to its nature, propound a distinction in the ESIA approach; thus the study area specified in the table for socio-economic environment should be considered as the minimum study area. Settlements, whose lands extend beyond the proposed study area, have also been included in the scoping assessments and will be included in the scope of ESIA assessments as well, wherever necessary.*

**** For biodiversity, the area of influence was initially defined based on the project's direct impacts. Nevertheless, the impact assessment and field surveys extended beyond the 400 m study area, and wider components of the project footprint were incorporated into the evaluation.*

The studies and measurements carried out within the scope of ESIA in accordance with the determined impact areas (AoI and SAoI) are summarized in Table IV.3 below (see Figure IV.2).

Table IV.3. Summary of the Studies and Measurements Planned/Conducted within the Scope of ESIA Studies

Subject		Date of the study	Number of Measurement Points
Preliminary Studies			
Reconnaissance Field Study		2-3 May 2024	-
Environmental Studies and Measurements			
Air Quality and Climate Change	Particulate Matter (PM_{10} & $PM_{2.5}$)	16 September-8 October 2024	21
	NO_2 & SO_2	21 September-21 October 2024	5
	VOC	17 October 2024	5

Assessing the Significance of Impacts

The significance of impacts is the key output of the environmental and social impact assessment process as the mitigation strategies/approaches of Projects are developed depending on the level of the significance.

The significance of impacts is a function of the value and sensitivity of the receptor or resource and the magnitude of the impact that causes a change in the conditions of the receptor or resource. Thus, assigning environmental and social value and sensitivity of the resources/receptors and estimation of the magnitude of impact are the initial steps to be completed to assess the significance of impacts. Once the value and sensitivity of the receptor/resource as well as the magnitude of impact, are determined, assessment of the significance is typically conducted through the use of impact categorization matrices.

For the evaluation of the significance of the impacts for construction and operation phases of the Project, the categorization matrix given in Table IV.4 will be used. This matrix allows the evaluation of the magnitude of impacts in combination with the sensitivity/value of receptors/resources. After the overall significance of impacts are categorized on the basis of this matrix, mitigation measures will be developed for the significant (i.e. high and/or medium) impacts, and the residual impacts could be evaluated after the implementation of the mitigation measures.

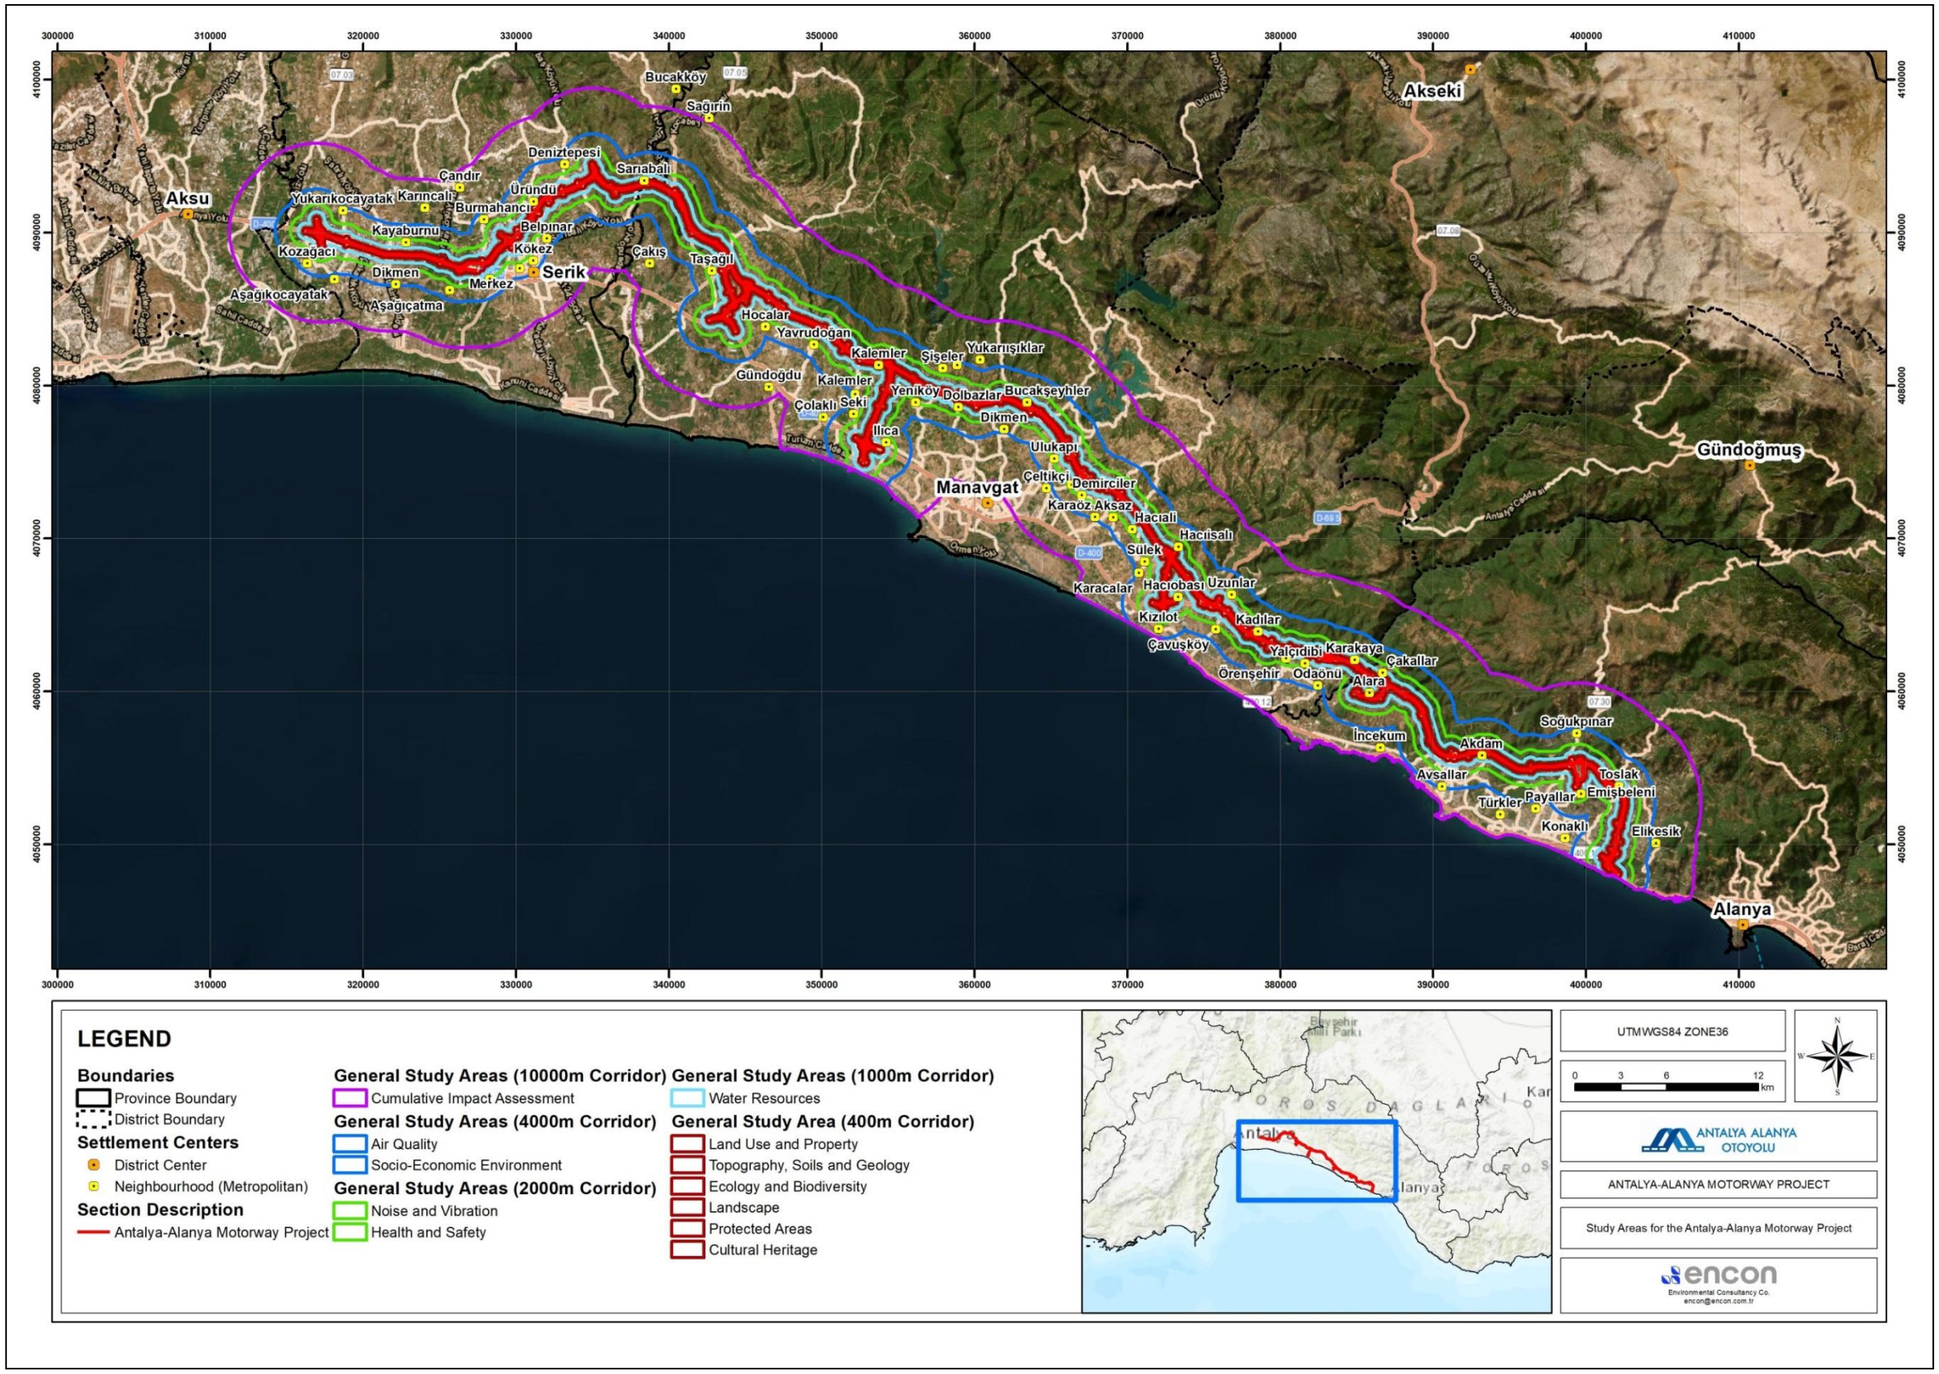

Figure IV.2. Study Areas for the Motorway Sections

Table IV.4. Impact Categorization Matrix*

		Sensitivity/Value of Receptor/Resource		
		High (3)	**Moderate (2)**	**Low (1)**
Magnitude of Impact	**Wide (A)**	High (A3)	High (A2)**	Medium (A1)
	Medium (B)	High (B3)	Medium (B2)	Low (B1)
	Restricted (C)	Medium (C3)	Low (C2)	Low (C1)

Impact Significance* **		
	High	Imperative to reduce impact significance by relevant mitigation before proceeding
	Medium	Significance is to be reduced to a lower category as long as it is feasible by taking relevant mitigation measures; if not possible can be proceeded by acceptance of associated risks
	Low	Acceptable to proceed without additional measures assurance of compliance with standards and safety criteria is assured

**Adapted from World Bank, December 2012.*

***It should be noted that the significance level represented by A2 was ranked as "medium" in the source document; but it has been modified to "high" in this assessment in order to be on the safe side and make a stricter assessment.*

****Adapted from L. Canter, 1993.*

The "magnitude" of the impacts given in this matrix represents their physical/geographical extent/range (in terms of area, length, etc.), duration (long-term, medium-term or short term), reversibility of the impact (short-term reversible, long-term reversible or irreversible), frequency (one-off, intermittent or continuous) and likelihood (unlikely, probable or certain) etc. The categorization of the magnitude (as restricted, medium, wide) would change for each resource (i.e. environmental media) under consideration. In this categorization, information on the total width of the Motorway and the extent of the expropriation corridor were also taken into consideration.

The structure of the impact categorization matrix to be used in the scope of the assessments entails categorization of value/sensitivity and magnitude in three levels. The "sensitivity/value" of receptor/resource given in the categorization matrix are defined individually for each type of receptor/resource depending on their value/importance for the community (i.e. cultural or economic) or wild life, existing quality, protection status that are identified based on the findings of the baseline studies (desk-based and field) and consultation to be done with local stakeholders. When a government-established threshold or national/international scientific literature is defined for a receptor/resource, it is prioritized during the sensitivity/value designation process. Otherwise, sensitivity/value designation is determined using professional judgement of the ESIA experts. Once the impacts are predicted and evaluated including judgment of significance, mitigation measures and plans could be developed, to eliminate or reduce adverse impacts. Typical descriptors that would be considered to describe specific sensitivity/value criteria for each individual environmental and/or social component under the relevant chapters of this ESIA Report are provided in Table IV.5.

Table IV.5. Typical Descriptors to be considered in Assigning Individual Value/Sensitivity Criteria

Value / Sensitivity Level	Typical Criteria Descriptors
High	High importance and rarity, international or national scale, and very limited potential for substitution.
Medium	Medium importance and rarity, regional scale, limited potential for substitution.
Low	Low importance and rarity, local scale.

Adapted from Highways Agency 205/08: Design Manual for Roads and Bridges.

Applying the matrix, the greater the environmental sensitivity/value of the receptor/resource, and the greater the overall magnitude of impact, the more significant the impact. For example, the consequences of a highly valued environmental resource or highly sensitive receptor suffering a major detrimental impact of high magnitude would be a very significant adverse impact[6].

In consideration of the individual factors, overall magnitudes of the impacts are determined for each impact separately. Magnitude factors and the typical descriptors that would be considered to estimate overall magnitude for impacts under the relevant chapters of this ESIA Report are provided in Table IV.6.

[6] *Highways Agency 205/08: Design Manual for Roads and Bridges*

Table IV.6. Impacts Magnitude Criteria

Magnitude Factors						Typical Criteria Descriptors for Overall Magnitude *		
Type	**Geographic Extent**	**Duration**	**Reversibility**	**Frequency**	**Magnitude**	**Overall Magnitude Level**	**Adverse/Negative**	**Beneficial/Positive**
Beneficial / Positive	**Restricted** (within the expropriation corridor; < 200 m at each side of the Motorway axis)	**Short** (less than 1 year)	**Short term reversible** (within 3 years)	**One-off / Occasional**	**Low** (e.g. amount of land use to be affected is less than 5% of the total amount of land use within the impact area)	**Minor**	**Some measurable change in attributes, quality or vulnerability; minor loss of, or alteration to, one (maybe more) key characteristics, features or elements**	**Minor benefit to, or addition of, one (maybe more) key characteristics, features or elements; some beneficial impact on attribute or a reduced risk of negative impact occurring**
Neutral	**Local** (200 to 1,000 m at each side of the Motorway axis)	**Medium** (1 - 3 years)	**Long term reversible** (3 - 15 years)	**Intermittent**	**Medium** (e.g. amount of land use to be affected is less than 10% of the total amount of land use within the impact area)	**Moderate**	**Loss of resource, but not adversely affecting the integrity; partial loss of / damage to key characteristics, features or elements**	**Benefit to, or addition of, key characteristics, features or elements; improvement of attribute quality**
Adverse / Negative	**Wide** (> 1,000 m at each side of the Motorway axis)	**Long** (more than 3 years)	**Irreversible**	**Recurrent / Continuous**	**High** (e.g. amount of land use to be affected is more than 10% of the total amount of land use within the impact area)	**Major**	**Loss of resource and / or quality and integrity of resource; severe damage to key characteristics, features or elements**	**Large scale or major improvement of resource quality; extensive restoration or enhancement; major improvement of attribute quality**

** Adapted from Highways Agency 205/08: Design Manual for Roads and Bridges.*

Mitigation and Residual Impacts

Following the determination and assessment of impacts, which includes valuing their significance, mitigation measures and plans are developed to eliminate or reduce adverse impacts and enhance benefits. The mitigation hierarchy given in Figure IV.3 will be followed at this stage of the ESIA whenever technically and financially possible. In this hierarchy, avoidance is considered the most acceptable form of mitigation. It may require changes to be made on the Project's design or location that would be done wherever technically and financially feasible. Minimization and mitigation through environmental and social measures/treatments/design is aimed where avoidance is not a possible option. Compensation/offset for residual risks and impacts is considered to be the last option in this hierarchy where avoidance or minimization and/or mitigation measures are not available. This option does not eliminate the identified adverse risks and impacts, but they seek to offset it with an (at least) comparable positive one.

1. Avoidance of impacts altogether.
2. Minimization/reduction of impacts where unavoidable.
3. Mitigation of impacts (e.g. restoration of habitats to their original state, relocation of affected species and habitats, etc.).
4. Compensation for any residual, unavoidable damage.

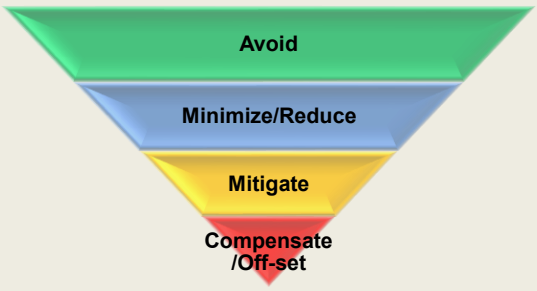

Figure IV.3. Mitigation Hierarchy to be Adopted

Within this ESIA, impact categorization and significance have been evaluated with reference to definitive standards, accepted/published criteria and legislation, where available. Where it has not been possible to quantify impacts, qualitative assessments have been carried out, based on expert knowledge, GIIP and professional judgement. Quantitative methods predict measurable changes as a result of the Project and rely on accurately measuring baseline conditions to make accurate predictions/estimations regarding the potential impacts. Qualitative assessment methods rely on expert judgement and experience.

While it is important to identify the initial significant impacts associated with the Project, the key focus of the impact assessment has been to define the significance of residual impacts and effects following application and/or consideration of mitigation measures. A residual impact is one which continues to be present following the application of avoidance and/or mitigation measures. In this regard, a summary table is provided in the final section of each chapter to indicate the potential significance of impacts first in the absence and then in the presence of mitigation to assist in demonstrating the anticipated effectiveness of proposed mitigation measures and assign the significance of residual impacts.

Cumulative impacts have been separately assessed in Chapter 17 ("Cumulative Impact Assessment"). The methodology for the cumulative impact assessment (CIA) is also provided in the same chapter.

V. LAND USE AND PROPERTY

This Chapter identifies the existing land use characteristics and ownership properties along the Antalya-Alanya Motorway route and assesses the potential impacts of the Antalya-Alanya Motorway Project on these aspects. Measures proposed for the mitigation of the potential impacts and the residual impacts are also described in this Chapter. Potential socio-economic impacts on local communities and/or owners/users of the affected lands (e.g. physical displacement, economic displacement, etc.) associated with the changes in the existing land use characteristics are covered in Chapter 14 ("Socio-economic Environment").

V.1. Assessment Methodology and Data Sources

The study area for the land use analyses has been determined based on the width of the expropriation corridor, which will have a width of minimum 55 meters in accordance with motorway standards and may expand up to 450 meters depending on topographical conditions and associated cut and fill plans. Accordingly, the GIS analyses have been conducted for a corridor having a width of 400 meters (in addition to the Motorway width, around 200 meters in each side), which covers the maximum expropriation corridor.

The land use characteristics for each section of the Motorway have been analyzed using "Coordination of Information on the Environment (CORINE) Land Cover" (2018) database, "Identification and Improvement of Problematic Agricultural Lands Project (STATİP)" (2015) database and Former Turkish General Directorate for Rural Services (GDRS) database for Antalya, all with the aid of GIS tools. The results of the land use analyses are presented in

Table V.3 and Table V.4 according to CORINE (2018), STATIP (2015) and GDRS, respectively. Comparison of the results of the land use analyses is also given in Table V.8.

Tunnels and viaducts have been incorporated into the Project design primarily to address geotechnical and topographic challenges along the route, while also aiming to avoid or minimize impacts on environmental and social receptors such as f orested areas, water bodies, residential zones, and cultural heritage sites. Due to their structural characteristics, these engineering solutions are expected to result in no or minimal physical impact on existing land use and ownership patterns, with potential effects limited to the footprints of tunnel portals and viaduct foundations. Therefore, in the context of the land use assessment, these structures are considered to have negligible influence on land use characteristics within the corridor.

Since land use along the sections above tunnels (excluding cut-and-cover tunnels) will remain unchanged—for instance, forestlands located above the tunnel alignment will be fully preserved—and the impact of viaducts will be limited to their foundation points, which represent a negligible area relative to the total length of the structures, these portions of the corridor have not been included in the land use study area in order to prevent potential misinterpretation of land take and impact.

The study area (400 m) itself does not directly represent the amount of land to be affected by the Project, as it has been identified more than the maximum width of the expropriation corridor, which is 450 meters. Accordingly, to make more accurate judgments on the amount of land to be affected, as the next step, expropriation plans prepared for the Antalya-Alanya Motorway Project and land use (i.e. forestry) permits obtained/to be obtained for the lands to be used will also be analyzed to characterize the land use patterns and ownership information. To characterize the forestry features within the study corridor, relevant Forest Management Plans and Forest Stand Maps will be analyzed with the aid of GIS. For the construction facilities that are located on registered lands, database of the General Directorate of Land Registry and Cadastre and land use permits will also be used. The result of the

analyses to be conducted will be presented in tabular formats and land use maps will also be produced for visual representation.

The data sources to be used in this scope are listed below:

- Coordination of Information on the Environment (CORINE) Land Cover" (2018)
- Identification and Improvement of Problematic Agricultural Lands Project (STATİP) (2015)
- Land Use Database of the former Turkish General Directorate for Rural Services (GDRS)
- Database of the General Directorate of Land Registry and Cadastre
- Forest Management Plans and relevant Forest Stand Maps (official data from the General Directorate of Forestry)
- 1/100.000 scale Environmental Master Plan of Antalya-Burdur-Isparta Planning Region
- Expropriation Plans prepared for the Antalya-Alanya Motorway Project
- Land use permits/easement rights obtained by KGM in the scope of the Project.

Significance Criteria

The significance criteria for the impacts on land use and property will be determined, as high, medium or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter 4 ("ESIA Methodology") will be used for the determination of the magnitude of impact on the land use components, while sensitivity/value criteria to be used in the scope of impact assessment is summarized in Table V.1. Detailed explanation of the sensitivity components for each resource/receptor is provided in the following section: Baseline Conditions.

Table V.1. Criteria for Sensitivity/Value of Resource/Receptor

Resource/Receptor	Sensitivity/Value Level		
	High (3)	Moderate (2)	Low (1)
Forest lands	Forests having ecological functions according to Forestry Management Plans	Forests having social and cultural funcitons according to Forestry Management Plans	Forests having economic function according to Forestry Management Plans
Agricultural areas	Lands having land use capability of Class I-II according to GDRS Database (agricultural lands suitable for agricultural soil cultivation)	Lands having land use capability of Class III-IV according to GDRS Database (agricultural lands not suitable for soil cultivation)	Lands having land use capability of Class V-VIII according to GDRS Database (Non-arable lands)
Pasturelands	Lands having land use capability of Class I-V according to GDRS Database	Lands having land use capability of Class VI according to GDRS Database	Lands having land use capability of Class VII-VIII according to GDRS Database

V.2. Baseline Conditions

Further evaluation of the baseline land use characteristics according to different information sources is provided below.

V.2.1. Land Use Characteristics within the Study Area

V.2.1.1. Land Use Characteristics according to CORINE Database

The CORINE program was initiated in the European Union in 1985 (http://www.eea.europa.eu/). As part of this initiative, the land cover project was developed to provide consistent, localized geographical information on land cover across the member states of the European Community.

The studies in the scope of CORINE program in Türkiye were started by the former State Statistical Institute (currently acting as Turkish Statistical Institute-TurkStat) in 2001. The former Ministry of Food, Agriculture and Livestock (now the Ministry of Agriculture and Forestry) were then involved. As a result of the studies, CORINE 1990, 2000, 2006, 2012, 2018 land cover maps and changed databases between 1990-2000, 2000-2006, 2006-2012, 2012-2018 were created and submitted to the European Environment Agency and as of now, they have been merged with European land cover maps and have taken their place in the whole European map1. The overall land cover classification of CORINE database, which provides a conceptual framework for understanding the different types of land cover, is listed in **Error! Reference source not found.**.

Table V.2. General Land Cover Classification of the CORINE Database

Level 1	Level 2	Level 3	Definition
1. Artificial surfaces	1.1. Urban Fabric	1.1.1. Continuous Urban Fabric	Most of the land is covered by buildings, roads and artificially surfaced area covering almost all the ground. Non-linear areas of vegetation and bare soil are exceptional.
		1.1.2. Discontinuous urban fabric	Most of the land is covered by structures. Buildings, roads and artificially surfaced areas associated with vegetated areas and bare soil, which occupy discontinuous but significant surfaces.
	1.2 Industrial, commercial and transport	1.2.1. Industrial or commercial units	Areas with artificial surfaces (asphalt, concrete, stabilized) consisting of buildings and/or green areas without vegetation.
		1.2.2. Road and rail networks and associated land	Motorways, railways, including associated installations (stations, platforms, embankments). Minimum width to include: 100 m.
		1.2.3. Port areas	Infrastructure of port areas, including quays, dockyards and marinas.
		1.2.4. Airports	Airport installations: runways, buildings and associated land.
	1.3. Mine, dump and construction sites	1.3.1. Mineral extraction sites	Areas with open-pit extraction of industrial minerals (sandpits, quarries) or other minerals (opencast mines). Includes flooded gravel pits, except for river-bed extraction.
		1.3.2. Dump Sites	Landfill or mine dump sites, industrial or public.
		1.3.3. Construction Sites	Spaces under construction development, soil or bedrock excavations, earthworks.
	1.4. Artificial, non-agricultural vegetated	1.4.1. Green Urban Areas	Areas with vegetation within urban fabric. Includes parks and cemeteries with vegetation.

[1] *https://corine.tarimorman.gov.tr/corineportal/turkiyecalismalar.html*

Level 1	Level 2	Level 3	Definition
	areas	1.4.2. Sport and Leisure Facilities	Camping grounds, sports grounds, leisure parks, golf courses, racecourses, etc. Includes formal parks not surrounded by urban zones.
2. Agricultural areas	2.1. Arable Land	2.1.1. Non-irrigated arable land	Cultivated areas regularly ploughed and generally under a rotation system.
		2.1.2. Permanently irrigated land	Crops irrigated permanently and periodically, using a permanent infrastructure (irrigation channels, drainage network). Most of these crops could not be cultivated without an artificial water supply. Does not include sporadically irrigated land.
		2.1.3. Rice fields	Land developed for rice cultivation. Flat surfaces with irrigation channels. Surfaces regularly flooded.
	2.2. Permanent crops	2.2.1. Vineyards	Areas planted with vines.
		2.2.2. Fruit trees and berry plantations	Parcels planted with fruit trees or shrubs: single or mixed fruit species, fruit trees associated with permanently grassed surfaces. Includes chestnut and walnut groves.
		2.2.3. Olive groves	Areas planted with olive trees, including mixed occurrence of olive trees and vines on the same parcel.
	2.3. Pastures	2.3.1. Pasture Areas	Dense, predominantly graminoid grass cover, of floral composition, not under a rotation system. Mainly used for grazing, but the fodder may be harvested mechanically. Includes areas with hedges (bocage).
	2.4. Heterogeneous agricultural areas	2.4.1. Annual products available together with permanent products	Non-permanent crops (arable lands or pasture) together with permanent crops on the same parcel.
		2.4.2. Complex cultivation	Juxtaposition of small parcels of diverse annual crops, pasture and/or permanent crops.
		2.4.3. Land principally occupied by agriculture, with significant areas of natural vegetation	Areas principally occupied by agriculture, interspersed with significant natural areas.
		2.4.4. Agro-forestry areas	Annual crops or grazing land under the wooded cover of forestry species.
3. Forests and semi-natural areas	3.1 Forests	3.1.1 Broad-leaved forest	Vegetation formation composed principally of trees, including shrub and bush understories, where broad- leaved species predominate.
		3.1.2 Coniferous forest	Vegetation formation composed principally of trees, including shrub and bush understories, where coniferous species predominate.
		3.1.3 Mixed forest	Vegetation formation composed principally of trees, including shrub and bush understories, where broad- leaved and coniferous species co-dominate.
	3.2. Shrub and/or herbaceous vegetation	3.2.1. Natural grassland	Low productivity grassland. Often situated in areas of rough uneven ground. Frequently includes rocky areas, briars, and heathland.

Level 1	Level 2	Level 3	Definition
	associations	3.2.2. Moors and heathland	Vegetation with low and closed cover, dominated by bushes, shrubs and herbaceous plants (heath, briars, broom, gorse, laburnum, etc.).
		3.2.3. Sclerophyllous vegetation	Bushy sclerophyllous vegetation. Includes *maquis and garrige.* *Maquis:* a dense vegetation association composed of numerous shrubs associated with siliceous soils in the Mediterranean environment. *Garrigue:* discontinuous bushy associations of Mediterranean calcareous plateaus. Generally composed of kermes oak, arbutus, lavender, thyme, cistus, etc. May include a few isolated trees.
		3.2.4. Transitional woodland/shrub	Bushy or herbaceous vegetation with scattered trees. Can represent either woodland degradation or forest regeneration/colonization.
	3.3. Open spaces with little or no vegetation	3.3.1. Beaches, dunes, and sand plains	Beaches, dunes and expanses of sand or pebbles in coastal or continental, including beds of stream channels with torrential regime.
		3.3.2. Bare rock	Scree, cliffs, rocks and outcrops.
		3.3.3. Sparsely vegetated areas	Includes steppes, tundra and badlands. Scattered high-attitude vegetation.
		3.3.4. Burnt areas	Areas affected by recent fires, still mainly black.
		3.3.5. Glaciers and perpetual snow	Land covered by glaciers or permanent snowfields.
4. Wetlands	4.1. Inland wetlands	4.1.1. Inland marshes	Low-lying land usually flooded in winter, and more or less saturated by water all year round.
		4.1.2. Peatbogs	Peatland consisting mainly of decomposed moss and vegetable matter. May or may not be exploited.
	4.2. Coastal wetlands	4.2.1. Salt marshes	Vegetated low-lying areas, above the high-tide line, susceptible to flooding by sea water. Often in the process of filling in, gradually being colonized by halophilic plants.
		4.2.2. Salines	Salt-pans, active or in the process of. Sections of the salt marsh exploited for the production of salt by evaporation. They are clearly distinguishable from the rest of the marsh by their segmentation and embankment systems.
		4.2.3 Intertidal flats	Generally unvegetated expanses of mud, sand or rock lying between high and low water-marks. On contour on maps.
5. Water bodies	5.1. Inland waters	5.1.1. Water courses	Natural or artificial water-courses serving as water drainage channels. Includes canals. Minimum width to include: 100 m
		5.1.2. Water bodies	Natural or artificial stretches of water.
	5.2. Marine waters	5.2.1. Coastal lagoons	Unvegetated stretches of salt or brackish waters separated from the sea by a tongue of land or other similar topography. These water bodies can be connected with the sea at limited points, either permanently or for parts of the year only.
		5.2.2. Estuaries	The mouth of a river within which the tide ebbs and flows.

Level 1	Level 2	Level 3	Definition
		5.2.3. Sea and ocean	Zone seaward of the lowest tide limit.

Land use characteristics within the study corridor were analyzed according to CORINE 2018 database and the results of the analysis are presented in **Error! Reference source not found.**. In addition, Maps demonstrating the land-use character of the Project sections, five (5) sections in total, according to CORINE 2018 database are presented in from
Figure V.1 to Figure V.5 respectively.

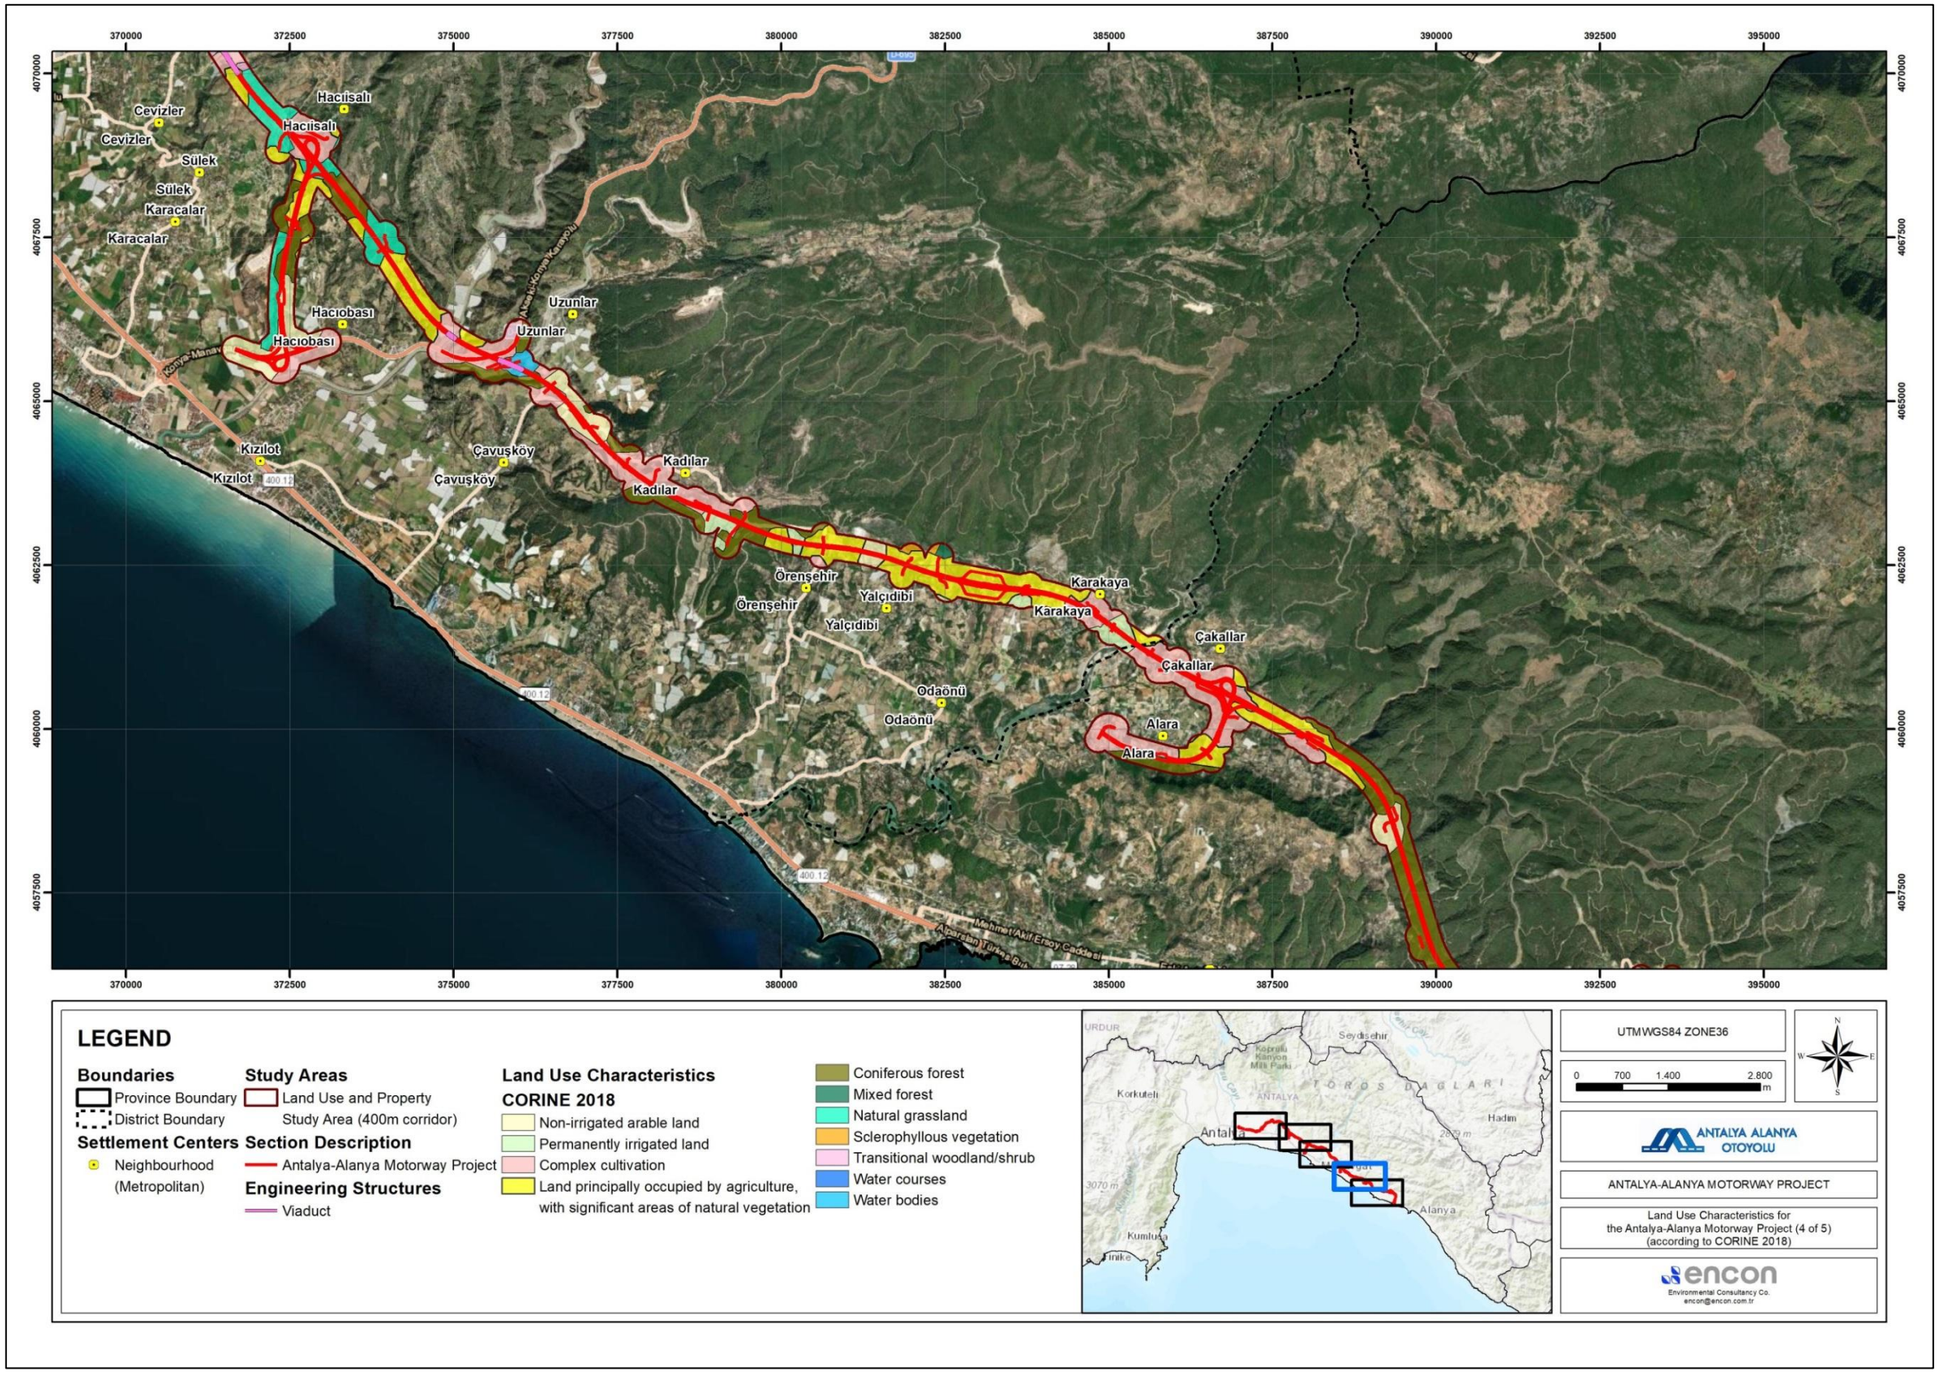

Figure V.4. Map of Land Use Characteristics for the Project according to the CORINE 2018 (4 of 5)

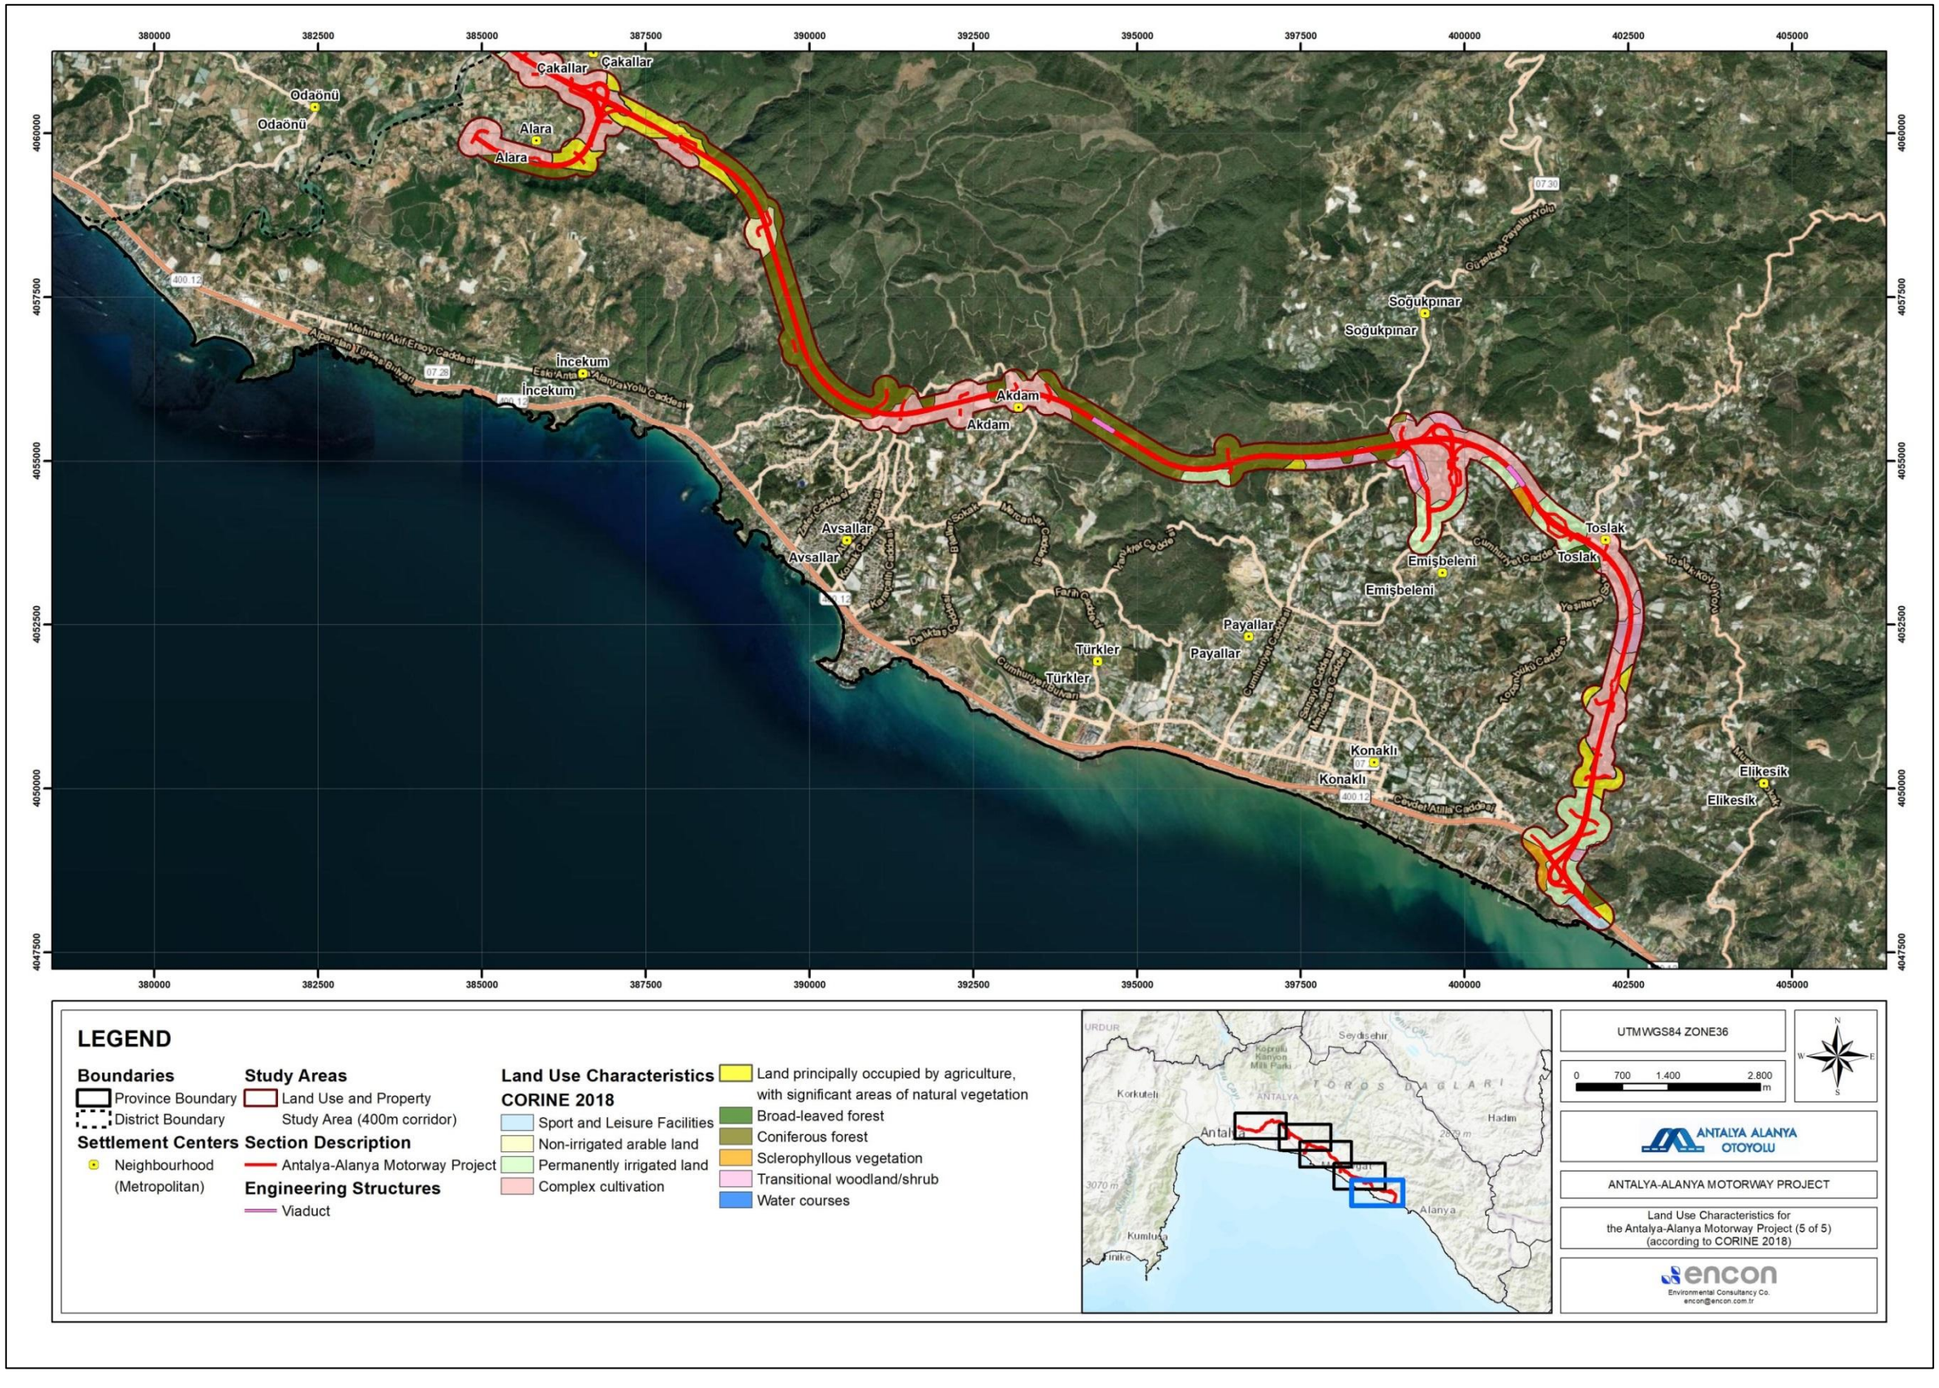

Figure V.5. Map of Land Use Characteristics for the Project according to the CORINE 2018 (5 of 5)

The land use characteristics along the Antalya–Alanya Motorway route (covering the maximum expropriation corridor of 450 meters) have been analyzed using the CORINE Land Cover (2018) classification system. The total study area is 6,856.13 hectares. The key findings of the analyses done based on CORINE database for the total study corridor of 6,856.13 hectares is summarized below.

The analysis reveals that the predominant land use type within the corridor is agricultural land, which accounts for 76.06% of the total area (5,214.46 ha). Within this category, heterogeneous agricultural areas are the most widespread, covering 53.04% of the study area (3,636.23 ha), followed by arable land at 20.56% (1,409.85 ha) and permanent crops at 2.46% (168.38 ha).

Forest and semi-natural areas represent the second-largest land use category, comprising 22.68% of the corridor (1,554.82 ha) consisting of forests and shrub and/or herbaceous vegetation associations. The most dominant sub-category within this classification is coniferous forest (711.44 ha; 10.38%) followed by transitional woodland-shrub areas (626.73 ha; 9.14%).

Artificial surfaces make up a very small proportion of the corridor, amounting to just 0.69% (47.58 ha), primarily consisting of industrial, commercial, and transport units and sport and leisure facilities.

Water bodies occupy a negligible portion of the study area, covering only 0.57% (39.27 ha), mainly in the form of water courses and water bodies.

This distribution highlights that the project corridor is largely dominated by agricultural and forested landscapes, with minimal presence of urban or industrialized land uses. A significant portion of the study area consists of natural and semi-natural land types, including forests, shrublands, and heterogeneous agricultural areas.

V.2.1.2. Land Use Characteristics according to Identification and Improvement of Problematic Agricultural Lands Project (STATİP)

STATIP (“Identification and Improvement of Problematic Agricultural Lands Project”) aims to identify and classify land and soil resources in accordance with scientific principles within the framework of the Law No. 5403 on Soil Conservation and Land Use. In 2002, it was initiated by the General Directorate for the Development of Agricultural Production and was later carried out by the Agricultural Basins Branch Directorate and currently by the Department of Geographical Information Systems of the General Directorate of Agricultural Reform. It digitized village boundaries and agricultural lands using 1/25,000 scale topographic maps and satellite images, transferred the data to GIS environment and shared it with public institutions. Its objectives include providing rapid access to land information, supporting agricultural production and planning, identifying land uses in line with EU standards and providing up-to-date data for greenhouse gas emission calculations.

Land use characteristics within the study corridor were analyzed according to STATIP 2015 database and the results of the analysis are presented in Table V.4. In addition, maps showing the land use characteristics of the Project sections, which consist of five (5) sections in total, according to STATIP 2015 database are presented in from Figure V.6 to Figure V.10 respectively.

Table V.4. Land Use Characteristics along the Project Route according to STATİP 2015

Level 1	Level 2	Level 3	STATIP CODE	Antalya-Alanya Motorway Project			Level 1 Total Area (ha)		Level 2 Total Area (ha)		Level 3 Total Area (ha)

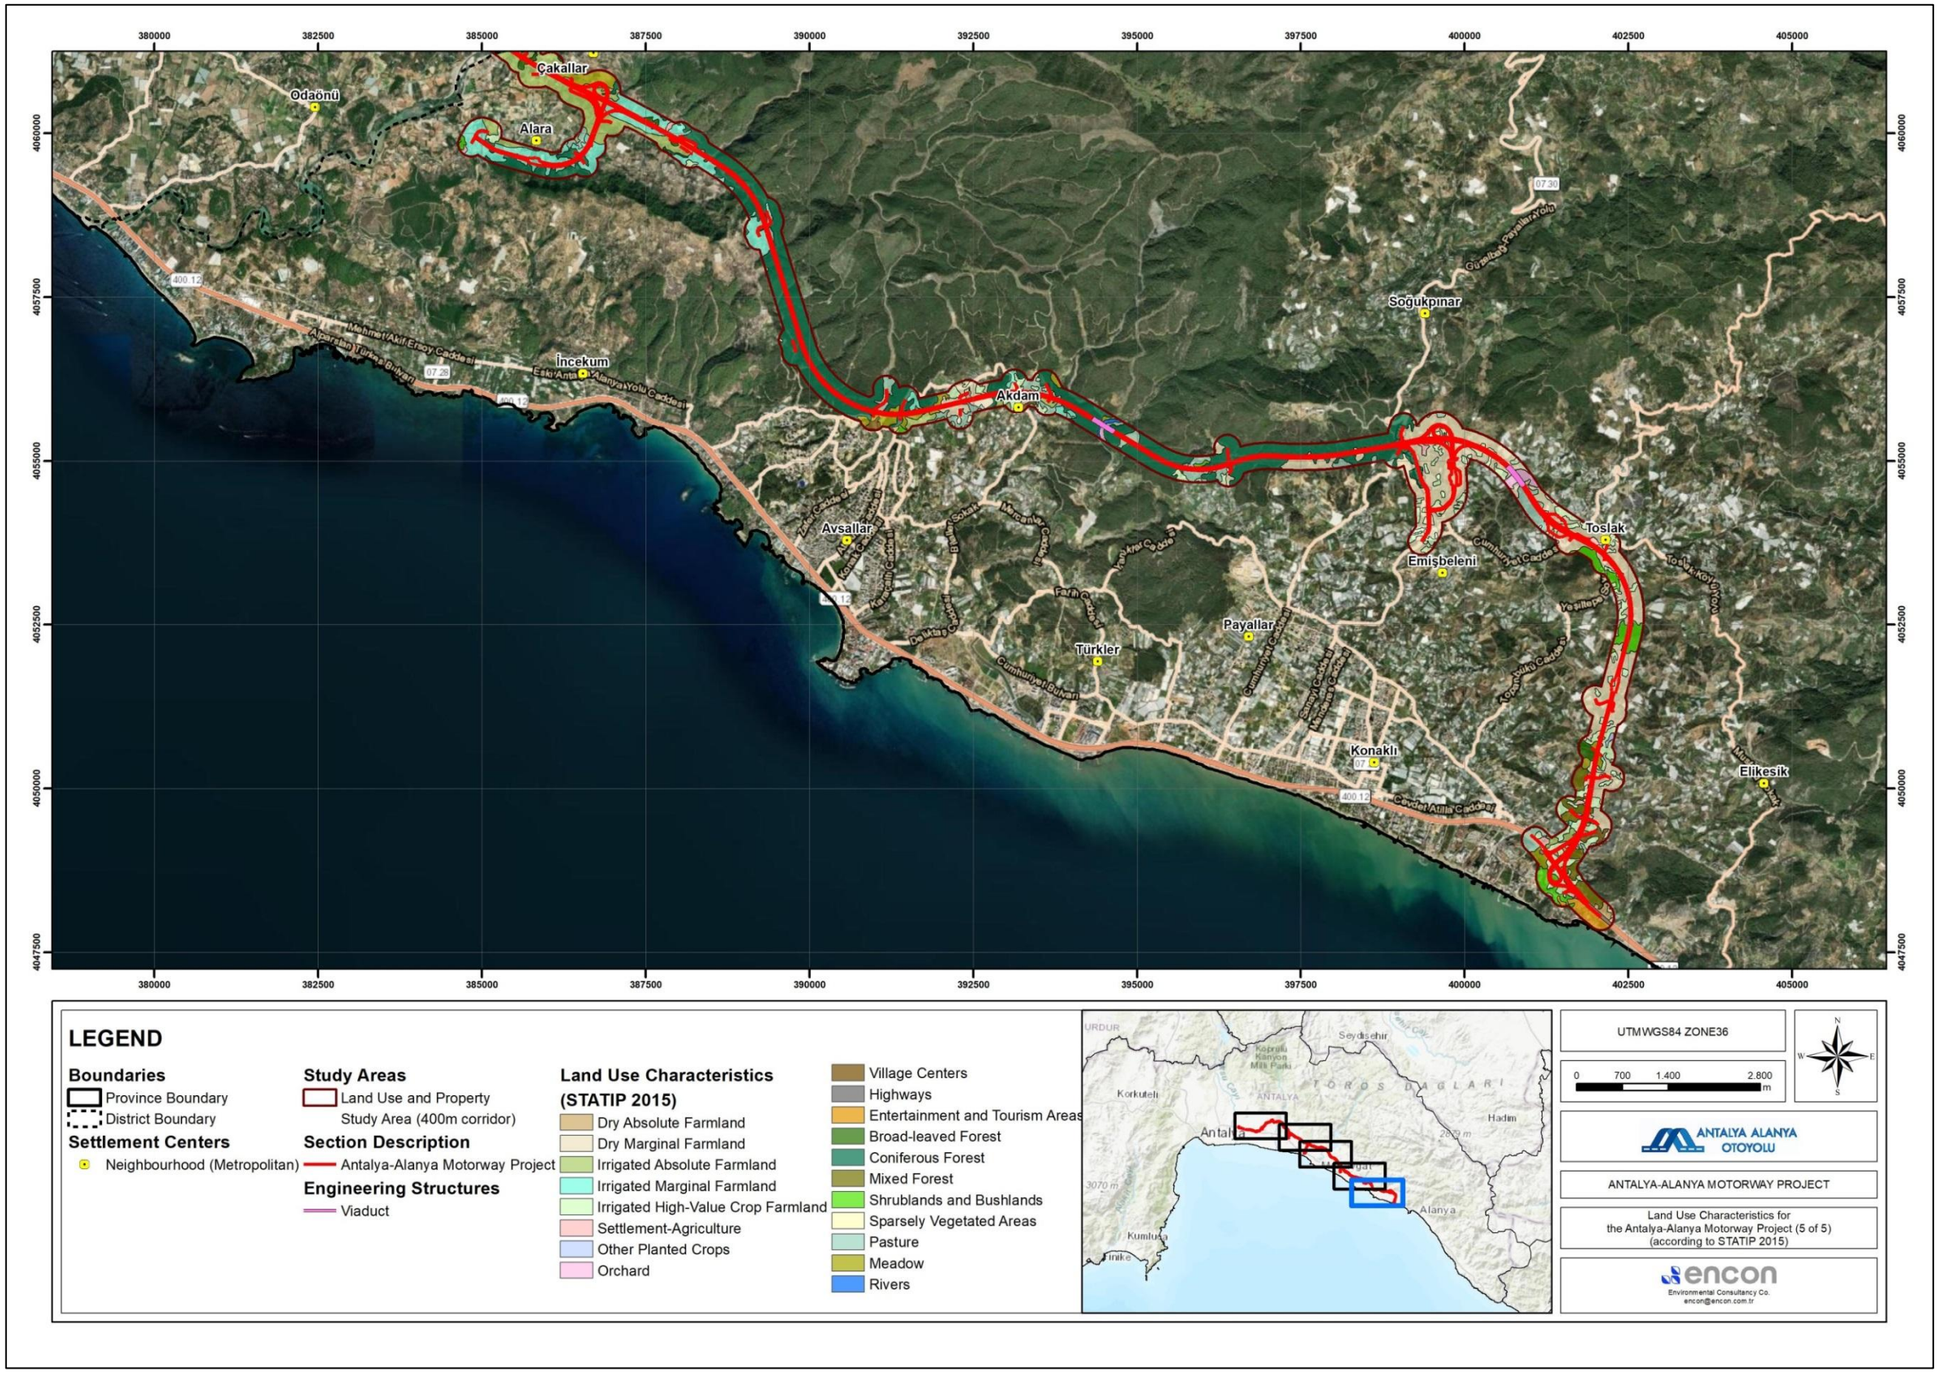

Figure V.10. Map of Land Use Characteristics for the Project according to STATİP 2015 (5 of 5)

The key findings of the analyses done based on STATİP-2015 database for the total study corridor of 6,856.13 hectares is summarized below.

Based on the STATİP-2015 classification system, agricultural areas constitute the predominant land use type within the project corridor, accounting for 63.33% (4,341.80 ha) of the total land cover. Within this category, irrigated agricultural areas dominate with 3,083.80 ha (44.98%), primarily made up of irrigated absolute and high-value crop lands (2,620.30 ha; 38.22%). Dry agricultural lands are the second largest sub-category (857.83 ha; 12.51%), consisting mainly of dry-marginal agricultural areas (772.28 ha; 11.26). Other notable agricultural sub-categories include orchard lands (339.08 ha; 4.95%) and settlement-agriculture types (59.83 ha; 0.87%).

Forest areas form the second most extensive land use category, covering a total of 1,991.45 ha, which corresponds to 29.05% of the project corridor. Among these, coniferous forests are the most prominent, occupying 1,165.51 ha (17.00%). Shrublands and bushlands also contribute significantly with 605.40 ha (8.83%), followed by mixed forests (149.17 ha; 2.18%) and broad-leaved forests (71.38 ha; 1.04%).

Meadow and pasture areas cover a limited portion of the project corridor, totaling 338.85 ha (4.94%). These areas are predominantly made up of pasturelands, which account for 227.04 ha (3.31%), while meadowlands represent 111.80 ha (1.63%) of the corridor.

Settlement areas, which include both residential and non-residential built-up zones, occupy a relatively small portion of the corridor, totaling 122.22 ha (1.79%). Within this category, the most notable components are village centers (26.74 ha), industrial areas (46.65 ha), and entertainment/tourism zones (36.29 ha).

Natural and semi-natural areas have minimal representation in the project corridor, covering 8.74 ha (0.12%). Similarly, meadow and pasture areas make up 338.85 ha (4.94%), predominantly consisting of pasturelands (227.04 ha; 3.31%) and meadowlands (111.80 ha; 1.63%).

Finally, water bodies, represented solely by river areas, account for a small fraction of the land use, with a total area of 53.07 ha (0.77%).

The land use distribution along the project corridor, as classified under the STATİP-2015 system, is predominantly composed of agricultural and forested areas. Agricultural areas, particularly irrigated lands, represent the majority land use, followed by forest areas with notable coverage of coniferous and shrubland types. Other land uses such as settlements, meadows-pastures, natural and semi-natural areas, and water bodies constitute relatively smaller proportions of the overall corridor.

V.2.1.3. Land Use Characteristics and Capabilities according to Land Use Database of the former Turkish General Directorate for Rural Services (GDRS)

Former Turkish General Directorate for Rural Services (GDRS) developed national land use and soil characteristics databases for all provinces based on the surveys performed by the General Directorate for Soil and Water (TOPRAKSU, one of the founding institutions of the Turkish General Directorate for Rural Services) in 1966-1971 and updated in 1982-1984 (former Ministry of Environment and Forestry, 2004). Land use and soil database for Antalya were established in 1993.

GDRS database defines the land use capabilities in eight (8) different classes as summarized in Table V.5. These classes represent the agricultural potential of the soil. In this classification system, soils are categorized between Class I, which represent the arable lands on which agricultural activities can be conducted in the most efficient, economic and simplest way without causing erosion, and Class VIII, which represent the lands that are not arable, cannot even be used as grassland or forest areas but support only wildlife development or can be used as resting area or national park by human. Characteristics of each class are summarized in Table V.5 (*Former Ministry of Agricultural and Rural Services, 2008*).

Table V.5. Agricultural Potentials Represented by Different Land Use Capability Classes and Their Characteristics

Class	Agricultural Potential	Definition of Land Use Capability
Class I	Agricultural lands suitable for agricultural soil cultivation	Class I lands are; flat or near flat, deep, fertile and easily cultivated so that the conventional agricultural methods can be applied; potential for water and soil erosion are minimal; have good drainage; are not prone to flood damage exposure; suitable for hoe plants and other intensively grown crops; Class I irrigated lands with low precipitation rates have slope values less than 1% slope, loamy structure, good water holding capacity and medium level permeability.
Class II		Class II lands are decent lands that can only be processed after taking some special precautions. Their difference from Class I lands is one or more of the limiting factors such as slight slope, moderate exposure to erosion, moderately thick soil, exposure to occasional moderate floods and a moderate level of moisture that can easily be isolated.
Class III		Class III lands are moderately good lands for hoe plants which can generate solid income provided they are utilized with a good cropping system and proper agricultural methods. Moderate slope, increased erosion sensitivity, excessive moisture, exposed soil, presence of stones, having a lot of sand and/or gravel, low water holding capacity and low yield are properties of this type of land.
Class IV		Class IV lands can be constantly utilized as meadows. Field crops can also be occasionally grown. High levels of slope, bad soil characteristics, erosion and climate are the factors limiting agricultural activities on these lands. Soils with low slopes and poor drainage are also classified as Class IV lands. These soils are not subject to erosion, but they are unsuitable for growing many agricultural products as they have a low yield and a tendency to suddenly dry up in the spring. In semi-arid regions, cropping systems incorporating legumes are generally not possible due to climate.
Class V	Agricultural lands not suitable for soil cultivation	Class V lands are reserved for long-life plantations such as meadows and forests as they generally are unsuitable for cultivated plants. A few factors such as stony structure and sogginess hinder cultivation here. The land is flat or near-flat. It is not subject to an excessive amount of wind and water erosion. Grazing and tree logging activities can be carried out on condition that a good soil cover is constantly maintained.
Class VI		Class VI lands require moderate precautions even when they are used as forest or meadow since they have quite a bit of slope and are subject to severe erosion. Exposed, soggy or very dry conditions make this type of land unsuitable for cultivation.
Class VII		Class VII lands have high slope, are stony and have been subject to violent erosion. Exposed soils, dry and/or some unfavourable conditions and swamps can be classified as Class VII soil. These can be used as forest or meadow without showing due care. If the vegetation on these soils diminishes, erosion can get quite violent.
Class VIII	Non-arable lands	Class VIII lands exhibit features that prevent them from being used as forest, meadow or cultivated land. This type of land is habitat to wild life and can also be used for recreational purposes or as catchment basins for streams. These include lands containing marshes, swamps, deserts as well as areas of high mountainous regions, rocky lands or lands with very deep craters.

Source: Former Ministry of Agricultural and Rural Services, 2008

The former Ministry of Agriculture and Rural Services, in its Technical Procedure on Soil and Land Classification Standards of 2008, specifies the suitability of different land classes for cultivation, grazing and forestry activities. These are summarized in Table V.6.

Table V.6. Usage Suitability Matrix for Different Land Use Classes

Land Use Capability Class	Wild life	Forestry	Grazing			Cultivation			
			Limited	Moderate	Intensive	Limited	Moderate	Intensive	Very Intensive

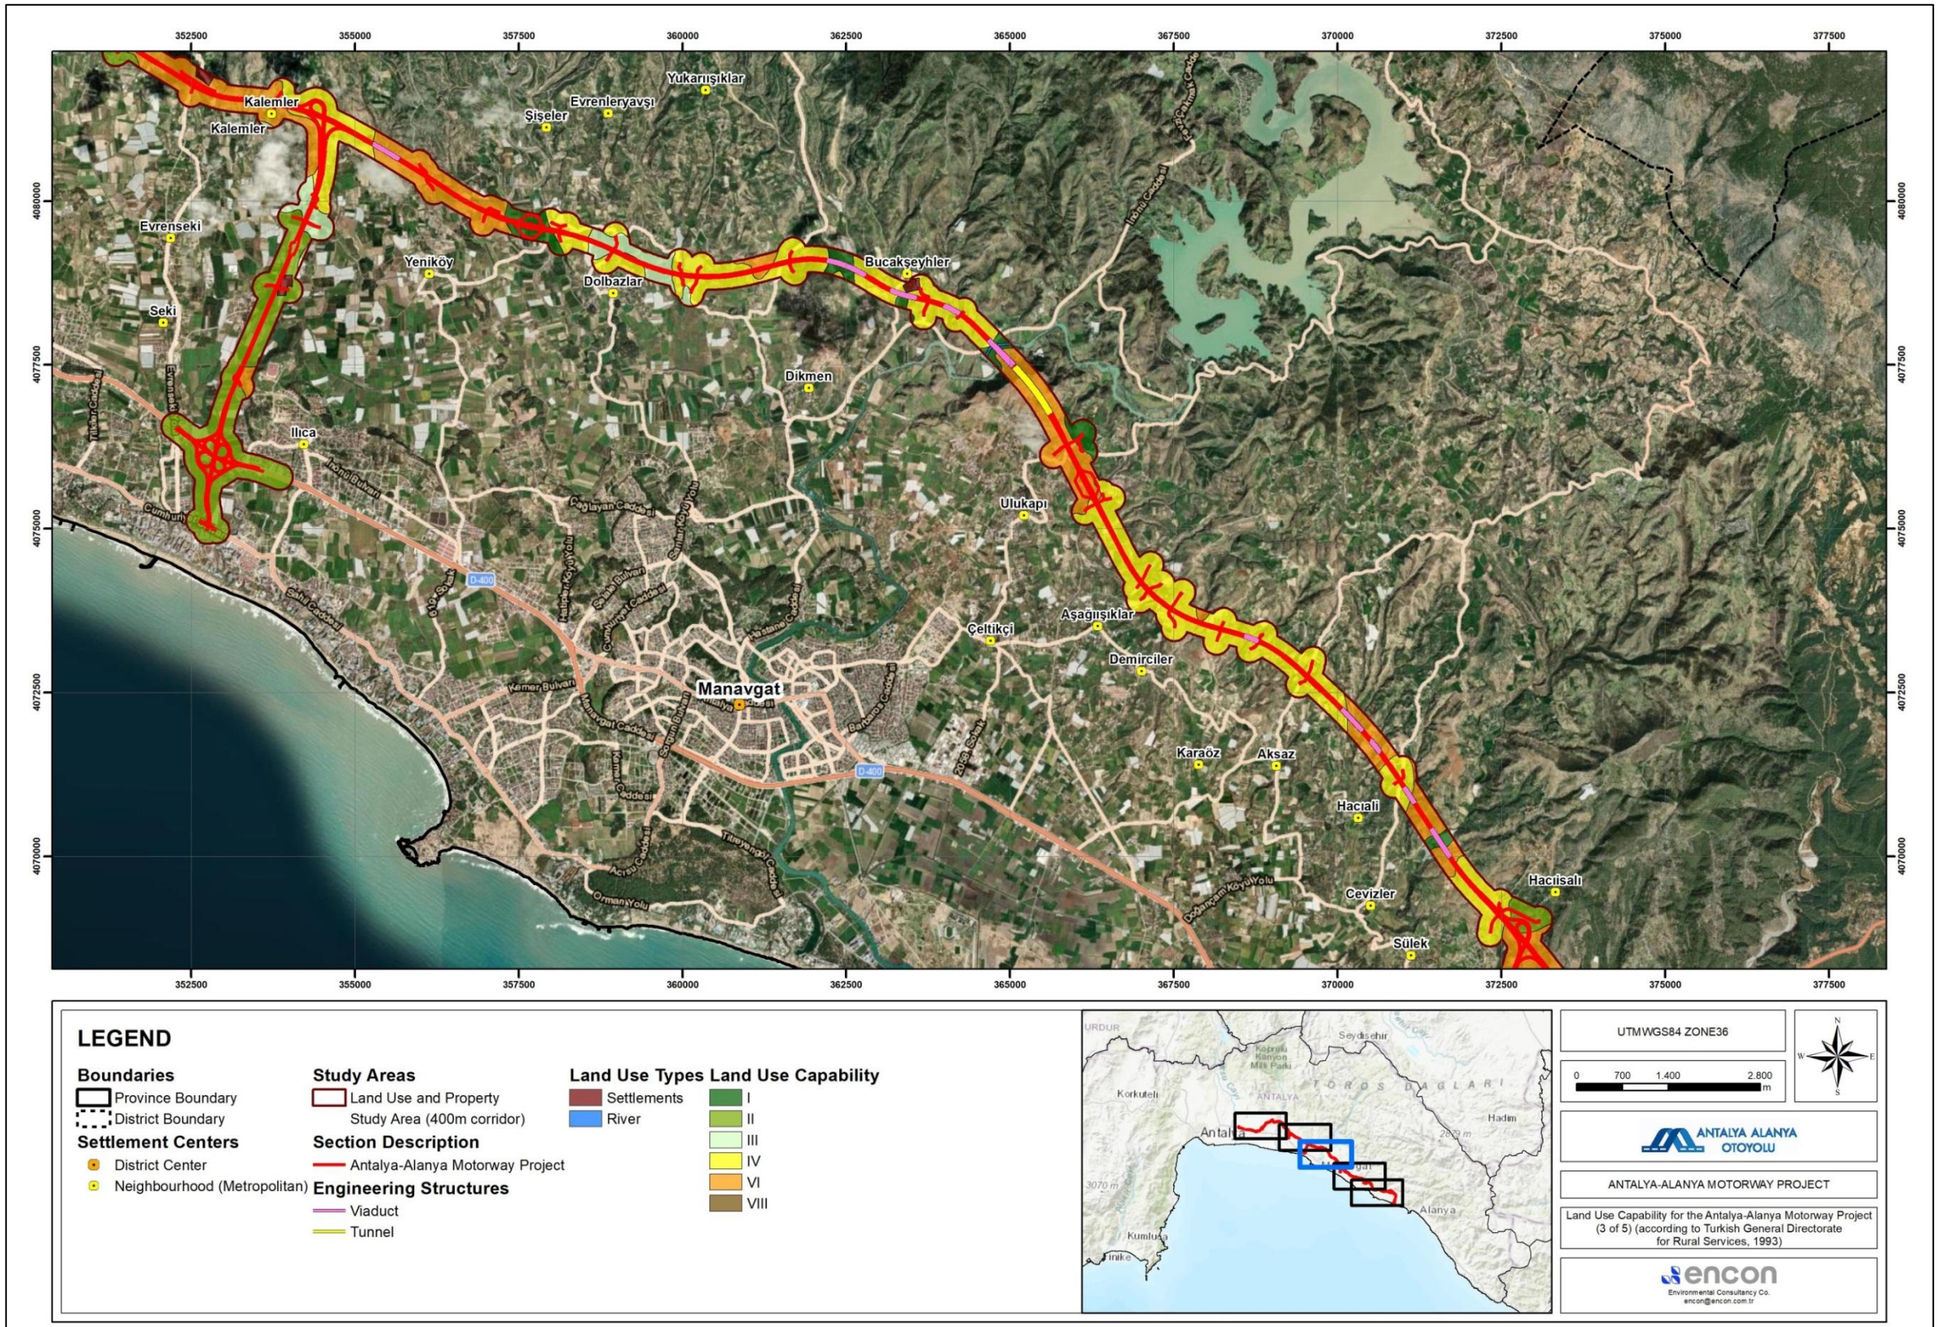

Figure V.18. Map of Land Use Capabilities for the Project according to the GDRS, 1993 (3 of 5)

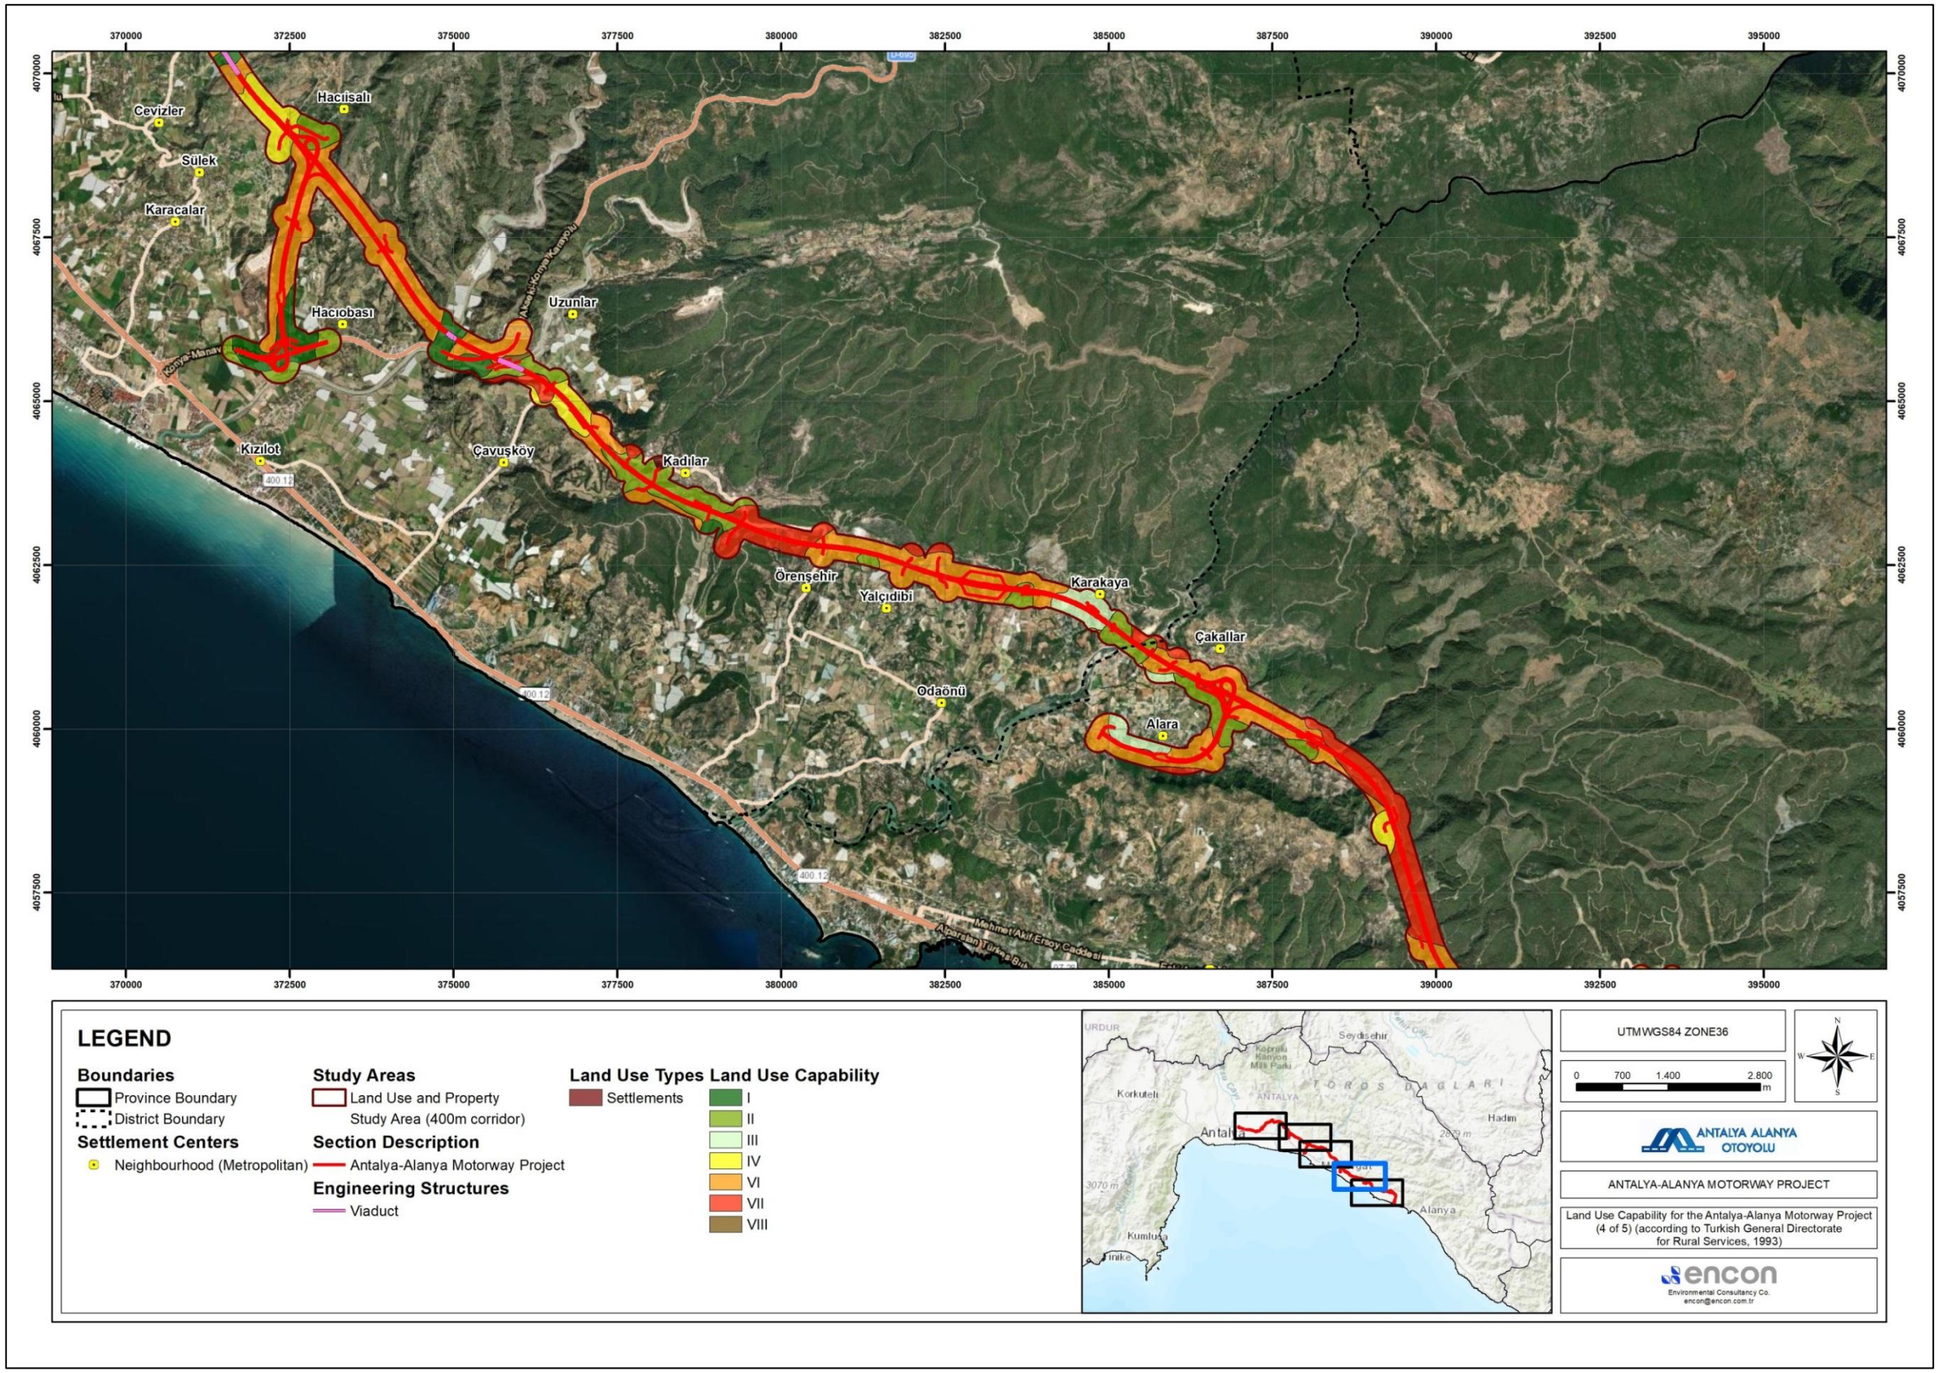

Figure V.19. Map of Land Use Capabilities for the Project according to the GDRS, 1993 (4 of 5)

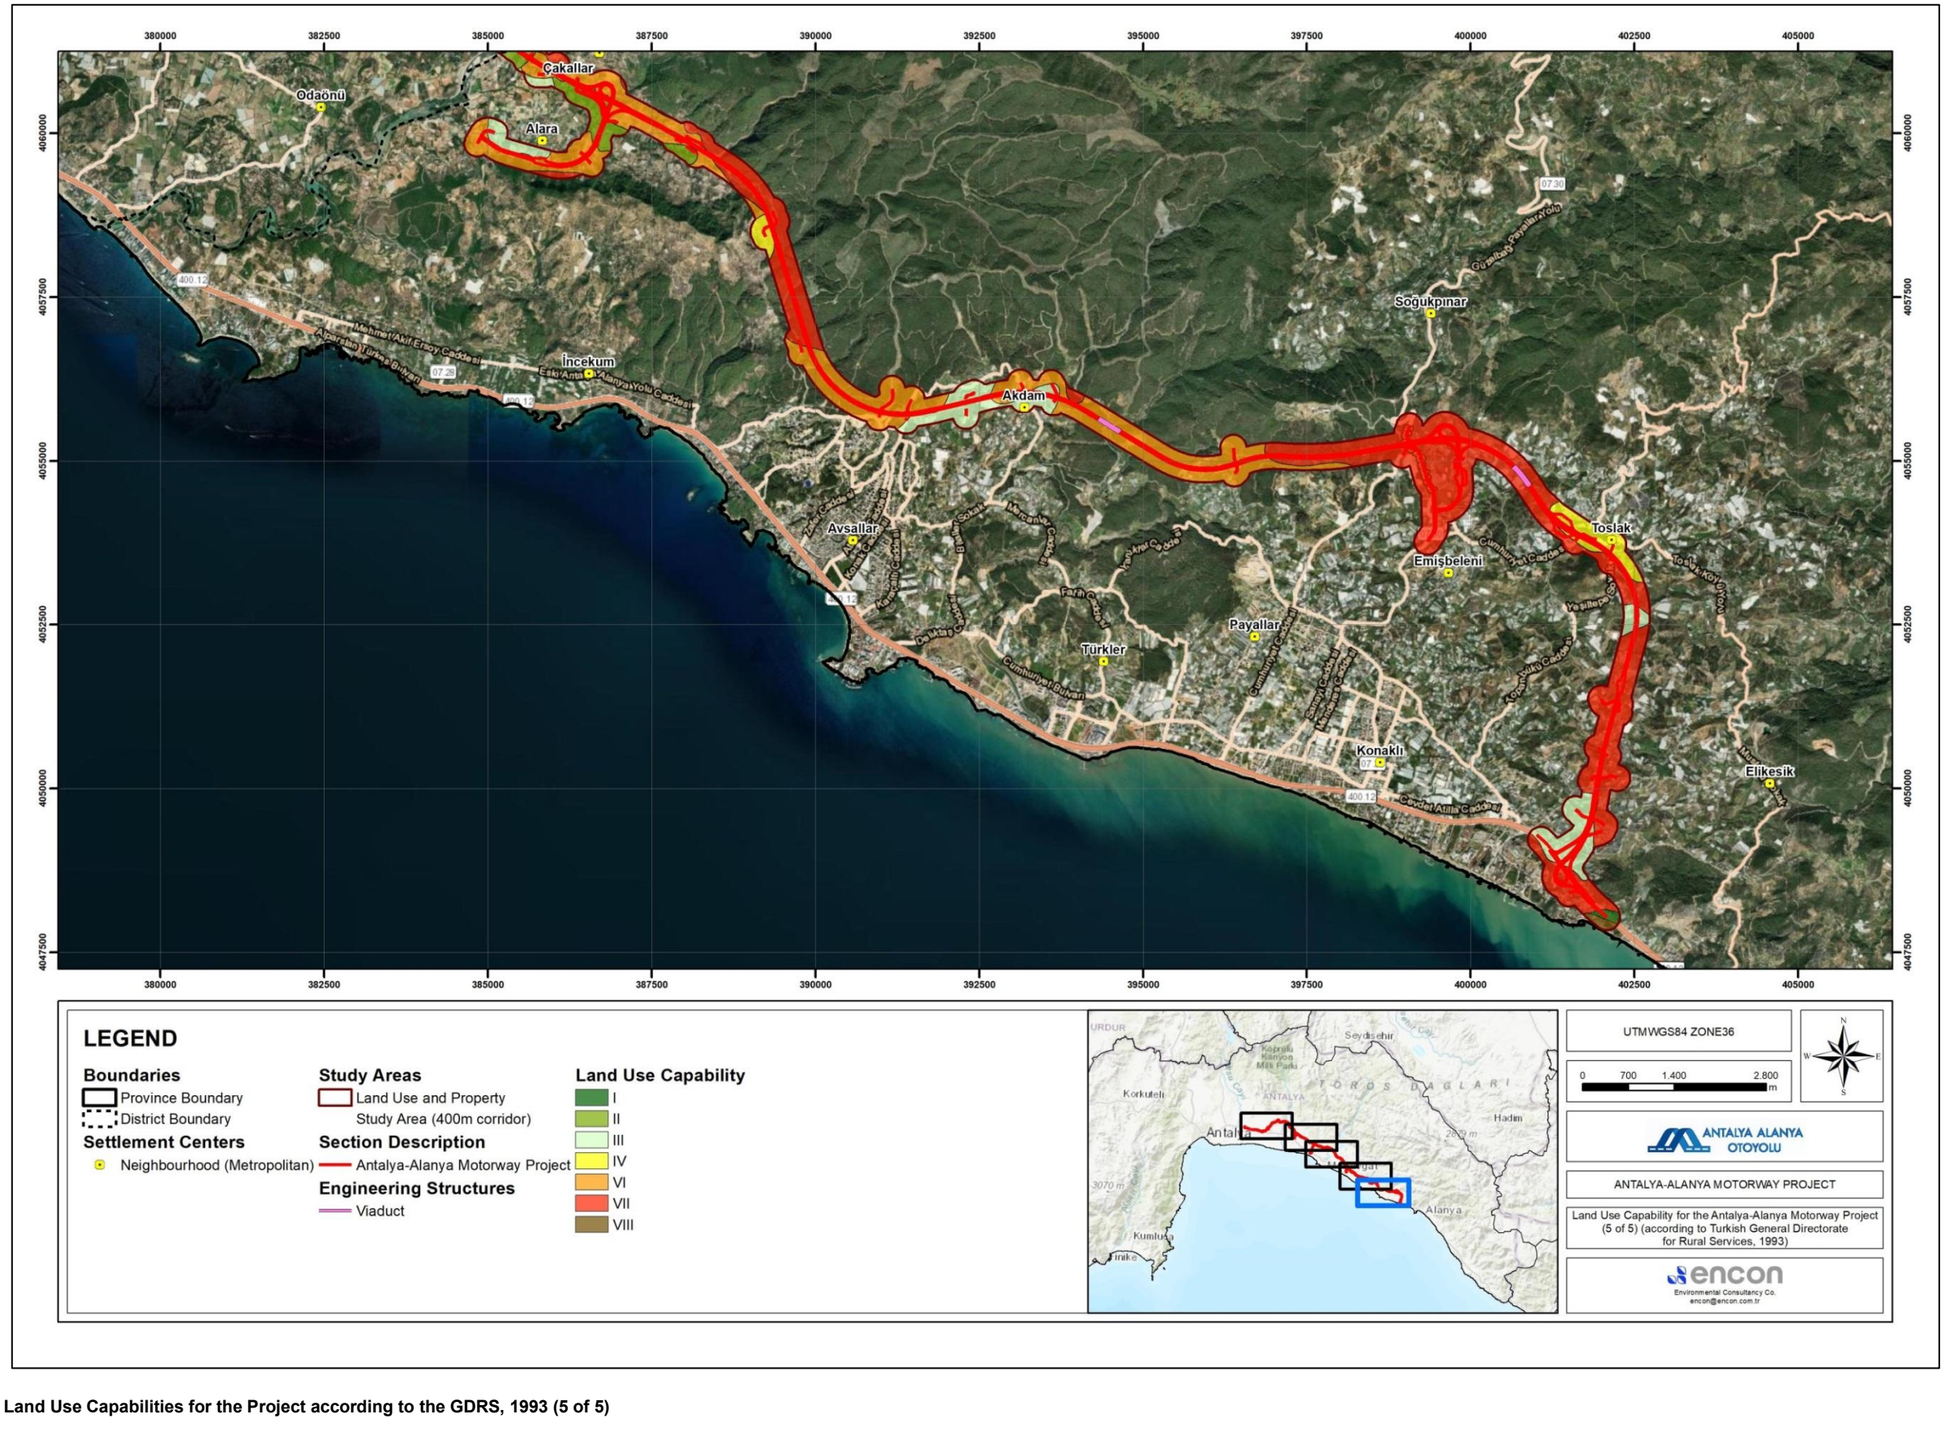

Figure V.20. Map of Land Use Capabilities for the Project according to the GDRS, 1993 (5 of 5)

According to GDRS, the study area comprises a mix of lands with varying degrees of agricultural, ecological, and economic value. The land use capabilities of the soils corresponding to the study corridor are presented in Table V.7 and have been interpreted in accordance with the guidance provided by GDRS.

The most extensive land use category in the corridor is irrigated farmland, covering 2,034.16 hectares, which constitutes 29.67% of the study area. These lands are classified under Capability Classes I (454.44 ha; 6.63%), II (1,114.10 ha; 16.25%), and III (465.71 ha; 6.79%), all of which are considered suitable for intensive to moderately intensive cultivation.

The second largest land capability group in terms of total area is shrubbery, with 2,027.07 hectares, making up 29.56% of the corridor. These areas are classified as Class VI (900.62 ha; 13.13%), Class VII (694.96 ha; 10.14%), Class IV (407.10 ha; 5.94%), and Class III (24.38 ha; 0.35%).

Dry farmland (non-fallow), which occupies 1,554.59 hectares (22.53%), is mainly distributed across Classes VI (566.93 ha; 8.27%), IV (463.40 ha; 6.76%), III (262.78 ha; 3.83%), and II (245.93 ha; 3.59%).

Forest areas, which span 988.19 hectares (14.41%), fall within Class VII (503.10 ha; 7.34%) and Class VI (485.09 ha; 7.07%). These lands are marked by significant limitations, including steep terrain, shallow or stony soils, and susceptibility to erosion.

Dry farmland (fallow) lands covers 101.99 ha (1.49%) consisting of Classes IV (71.28 ha; 1.04%), VI(16.91 ha; 0.25%), III(13.80 ha; 0.20%).

Pasture lands, although limited in spatial extent at 21.09 hectares (0.31%), are also classified under Class VII, reinforcing their restricted usability.

In conclusion, the GDRS-based land use capability assessment demonstrates a landscape where productive agriculture is feasible on Classes I–IV lands, particularly for irrigated use, while Classes V–VIII exhibit varying degrees of constraint that require controlled or conservation-oriented land use.

The key findings of the land use capability analyses are summarized below (settlement areas, ponds and rivers that cover 0.33% of the study corridor and not categorized under any of the land use capability classes are not taken into consideration in the following figures):

- Lands suitable for soil cultivation (Classes I, II, III and IV) cover 52.44% of the study corridor (3,595.64 ha).
- Lands not suitable for soil cultivation (Class VI and VII) cover 46.50% (3,188.77 ha) of the study corridor.
- Class VIII lands (non-arable lands) cover 0.71% of the study corridor (48.89 ha).

Table V.7 indicates the suitability of different land classes for cultivation, grazing and forestry activities. Class VIII lands are not suitable for cultivation, grazing or forestry activities and can only provide habitat use for wildlife components. Similarly, Class VII lands are only suitable for forestry and grazing activities to a limited extent.

V.2.1.4. Comparison of Study Area for Different Land Use Types

A comparison of the areas occupied by different land use types under CORINE (2018), STATİP (2015) and GDRS (1993) databases is provided in Table V.8 to allow an evaluation of the changes within years. It should be noted that the classification system of the three databases differs and the following comparison is given to provide a general overview of the development.

Table V.8. Comparison of Areas for Different Land Use Types According to CORINE (2018), STATIP (2015) GDRS (1993) Databases

Land Use Type	Data Source					
	CORINE (2018)		STATİP (2015)		GDRS (1993)	
	Area (ha)	Percent (%)	Area (ha)	Percent (%)	Area (ha)	Percent (%)

Total	**6,856.13**	**100.00**	**6,856.13**	**100.00**	**6,856.13**	**100.00**

V.2.1.5. Forestlands

In 1993, Helsinki Process began with the aim of developing guidelines for the sustainable management of forests in Europe. The Process has sought to identify measurable criteria and indicators for the evaluation of how European countries have progressed in their efforts to follow the principles of sustainable forest management and conservation of the biological diversity of European forests. The guidelines developed in the scope of the process concluded that forest resources and forest lands should be sustainably managed to meet the social, economic, ecological, cultural and spiritual human needs of present and future generations. In alignment with the outcomes of the Helsinki process, Turkish Regulation on the Forestry Management categorizes the forestry functions under three groups as ecological, social/cultural and economic and attributes specific management goals for each sub-function as listed in Table V.9.

Forests with economic functions are operated/managed with the aim of production of forest products (wood and non-wood) having economic value and meet the economic demand for these products in a continuous and regular way. These forests are particularly allocated to economic functions, while they can co-perform other functions (e.g. ecological) as well. This function includes areas (i.e. wood productions forests) that are suitable for forest maintenance and regeneration works both in terms of growing conditions and also social considerations.

Some of the forests are established on sensitive ecological balances and shelter high ecological value so that these forests primarily serve for ecological functions as the irreversible impacts of forest production activities cannot be tolerated on such environments. Consequently, even if these types of forests have an economic value in terms of forest product production, conservation of them for their ecological value or environmental functions becomes the first priority.

Forests having social and/or cultural functions primarily serve for the protection of public health by preventing noise and/or air emissions and aesthetic and scientific research purposes and provide recreational areas for natural activities, sports, ecotourism purposes, etc. Forest zones in the vicinity of motorways or railways, having a width of minimum 50-100 m, are considered to be effective in mitigating the adverse impacts of noise generation and forming an aesthetic view.

Table V.9. Functions of Forests and Associated Management Goals

Functions	General Forestry Functions	Management Goals
Economic	Forest products production	Industrial plantation
		Quality and featured wood production
		Industrial wood production in maximum capacity
		Firewood production
		Others (specific afforestation, etc.)
		Production of non-wood forestry products
		Honey production areas
		Herbal products
		Animal products
		Water and mineral products
Ecological	Nature protection	Nature protection
		Gene conservation forest
		National Park
		Protection forest
		Nature Park
		Nature protection area
		Wildlife protection and development sites
		Alpine zone
		Natural old growth forest
		Ecological transition zone
		Sensitive ecosystems
		Coastal forests
		Forest ecosystem improvement areas
		Very unfavorable growth grounds
		Areas with very high protection value
		High mountain forest ecosystems
		Seed stands
		Seed orchards
		Areas to be protected from social stress
		Wild life protection and management sites of General Directorate of Forestry
		Biological diversity conservation and development areas
	Erosion protection/	Avalanche prevention

Functions	General Forestry Functions	Management Goals
	Soil conservation	Landslide prevention
		Stone and rock fall prevention
		Soil conservation
		Flood prevention
	Climate protection	Forests primarily allocated to climate protection
Social/ Cultural	Hydrological	Drinking water protection
		Utility water protection
		Conservation of water resources
	Public Health	Noise prevention
		Air pollution prevention
		City forests
		Protection of health facilities
	Aesthetics	Road protection for aesthetic purposes (green road)
		Aesthetic appearance
	Ecotourism and recreation	Nature trekking areas
		Rock climbing sites
		Bird watching sites
		Recreational areas (picnic areas, fest areas, etc.)
		Sports area
		Hunting area
		Tourism intended forests
	National security	Military installations and drill sites
		National border and strategic areas
	Scientific	Research intended areas
		Arboretum research forest
		Educational purposes
		Faculty research
		Forestry research forest

The Project falls within the jurisdiction of four (4) different Forestry Management Directorates (Serik, Taşağıl, Manavgat and Alanya) under Antalya Regional Directorate of Forestry as summarized in Table V.10.

Table V.10. Relevant Forestry Directorates for the Project

Regional Directorate	Forestry Management Directorate	Management Sub-directorate
Antalya Regional Directorate of Forestry	Serik Forestry Management Directorate	Serik Forestry Management Sub-directorate
		Akbaş Forestry Management Sub-directorate
	Taşağıl Forestry Management Directorate	Taşağıl Forestry Management Sub-directorate
		Çardak Forestry Management Sub-directorate
	Manavgat Forestry Management Directorate	Şelale Forestry Management Sub-directorate
		Naras Forestry Management Sub-directorate
		Manavgat Forestry Management Sub-directorate
		Yalçıdibi Forestry Management Sub-directorate
	Alanya Forestry Management Directorate	Alara Forestry Management Sub-directorate
		Avsallar Forestry Management Sub-directorate
		Kargı Forestry Management Sub-directorate

According to CORINE (2018) database, forestlands (including the broad-leaved forests, coniferous forest and mixed forest) cover 10.54% (722.65 ha) of the entire study corridor (6,856.13 ha).

According to STATİP (2015) database, forestlands (including the broad-leaved forests, coniferous forest, mixed forest and shrublands) cover 29.05% (1,991.45 ha) of the entire study corridor (6,856.13 ha).

According to GDRS (1993) database, forestlands cover 14.4% (988.19 ha) of the entire study corridor (6,856.13 ha).

Forest Management Plans prepared by the relevant Forest Management Sub-Directorate will be used to analyze the forest areas of the Project. Forest Management Plans cover both the actual forests where forest cover (e.g. trees) are present at different density levels and open areas where forest cover is absent (unwooded forest soils) or where uses other than forestry such as settlement, agricultural, quarry, etc. are present. Forest Management Plans categorize the actual forests as high forests and coppice forests. Each category is further classified as productive forests where canopy cover rates ranges between 11-100% and degraded forests, where canopy cover rate is lower than 10%. Classification of canopy levels as 1, 2 and 3 according to the density of cover is done as summarized inTable V.11.

Table V.11. Canopy Cover Classification According to Forest Management Plans

Canopy Cover Classification	Canopy Cover Levels	
	Symbol	Rate (%)
Absent to sparse	-	0-10
Sparse	1	11-40
Moderately closed	2	41-70
Closed to fully closed	3	71-100

Areas of actual forests (covered by forest vegetation) and open areas corresponding to the study area according to their functions and canopy levels have been analyzed by using the Forest Management Plans and the relevant database. The results of the analyses are presented in Table V.12.

Table V.12. Distribution of Forestlands according to their Functions and Types within the Study Area

Forest Functions			Area of Actual Forests (ha)								Open Areas (ha)												
			High Forests				Coppice Forests																
			Canopy Cover Classification				Canopy Cover Classification																
			Productive			Degraded	Productive			Degraded													
			Level 3 (71-100%)	Level 2 (41-70%)	Level 1 (11-40%)	(0-10%)	Level 3 (71-100%)	Level 2 (41-70%)	Level 1 (11-40%)	(0-10%)

Sub-total (Canopy Levels)			190.84	143.77	67.89	54.51	0.00	0.00	0,00	0,00													
Total (Actual Forest/Open Area Type)			457.01				0,00				27.05	46.58	4.87	10.28	4.60	1.75	33.23	0.24	9.88	1.10	2.26	1.39	1,186.36
Total (Actual Forests/Open Areas)			457,01								1,329.60												
Grand Total			1,786.61																				

According to the data derived from the Forest Management Plans and presented in Table V.12, within the study corridor, there is no forest specified as “coppice forest”, and thus all of the actual forests are categorized as high forests having different canopy covers. The key findings of the analyses done based on the relevant Forest Management Plans of the study area are summarized below:

Almost 88% (402,5 ha) of the actual forests are productive, where the canopy cover level changes between 11-100%, while the remainder 12% (54,51 ha) correspond to degraded forests where the canopy cover level is less than 10%.

In terms of forest functions, the majority of the actual forest areas 381.35 hectares, corresponding to 83.69% of total actual forests are designated for economic purposes, mainly for industrial wood production, maximum capacity timber production, and herbal product harvesting.

Forests allocated for ecological functions, such as nature protection, soil conservation, and erosion control, cover 35.35 hectares, accounting for approximately 7.73% of all actual forest areas.

The remaining social and cultural forest functions including areas dedicated to ecotourism and recreation and aesthetic use cover 39.07 hectares, which corresponds to around 8.51% of the total actual forest area. This classification highlights that forestlands within the project area are predominantly utilized for economic forestry purposes, with limited areas serving ecological and sociocultural roles.

Table V.13. Land Use Properties and Forestlands according to Stand Types within the Expropriation Corridor

Forest Stand Types	Section 1		
	Area (m^2)	Area (ha)	Percent(%)

V.2.1.6. Agricultural Lands

According to CORINE (2018) database, agricultural areas (including the arable lands, permanent crops and heterogeneous agricultural areas) cover 76.06% (5,214.46 ha) of the entire study corridor (6,856.13 ha).

According to STATİP (2015) database, agricultural areas (including the dry, irrigated, mixed and planted agriculture areas) cover 63.33% (4,341.80 ha) of the entire study corridor (6,856.13 ha).

Assuming that the land use capabilities given for the study corridor according to GDRS database previously in Table V.7 are applicable to the current situation, Table V.14 provides an overview of the land use capabilities of the agricultural areas within the study corridor. As can be seen, a major part (36.3%) of the agricultural lands consists of soils having Class II land use capability. Class II lands are decent lands that can only be processed after taking some special precautions. Their difference from Class I lands is one or more of the limiting factors such as slight slope, moderate exposure to erosion, moderately thick soil, exposure to occasional moderate floods and a moderate level of moisture that can easily be isolated.

Table V.14. Land Use Capabilities of the Agricultural Areas within the Study Corridor (according to Turkish General Directorate for Rural Services, 1993)

Land Use Capability Class	Area (m^2)	Area (ha)	Percent (%)
I	4,599,930.62	459.99	12.27
II	13,599,393.62	1,359.94	36.28
III	8,095,488.95	809.55	21.60
IV	5,346,802.43	534.68	14.27
VI	5,838,424.14	583.84	15.58
Total	**37,480,039.76**	**3,748.00**	**100.00**

Land use capability of soils for the study area on settlement-basis is presented in
According to the data presented in the table, the largest land cover within the study area is agricultural land, which spans 1,186.36 hectares, corresponding to 66.06% of the total area assessed (1,795.95 ha). This is followed by Red Pine forests, which cover 399.16 hectares, making up 22.23% of the total area. Other notable land cover types include degraded forest areas (54.51 ha; 3.04%) and settlements (33.23 ha; 1.85%).

Table V.15.

According to the data presented in the table, the largest land cover within the study area is agricultural land, which spans 1,186.36 hectares, corresponding to 66.06% of the total area assessed (1,795.95 ha). This is followed by Red Pine forests, which cover 399.16 hectares, making up 22.23% of the total area. Other notable land cover types include degraded forest areas (54.51 ha; 3.04%) and settlements (33.23 ha; 1.85%).

V.2.1.7. Pasture Lands

According to CORINE (2018) database, pasturelands are not present within the study corridor. According to STATİP (2015) database, pasturelands are 3.31% for the Project and total area of pastureland is 227.04 ha. According to GDRS (1993) database, pasturelands are 0.31% for the Project and total area of pastureland is 21.09 ha. The pasture areas included in the STATİP 2015 data are within the scope of the Pasture Law No. 4342. It should be noted that; in this study, regardless of whether it is within the scope of the Law or not, the land is determined based on its current use according to its natural structure.

Additionally, in the scope of the socio-economic field interviews conducted (see Chapter 14 “Socio-economic Environment”), availability of pasturelands in the neighborhoods has been identified by means of questionnaires conducted with the mukhtar. It was stated that the pasturelands in the villages do not occupy a large amount of area. Therefore, there will not be a major impact in terms of pastureland in the villages where fieldwork is carried out.

V.2.2. Property and Ownership within the Expropriation Corridor

According to ownership, the lands corresponding to the Motorway and its components including the campsites, quarry, borrow pits, and storage areas are mainly categorized as follows:

- Privately owned lands
- State-owned lands (i.e. treasury lands, forestry, pasture lands, etc.)
- Lands owned by legal entities
- Litigious
- Co-owned by Private and State

Table V.16 presents the number of parcels and the corresponding land areas within the expropriation corridor for each section of the Motorway. As shown, the total area subject to expropriation is 1,559.53 ha.

The largest portion of this area is privately owned land, comprising 777.73 ha, 59.2% of the total. The second largest share is state-owned land, covering 746.71 hectares (36.6%). Within this category, treasury-forestry lands constitute the most substantial portion, with 462.10 hectares of the state-owned land.

The remaining area, approximately 35.3 ha, is distributed among legal entities, litigious lands, and lands co-owned by private individuals and the state.

Table V.16. Distribution of Lands According to Type of Ownership and Number of Corresponding Parcels within the Expropriation Corridor

Types of Ownership	Area (m^2)	Area (ha)	Number of Parcels	Ratio (%)
Privately-owned	7,777,271.86	777.73	2,085	59.2
State-owned	7,467,144.33	746.71	1,291	36.6
Treasury	1,302,505.63	130.25	810	23.0
Treasury – Forestry	4,621,025.44	462.10	136	3.9
Non-registered – Forestry	753,139.12	75.31	7	0.2
Treasury – Pasture	1,778.30	0.81	3	0.1
Non-registered (creek, park, road)	660,460.92	66.05	307	8.7
Non-registered (others)	128,234.92	12.82	28	0.8
Legal Entity	180,358.54	18.04	108	3.1
Litigous	129,990.61	13.00	26	0.7
Co-owned by Private & State	42,267.83	4.23	14	0.4
Total	**15,595,254.87**	**1,559.53**	**3,524**	**100.00%**

V.3. Potential Impacts

Land use and transportation are intrinsically related. Motorway development projects result in changes in the land use patterns and ownership structure along their route. Depending on the length of the

route and the width of the road and expropriation corridor, magnitude of the impacts would change. Similarly, the sensitivity of the affected lands (i.e. ecological importance, social and economic value to users, etc.) to be crossed by the motorway changes depending on their value, which in turn, together with the magnitude of the impact, determines the level of impact significance.

The Project will have a total length of 117.8 km, including the main carriageway and the access roads. The width of the expropriation corridor will be minimum 55 meters, whereas it may expand up to 450 meters depending on the scale of excavation and fill requirements and siting of the road structures such as interchanges, service areas, etc. Lands (within the expropriation corridor) required for the development and operation of the Motorway and its components will be acquired by the KGM prior to the start of construction activities in accordance with the relevant provisions of the national legislation (i.e., Expropriation Law numbered 2942, Forestry Law numbered 6831, Pastures Law numbered 4342, Law on Soil Conservation and Land Use numbered 5403). Total area to be acquired within the expropriation corridor will be 1,559.53 ha, which corresponds to 3.524 parcels. Following the acquisition of lands, Project activities including vegetation clearing, topsoil stripping, cut and fill operations and construction of motorway components and other buildings/facilities will result in permanent and temporary impacts that need effective management.

In addition to the direct physical impacts of the activities on the lands and socio-economic dimensions of the land acquisition, transportation projects possibly trigger further land developments in the vicinity of route, especially when the motorway provide access to lands.

In this context, direct potential impacts of the Motorway development on the land use and property and probable indirect impacts are listed below. Further assessment of the direct impacts for the land preparation and construction and operation phases, in consideration of the baseline conditions, are provided in the following headings, while evaluation of socio-economic impacts associated with land acquisition and changes in the existing land use patterns (e.g. physical or economic displacement) are provided in Chapter 14 (“Socio-economic Environment”).

- Permanent land acquisitions resulting in changes in the existing land use characteristics (i.e. agricultural, forest, pasture, etc.), physical or economic displacement;
- Temporary land acquisitions for construction facilities (i.e. construction campsites, quarry, borrow pits, storage areas) resulting in degradation of lands that need rehabilitation;
- Fragmentation of lands and restrictions on the access to lands;
- Planned and unplanned urban development in the expansion areas;
- Increased demand in residential and commercial properties resulting in a trend in increase in the property values;
- Increased demand in infrastructural services (i.e. transportation, electricity, water, wastewater, etc.).

V.3.1. Land Preparation and Construction Phase

Construction of the Motorway and its components will result in the changes in the existing land use. Accordingly, forest lands, agricultural areas, pastures, etc. corresponding to the expropriation corridor will be lost. In addition, land use characteristics corresponding to temporary construction compounds such as Camp Sites and quarries as well as permanent storage sites will also change temporarily or permanently depending on the nature of the activity. As a result of Motorway construction, the Motorway will cause permanent fragmentation of agricultural areas, forests and other lands at a number of locations, making the associated land less viable for existing owners and users through access restriction. These impacts will start to occur in the construction phase and continue during the

operation phase of the Project as well. Several culverts, underpasses and overpasses have been included in the design

For the forest lands to be used in the scope of the Project, permits have been/will be taken from the related forestry authorities. Trees located on the forest lands to be affected by the Project will be removed and evaluated by the forestry authorities. Areas of the forest and other types of lands to be affected by the Project have been identified by analyzing the expropriation plans. Number of trees to be removed have been estimated by using suitable tools (i.e. where available by using existing forest management plans, expropriation plans, GIS analyses, site surveys, etc.). Quantified assessment on each type of land use is provided below.

V.3.1.1. Temporary Impacts at the Construction Sites

Road construction sites, quarry, borrow pits, storage areas and construction campsites are the locations where temporary impacts of the construction activities may occur. In the scope of road construction works, construction activities are to be normally conducted within the expropriation corridor. For the privately-owned lands, construction activities have to start following the completion of expropriation process (in case of agreement, after payments are done; otherwise in accordance with Article 27 (“Urgent Expropriation”) of the Expropriation Law. Since the expropriation corridor is specified wide enough (minimum 55 meters and maximum 450 meters) to allow sufficient space for the works to be conducted by construction machinery and vehicle, intrusion of construction activities onto adjacent lands are normally avoided.

On the other hand, there may be exceptional cases when the construction personnel may cross the borders of the expropriation corridor (may be unintentionally or with informed decision) and pose risk of damage on the adjacent lands. Similarly, on very rare cases, drilling, land preparation or construction activities may be initiated by construction contractor before the expropriation or court decisions are finalized. To avoid such incidents and associated risks or damages to land and its owners/users, it is essential to manage construction personnel properly and strictly adhere to the expropriation corridor boundaries. If occurs, the impact would most likely be reversible by corrective measures to be taken.

The area to be covered by known construction components such as Camp Sites, quarries, storage sites, etc. and the corresponding land uses are summarized in Table V.17.

Total					**851.77**		

* The areas presented in the table have been calculated based on the aread provided in the RAP Report.
** Concrete Plant 2, Mechanical Plant 1 and Asphalt Plant 1 are located within the same area as the Temporary Camp Site.

As can be seen from the table, the majority of the construction components are located on forest lands, which occupy 221.92 hectares of the total 253.83 hectares allocated for construction. The lands on which the camp sites are established will be temporarily affected during the construction period, except for the main construction camp, which will remain permanently as it will serve as the O&M Centre during the operation phase. According to the BOT contract, the construction period is limited to a maximum of three years, during which the temporary camp sites (Camp Site 2 and Camp Site 3) will be in use. Quarries and borrow pits will be operated through the construction period but the impacts on the land-use will only be reversed in the long-term if rehabilitation activities are conducted effectively.

V.3.1.2. Impacts on Forestlands

Impacts of the Project (including the campsites, storage areas, quarries, and borrow pits) on the forestlands have been assessed based on the area to be affected and number of trees to be lost in economic, ecological and social/cultural forests.

Loss of Forestlands

The areas of forest within the expropriation corridor to be acquired as part of the Project are listed in Table V.18. A significant portion of the forestland to be affected by the Project is located near Alanya and Manavgat. In total, 1,030.69 hectares of forest area will be impacted by the motorway.

Table V.18. Forest Areas to be Acquired in the Scope of the Project

Regional Directorate	Forestry Management Directorate	Management Sub-directorate	Forest Area Corresponding to the Land Acquistion Corridor (ha)
Antalya Regional Directorate of Forestry	Serik	Akbaş	49.74
	Alanya	Alara	214.64
		Kargı	109.91
	Taşağıl	Çardak	7.22
		Taşağıl	169.93
	Manavgat	Manavgat	172.70
		Naras	70.99
		Şelale	64.08
		Yalçıdibi	157.81
		Murtiçi	13.67
Total			**1,030.69**

In addition to Motorway construction, most of the construction compounds including camp sites and quarries are located on forest lands as summarized previously in above sections. The forest area to be affected by these construction compounds are listed in Table V.19.

Table V.19. Areas and Land Use Information for the Construction Compounds

Location	Location			Description of the Site/Plant	Area (ha)*	Corresponding Main Forest Functions in the Relevant Forest Management Plan
	Province	District	Nearest Neighborhood			
124+300	Antalya	Alanya	İncekum	Concrete Plant-6**	50.15	Economic
				Mechanical Plant-3**		
				Asphalt Plant-3**		
Total					**652.05**	

**The areas presented in the table have been calculated based on the boundaries provided as of 12.02..2025*
*** Concrete Plant 2, Mechanical Plant 1 and Asphalt Plant 1 are located within the same area as the Temporary Camp Site.*

In conclusion, total forest area to be affected by construction compounds and storage sites will be 652,05 ha.

Loss of Trees

Trees corresponding to the permitted road construction areas (road footprint and embankment and fill zones) will be removed and appraised by the relevant Regional Directorate of Forestry in coordination with the KGM and Project Sponsor. In this scope, exact number of trees to be removed is determined by the Regional Directorate after examination of current management plans and field studies.

In calculating the number of trees, the Forest Management Plans prepared by the relevant Forest Management Sub-Directorate, which cover the expropriation corridor and project corridor, were used as a basis. In particular, Table 13 “Tree Type Identification Tables” in these plans was used. Additionally, structures such as tunnels, viaducts, and bridges were included in the tree count estimates based on the worst-case scenario. Therefore, it should be noted that the calculated figures may change during the project implementation phase.

Accordingly, number of trees to be removed in the scope of the Project has been estimated by relevant forestry directorates for the project and is summarized in Table V.20. The figures given in this table has been calculated to cover the trees to be removed from the footprint of the Motorway construction areas including the embankment and fill zone. As can be seen from Table V.20, total number of trees that are lost is 278,915 for Antalya. The calculations were based on the expropriation corridor.

Table V.20. Estimated Number of Trees to be Removed in the Motorway

Forestry Management Directorate / Sub-Directorate	Number of Trees
Serik Forestry Management Directorate	
Akbaş	122
Alanya Forestry Management Directorate	
Alara	81,794
Kargı	68,568
Taşağıl Forestry Management Directorate

Forestry Management Directorate / Sub-Directorate	Number of Trees
Taşağıl	28,387
Manavgat Forestry Management Directorate	
Manavgat	48,226
Naras	287
Şelale	14,619
Yalçıdibi	33.618
Murtiçi	1,816
Total	**278,915**

Table V.21. Trees to be Removed According to their Types

Species Name	Turkish Name	Number of Cut Trees
Pinus brutia	Kızılçam	260,732
Cupressus sempervirens	Servi	10,186
Quercus cerris	Saçlı Meşe	5,020
Santalum album	Sandal	764
Pinus pinea	Fıstıkçamı	559
	Maki	1,654

Secondary Impacts associated with Loss of Forestlands

Besides direct loss of forestlands, as secondary impacts, increased human activity at the construction sites may increase the potential for the start of forest fires. Loss of carbon capture capacity in association with the number of trees lost is discussed in Chapter 10 (“Air Quality and Climate Change”). Socio-economic impacts of the loss of forestlands on local communities are covered in Chapter 14 (“Socio-economic Environment”).

V.3.1.3. Impacts on Agricultural Lands

To meet Project’s land acquisition requirements, agricultural lands located within the expropriation corridor will be expropriated by the responsible agency (KGM). One of the main direct results of the permanent land acquisition to be done in the scope of the Project will be the conversion of productive agricultural lands to built-up lands. Consequently, these lands will be permanently lost for agricultural activities of the local people. Besides the direct loss of lands, following impact types are likely to be encountered by local people on a case-by-case basis:

- Difficulties for local people to ensure access to agricultural lands in cases when the settlement center and the agricultural parcels are separated;
- The fragmentation of agricultural lands by the Motorway, hence difficulties for local people to ensure access between fragmented parts of an agricultural plot; an example to the fragmentation of agricultural lands is shown in Figure V.21.
- Economic losses of local people due to partial expropriation of parcels (e.g. loss of viability for use of the remaining part of the parcel to be expropriated);
- Loss of growing crops and trees as a result of the expropriation of agricultural lands;
- Economic impacts on people, who are not legal owners but rent or use the affected lands.

In addition to loss of lands available for agricultural activities, the Project will results in the severance and fragmentation of the agricultural lands resulting in restrictions in the access to lands by their owners and/or users. An example to the fragmentation of agricultural lands by existing Anatolian Motorway as shown in Figure V.21.

Figure V.21. Example to Fragmentation of Agricultural Lands by Motorways

V.3.1.4. Impacts on Pasture Lands

For the determination of pasturelands located within the expropriation corridor, expropriation plans (as of the date of the analysis) have been reviewed. Parcels registered as pasture are located only in the Uzunlar neighbourhood of the Manavgat district, as listed in Table V.22.
Figure V.22 presents a satellite image of the parcels registered as pasture. A preliminary review of this image suggests that these parcels may not be actively used for grazing purposes. The RAP field surveys confirmed that the registered pasture parcels within the expropriation corridor are not actively used for grazing purposes. According to RAP surveys, in winter, animals are mainly kept in barns and fed stored fodder, or grazed on agricultural fields.

According to CORINE (2018) database results, there is no pasture area to be permanently lost under the Project. According to the results of STATİP (2015) database, GDRS (1993) and socio-economic field interviews, it is concluded that the percentage of pasture land use is very low throughout the Project. Therefore, there will not be a major impact in terms of pastureland.

Table V.22.Pasturelands to be Affected by the Project

District	Neighbourhood	Corresponding Motorway KM	Parcel No	Area		
				Title Deed Area (m^2)	Approximate Area to be Acquired (m^2)	Percent of Area to be Acquired
Manavgat	Uzunlar	106+705.99	101/34	423.17	423.17	100%
		106+741.39	101/35	1,239.43	1,239.43	100%

District	Neighbourhood	Corresponding Motorway KM	Parcel No	Area		
				Title Deed Area (m²)	Approximate Area to be Acquired (m²)	Percent of Area to be Acquired
		106+771.52	101/36	618.88	115.7	18.7%
Total				**2,281.48**	**1,778.3**	

Figure V.22. Parcels registered as Pature and affected by the Project in Uzunlar neighbourhood

V.3.1.5. Impacts of Quarry and Borrow Pits

Land preparation (i.e., vegetation and top-soil clearing) and excavation activities to be conducted at the quarry and borrow pits will also result in local changes in the land use patterns. **Error! Reference source not found.** summarizes the area to be affected by each quarry and borrow pit.

Table V.23.Area to be Affected by Quarry/Material Borrow Site Operations

Location	Location			Description of the Site/Plant	Area (ha)*	Type of Land Use	Corresponding Main Forest Functions in the Relevant Forest Management Plan
	Province	District	Nearest Neighborhood				
Km 53+800	Antalya	Serik	Sarıabalı	Sarıabalı Borrow Pit (AO-1)	24.69	Forest	Economic, Ecological, Sociocultural
Km 56+500	Antalya	Manavgat	Çakış	Çakış Quarry (TOY-4a)	24.21	Forest	Economic, Ecological,
Km 58+500	Antalya	Manavgat	Sağrın, Taşağıl	Kuruçay Quarry	20.17	Forest	Economic
Km 84+500	Antalya	Manavgat	Sarılar	Dikmen Borrow Pit (AO-2)	19.91	Forest, Agricultural	
Km 104+750	Antalya	Akseki	Güçlüköy	Bademliyar Quarry (TO-2)	13.66	Forest	Economic, Ecological,

Total					**175.65**		

*The areas presented in the table have been calculated based on the boundaries provided as of 12.02.2025

V.3.1.6. Impacts of Excavated Material Storage Sites

As the excavated material storage sites will be permanent Project components, land use corresponding to these sites will change permanently as a result of the Project. Table V.24**Error! Reference source not found.** summarizes the area to be affected by excavated material storage site.

Table V.24.Area to be Affected by Excavated Material Storage Sites

Location	Location			Description of the Site/Plant	Area (ha)*	Type of Land Use	Corresponding Main Forest Functions in the Relevant Forest Management Plan
	Province	District	Nearest Neighborhood				
52+544	Antalya	Serik	Sarıabalı	Storage-2	5.93	Forest	Economic
59+580	Antalya	Manavgat	Çakış	Storage-3	13.56	Forest	Economic, Ecological
61+500	Antalya	Manavgat	Taşağıl	Storage-6	17.70	Forest	Economic, Ecological

Total					**319.01**		

**The areas presented in the table have been calculated based on the boundaries provided as of 12.02.2025*

V.3.2. Operation Phase

In the operation phase, the activities will not involve any additional physical interaction thus no additional impact on land use is foreseen. The impacts related with habitat fragmentation/alteration and socio-economic impacts due to land acquisition will be permanent thus this may result in changes (positive or negative) in the existing socio-economic conditions of some of the potentially affected households in the long term. Rehabilitation measures will be taken at the temporary Project components, including three campsites, two borrow pits and one Project Sponsor-operated quarry, following the completion of construction activities. The restoration of vegetation at these sites during the operation phase is expected to result in positive impacts on land use.

V.3.2.1. Future Urban Development Potential

The future development potential of the Project area has been analyzed based on the 1/100.0000 scale Antalya-Burdur-Isparta Planning Region Environmental Plan.

In addition to the direct physical impacts of the activities on the lands and socio-economic dimensions of the land acquisition, transportation projects possibly trigger further land developments in the vicinity of route, especially when the Motorway provide access to previously less accessible areas. Increased access to land raises its potential for development (e.g. residential, industrial, tourism) and need for additional transportation services. This in turn, results in changes of the land use patterns over a period of time (Oruonye, E.D., 2014).

Given the tourism priority of the Antalya-Alanya region, the infrastructural development provided by the Antalya-Alanya Motorway Project is expected to significantly boost tourism investments. Improving the accessibility to the region's cultural sites and natural attractions will possibly lead to the expansion of tourism facilities such as hotels, resorts, and recreational areas. This development may subsequently drive residential and commercial growth to support the increasing number of tourists and tourism-related businesses.

Moreover, while the region may also see some industrial growth, the primary impact of the Motorway is anticipated to be in enhancing the tourism sector, which could bring substantial social, cultural, and economic benefits. Consequently, the development and operation of the Motorway are expected to result in notable changes in existing land use patterns, increased population growth, and a higher demand for residential, commercial, and infrastructural development in the region, all centered on the burgeoning tourism industry.

V.4. Mitigation Measures

The route selection process for the Project has considered sensitivities related with the land use patterns and their socio-economic dimensions. As explained in details in Chapter 18 ("Analysis of Alternatives"), the Project has aimed to establish a balance between the crossing of ecologically sensitive forest areas and impact on agricultural lands to avoid intolerable ecological and socio-economic impacts associated with Project land acquisition. In the following sections, measures to be taken to minimize and/or mitigate direct impacts on the land use are described for the land preparation, construction and operation phases. It should be noted that implementation of the expropriation works and permitting process for the forests and public lands are under the responsibility of KGM as the administrative authority.

Measures to be taken against potential socio-economic impacts that would be associated with land use changes will further be evaluated in Chapter 14 ("Socio-economic Environment"). Measures to be taken to mitigate impacts on habitats and wildlife due to loss of forestlands are covered in Chapter 9 ("Ecology and Biodiversity").

V.4.1. Land Preparation and Construction Phase

Land use rights for the lands/parcels corresponding to Project components, including the construction campsites, storage areas, quarry and borrow pits will be acquired either permanently or temporarily. Acquisition of land use rights for those lands/parcels located within the expropriation corridor has been/will be done by the KGM in accordance with the national legislation. Following the acquisition of land use rights, these lands will be allocated to the Project In this respect;

- Privately-owned lands have been/will be acquired in line with the relevant provisions of the Turkish Expropriation Law;
- Forestry permits have been/will be obtained from the Forestry authorities in line with the Forestry Law;
- For the state-owned lands including treasury lands and pasture lands, applications will be done to acquire easement rights.

KGM will complete the process for the allocation of the private lands under the property of Treasury and the state-owned lands that are required for the Project and allocate those lands to the Project Sponsor for their use during the BOT contract duration. In this respect, free of any charge, easement rights for the benefit of Project Sponsor will be constituted for the private lands under the property of Treasury and usage rights for the use of state-owned lands will be provided for the duration of the contract. At the end of the contract duration, lands under the property of Treasury and the state-owned lands will be transferred to KGM free from any debt or commitment and in a well-maintained, operating, in-service condition, without any charge.

V.4.1.1. Construction Sites

In the scope of road construction works, the following measures will be taken to avoid and/or minimize the cases of unauthorized intrusion of construction machinery onto adjacent privately-owned lands that are out of the expropriation corridor:

- Borders of the construction areas and expropriation corridor will be identified by suitable markings.
- Construction personnel will be trained to stay within the border of the construction areas and expropriation corridor.
- For exceptional cases when the privately-owned land has to be used but the expropriation or court processes have not been finalized yet, no work will be started until bilateral agreements are settled and official consent letters are taken from the legal owners. In such cases, official commitment letters will be provided to legal owners by the Project Sponsor regarding the scope of works and compensation of probable damages and the works will be conducted in accordance with those consent and commitment letters.
- Grievance Mechanism will be established and utilized for the Project (see SEP for further details of the mechanism). If complaints related with unauthorized use of privately-owned lands, damages on adjacent lands, etc. are received through Project's Grievance Mechanism, evaluation/inquiry will be conducted on a case-by-case and where necessary, corrective actions will be planned and implemented.
- In accordance with KGM's technical specifications, in case of any direct or indirect damage on state or personal property as a result of the activities of the Project contractor or sub-contractors, Project Sponsor will ensure that relevant corrective measures (e.g. repair, maintenance, rebuilding, restoration, etc.) are implemented at its own cost in line with the instructions of the KGM or other related governmental agencies.

Construction campsites, concrete/asphalt/mechanical plants and borrow pits will be used for a temporary period throughout the construction phase. Once the construction activities are completed, following measures will be taken for the rehabilitation of sites:

- Initially above-ground construction compounds including the plants/facilities, prefabricated buildings/houses, relevant infrastructure and installations, etc. of no beneficial use will be dismantled and removed in accordance with the national and international legislation.
- Any storage tank and pipes will be taken out of operation and fully emptied. Liquid wastes will be removed in accordance with the national and international legislation.
- Affected lands at the construction campsites and service roads will be graded and appropriately rehabilitated to acceptable uses.
- Any void area formed as a result of demolition works will be filled with suitable soil or other materials that are compatible with the natural topography and local ground conditions.
- Topsoil stripped prior to the installation of construction compounds will be reapplied and landscaping activities will be conducted in conformity with the surrounding land uses. Lands that will not be restored for a specific community use will be seeded and revegetated with native species.

V.4.1.2. Forestlands

The legislation related to forest areas, their protection and utilization for public benefit is composed of laws and regulations that are based on the constitution of Türkiye. The central administrative authority is the Ministry of Agriculture and Forestry. The relevant agency within Ministry of Agriculture and Forestry is the General Directorate of Forestry, which itself has regional directorates (including Antalya Regional Directorate) in the country and management directorates and management sub-directorates in those regions. These directorates are responsible for protecting forestry and forestry resources

against negative impacts, and developing and managing forestry and forestry resources in a sustainable way.

Within this framework, forestlands corresponding to the Project components are under the authority of the Ministry of Agriculture and Forestry. In accordance with the Forest Law and associated regulations, relevant forestry permits have to be obtained by the KGM from the Ministry of Agriculture and Forestry, for the construction of Project components on forestlands.

Once the forestry permits are obtained, all the works including tree marking, felling, logging, chipping, removal and appraisal (selling, etc.) is performed by the General Directorate of Forestry and its Regional Directorates during the period between permit issuance and delivery of the land to the KGM.

For the forest lands to be used in the scope of the Project, forestry permit applications have been/are being submitted by KGM to related Forestry authorities in accordance with the Forest Law. Measures that have been taken to minimize the impact on forests and that will be taken in the course of the Project to compensate unavoidable impacts are described in the following paragraphs.

Minimization of the Loss of Forestlands

One of the main aims of the Project is to minimize the impact on forestlands to the greatest extent possible. Accordingly, the avoidance of forest areas was one of the key criteria considered during the route selection process. Where forest crossings were unavoidable, viaducts, bridges and tunnels were incorporated into the design to reduce direct ground-level disturbance and preserve underlying habitats.

Complementary measures such as erosion control, preservation of remaining vegetation, and long-term forest recovery monitoring will also support the minimization of forestland degradation throughout the construction and operational phases.

Afforestation

Following the completion of construction activities, measures will be taken to compensate (afforestation/reforestation) the lost forest assets at alternative locations to be determined by the Forestry authorities. In this scope, Project Sponsor will aim to compensate the loss of forest lands by planting trees at alternative areas on a voluntary basis. In the case of voluntary afforestation applications, afforestation is carried out in any region of Türkiye in line with the directions of the Forestry authorities. Project Sponsor will make the reasonable efforts to cooperate with the Forestry authorities and if approved by the Forestry authorities, afforestation activities in the scope of the Project will be conducted primarily at suitable locations in the region to adequately compensate the lost forest functions. Afforestation areas will be under the authority of relevant Forestry authorities, which decides for the specific tree species to be planted in each region, depending on the forest habitats and specific requirements of that region. These requirements are determined yearly and are specified on that year's afforestation plans of the Regional Directorate. The relevant Forestry authorities will be informed about the outcomes of the ecology studies done in the scope of the ESIA studies and the proposals for the plant species in consideration of the local ecological sensitivities.

Implementation of the Afforestation Plan will be initiated in the construction phase and may continue through the initial phases of the operation period. In order to compensate for the loss of forest assets in the Project Area, it is advised that the planting would be five times of the number of trees to be removed from the Project Area.

Response to Forest Fires

Regarding potential forest fires, the following measures will be taken in accordance with good site practices and KGM's technical specifications:

- Project Sponsor will require all contractor and sub-contractor personnel to take necessary measures to avoid forest fires and immediately respond to any fire event that could not be avoided by measures taken.
- Project Sponsor will cooperate with relevant governmental agencies to make all the reasonable effort in responding forest fires.
- Project personnel will be trained to immediately inform forestry authorities about the location and scale of any fire incident.
- Adequate number and amount of firefighting equipment will be provided at construction sites. Fire-fighting equipment will not be obstructed. On the field, there will be always proper trained personnel and units who can use fire-fight equipment efficiently.
- Proper fire extinguishers will be kept ready at site where hot/welding works will be performed.
- The operability's of fire-fight equipment will check regularly.
- Construction sites and work areas, which are prone to fire incidents, will be determined and accordingly, locations where smoking is not dangerous will be specified and smoking will only be allowed at these locations. Throwing cigarette butts on the floor will be prevented by means of relevant applications/sanctions (i.e. trainings, placing ashtrays to the locations where smoking is allowed within the construction site, etc.)
- Within the scope of the training program to be given to the personnel, basic field rules for fire protection will be explained, awareness on fire hazard will be raised and personal responsibilities will be defined. Against fire incidents that cannot be prevented by taking relevant measures, personnel will be trained on emergency procedures and use of emergency response equipment.
- Not all fires (e.g. forest fires caused by energy transmission line) will be responded with water. To stop a fire caused by electric current, sufficient amount of dry-type extinguishers will also be kept available at the site. Electric current may be cut off before responding to fire, if deemed necessary.

V.4.1.3. Agricultural Lands

Expropriation of privately-owned agricultural lands will be done by KGM in accordance with the relevant provisions of the Expropriation Law. In the accordance with Turkish Expropriation Law, if the land portion remaining from expropriation would not be viable anymore, eligible persons have the right to request the expropriation of the entire parcel (application has to be in line with the requirements of the Law) including the remaining portion, even if this portion is out of the expropriation corridor. Relevant article of the Law is provided below:

Article 12: Partial Expropriation Where only part of a property is to be expropriated its value is estimated in accordance with Article 12 of the Expropriation Law as follows: a. In cases where no change occurs in the value of the non-expropriated part due to the expropriation, the value of the expropriated part shall be determined in proportion to the total value of the whole property in accordance with Article 11 of the Expropriation Law.

b. If a decrease in the value of the non-expropriated part occurs as a result of expropriation, this loss is estimated and added to the expropriation value of the expropriated part as defined in the relevant paragraph of the Law.

c. If an increase in the value of the non-expropriated part occurs as a result of expropriation, this increase is estimated and subtracted from the value of the expropriated part as defined in the relevant paragraph of the Law.

d. The decreased and increased amounts stated in relevant paragraphs of the Law are determined according to the valuation method under Article 11 of the Expropriation Law.

e. When the remaining part of the property after expropriation remains suitable for use in accordance with the zoning legislation, the expenses and costs for reinstatement of any buildings, surrounding walls, sewerage, water, electricity and gas lines that are damaged shall be determined and added to the expropriation value.

f. When the remaining part of the property is no longer suitable for use, and the expropriation decision is not challenged in the courts, the owner may apply in writing within 30 days of the date of notification of the expropriation decision, for the remaining part also to be expropriated.

In accordance with Expropriation Law, standing crops, trees, irrigation structures, walls, fences, etc. will be considered in the valuation process and the compensations will be provided by responsible agency (in this case KGM) to cover the associated losses.

- Several underpasses and culverts have been included in the design to ensure access of local people to agricultural lands. These underpasses and culverts will ensure sufficient dimensions for the passage of harvesters, vehicles, etc. where required. Detailed lists of underpasses and culverts planned in the Project are provided in Chapter 3 (“Project Description”).
- Access roads will be constructed adjacent to the Motorway near agricultural areas/zones to provide access to agricultural lands, if/where necessary.
- Legitimate requests of local people regarding the avoidance and/or minimization of the restriction of access between their settlement areas and agricultural lands will be considered by the Project Sponsor’s design team and feasible solutions will be developed and implemented, where possible.

V.4.1.4. Pasture Lands

For the pasturelands that will be separated by the Motorway (fragmentation of land), impacts on the public users of the pasturelands will be mitigated by ensuring access between severed lands by using the culverts.

V.4.1.5. Quarry and Borrow Pits

A production license is required when state institutions and organizations plan to source construction raw materials from forest areas. Based on this permit, permission for all operations and construction associated with this activity is regulated by Implementing Regulation of the 16th Article of the Forest Law, production license will be obtained for the quarry and borrow pits to be used. Measures to be taken at the quarry and borrow pits are described below:

- Borders of the quarry and borrow pits will be identified by using proper methods (i.e. fencing, etc.) and material extraction activities will be conducted within these borders.
- Topsoil management measures (see Chapter 6 “Topography, Soils and Geology”) to be taken at Motorway construction sites will be applied at the quarry and borrow pits.

- Appropriate low-impact extraction methods that would result in final site contours supportive of habitat restoration principles and final land use will be selected wherever feasible.
- Preference for extraction will be given to thicker deposits as far as possible and as reasonable to land use changes and consequent loss of soil.
- Borrow pits will be reclaimed immediately after the completion of extraction activities. Rehabilitated lands will conform to acceptable uses consistent with local and regional land use plans.
- During reinstatement, affected land will be graded and appropriately prepared prior to the reapplication of soil layers that would sustain vegetative regrowth.

V.4.2. Operation Phase

As no additional direct physical impact on land use is anticipated in the operation phase, mitigation measures to be taken in this phase will be mainly limited with the afforestation activities that would continue in line with the commitments of the Project Sponsor and guidance of the relevant Forestry authorities. On the other hand, in order to minimize the unplanned development potential and meet the infrastructural needs of the potentially growing populations adequately, regional and local planning authorities and administrations should duly assess the future development potential of the region where Antalya-Alanya Motorway Project and other large-scale infrastructure projects are to be implemented and develop relevant measures.

V.5. Summary of Assessment and Residual Impacts

Table V.25 provides a summary of the land use assessments, highlighting the significance of identified impacts both before and after the implementation of mitigation measures. As can be seen from the Table V.25, in general, potential impacts on the forestlands, agricultural lands, etc. are anticipated to be reduced to low levels in the long-run with effective implementation of mitigation measures, with the exceptions of (i) forests having ecological functions for which the residual impacts have been evaluated as medium due to their importance; (ii) agricultural lands that are suitable for soil cultivation for which the residual impacts have been evaluated as high or medium depending on the land use capability class of the soils to be affected; (iii) pasturelands with Class I-V land use capability class for which the residual impacts have been evaluated as medium. Regional land use character would also change significantly (may be beneficial or adverse depending on the planning measures to be taken by the authorities) in the long-run.

It should be also noted that a certain period of time (from months to years) will be needed to ensure that the residual impacts are adequately mitigated to acceptable levels as measures such as rehabilitation of temporary Project sites or afforestation take time to show their effectiveness. Additionally, the Project may trigger future tourism, urban and industrial development in certain locations along the route. The residual impact of the development may be beneficial or adverse for different receptors, in any case being of high significance. The control of the development is under the authority and responsibility of the local and regional administrations and the stress to be put on the forests and agricultural areas surrounding the settlements has to be well balanced to avoid further significant losses of these land uses.

Table V.25.Summary of the Land Use Assessments

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Land Preparation and Construction Phase

**These forest areas and related impact assessments will be updated after the Forest Management Plan and Forest Stand Map are examine*

VI. TOPOGRAPHY, SOILS, AND GEOLOGY

This chapter identifies existing topographical, soil, and geological conditions along the Motorway route and assesses the potential impacts associated with these aspects. Measures proposed for the mitigation of the potential impacts and the residual impacts are also described in this chapter for the following main types of impacts:

- Permanent changes in the existing topographical features;
- Soil disturbance due to earthworks, construction activities, and materials extraction;
- Initiation and/or acceleration of soil erosion process;
- Risk of soil contamination due to accidental spills, leakage and improper waste management;
- Risks associated with the handling of existing contaminated lands;
- Geological and geotechnical risks.

VI.1. Assessment Methodology and Data Sources

Soil properties along the Motorway route will be defined for a 400 m study corridor (6,856 ha). In this context, major soil groups and erosion levels of these soils along the Motorway have been determined based on the Land Use and Soil Database prepared by the former General Directorate of Rural Services for Antalya (1993). In addition, the "Coordination of Information on the Environmental (CORINE) Land Cover Classification" (2018) database is also used to determine land use characteristics. A soil sampling and analysis program was carried out to determine the quality of representative soil samples at selected locations along the Motorway route. Geological-geotechnical investigation reports and readily available internet resources were utilized to characterize the fundamental geological and geotechnical conditions in the Project area.

The data sources to be used in this context are listed below:

- Land Use Database of the former General Directorate of Rural Services (GDRS; Antalya, 1993),
- Coordination of Environmental Information (CORINE) Land Cover (2018),
- Laboratory analysis results for soil samples collected in the Project area,
- Geological-geotechnical survey reports.

Significance Criteria

The significance criteria for the impacts on topography, soils, and geology will be determined as high, medium, or low, based on the evaluation of the magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter 4 (“ESIA Methodology”) will be used for the determination of the magnitude of impact on the land use components, while sensitivity/value criteria to be used in the scope of impact assessment are summarized in Table VI.1. A detailed explanation of the sensitivity components for each ecosystem component is provided in the following “Baseline Conditions” section.

Table VI.1. Criteria for Sensitivity/Value of Resource/Receptor

Ecosystem Component	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Topography	Unique topographical structure	Natural topograpghy	Already disturbed topograpghy
Soil- Erosion	Soil with severe (Level 3) and very severe (Level 4) erosion potential according to GDRS Database	Soil with moderate (Level 2) erosion potential according to GDRS Database	Soils with none or very little (low) erosion potential (Level 1)
Soil - Contamination	Soils corresponding to lands classified by CORINE Land Cover Database as “Arable Land”, “Permanent Crops”, “Pastures” and Heterogenous Agricultural Areas” (under Agricultural Areas) and Forests (under Forests and Semi-natural Areas)	Soils corresponding to lands classified by CORINE Land Cover Database as “Artifical, Non-agricultural and Vegetated Areas” (under Artificial Surfaces) and “Shrub and/or Herbaceous Vegetation Associations” (under Forests and Semi-natural Areas)	Soils corresponding to lands classified by CORINE Land Cover Database as “Urban Fabric”, “Industrial, Commericial and Transport”, “Mine, Dump and Construction Sites” (under Artificial Surfaces)
Soil - Topsoil	Agricultural areas, where topsoil thickness is 20-30 cm	Forest areas, where topsoil thickness is 10-20 cm	Pastures/Steppe, where topsoil thickness is 5-10 cm
Geology - Landslides	Active landslide areas	Former/Ancient landslide areas	Areas with no landslide history
Geological Features	Sites with unique geological sites and features of scientific or social/cultural importance		Sites with no unique geological sites and features of scientific or social/cultural importance
Seismicity	1st Degree Earthquake Zones according to relevant Earthquake Zoning Maps	2nd Degree Earthquake Zones according to relevant Earthquake Zoning Maps	3rd Degree Earthquake Zones according to relevant Earthquake Zoning Maps

VI.2. Baseline Conditions

A detailed assessment of the existing topographic, soil and geological conditions along the Motorway route is presented in this subsection to understand the current conditions of the Project Area prior to the commencement of the Project.

VI.2.1. Topography and Soils

VI.2.2. Topographical Conditions

Topographical conditions combine terrain features, hills, slopes and elevation levels along the Motorway route. The distribution of slopes along the Project area is given in Table VI.2. According to the conducted studies, steep/very steep slopes of over 20% cover 49% of the Motorway while flat areas with less than 10% slopes comprise 26% of the route. Elevation and slope maps for the area where the project will be implemented are presented in
Figure VI.1.

Table VI.2. Slope Groups within the Study Corridor of the Project

Slope (%)	Area (m^2)	Area (ha)	Percent (%)
0 - 2 %	10,202,218.30	1,020.22	14.88
3 - 5 %	10,419,835.95	1,041.98	15.20
6 - 10 %	11,242,176.98	1,124.22	16.40
11 - 20 %	14,007,002.44	1,400.70	20.43
21 - 30 %	8,426,578.59	842.66	12.29
30+ %	14,263,514,51	1,426.35	20.80
Total	**68,561,326.77**	**6,856.13**	**100.00**

VI.2.2.1. Soil Characteristics

Soil conditions along the Motorway route will be described based on the soil groups, erosion levels, and the content of the soils that represent productivity. Slope conditions are provided under the previous “Topographical Conditions” subsection, while land use capabilities are described in Chapter 5 (“Land Use and Property”).

Soil Groups

Soil groups corresponding to the study corridor have been described based on the land use and soil database of the former Turkish General Directorate for Rural Services (GDRS) published for Antalya province in 1993. The results of the analyses done in this scope are provided in Table VI.4. Maps of soil groups within the study corridor are presented in

Figure VI.1 through
Figure VI.5.

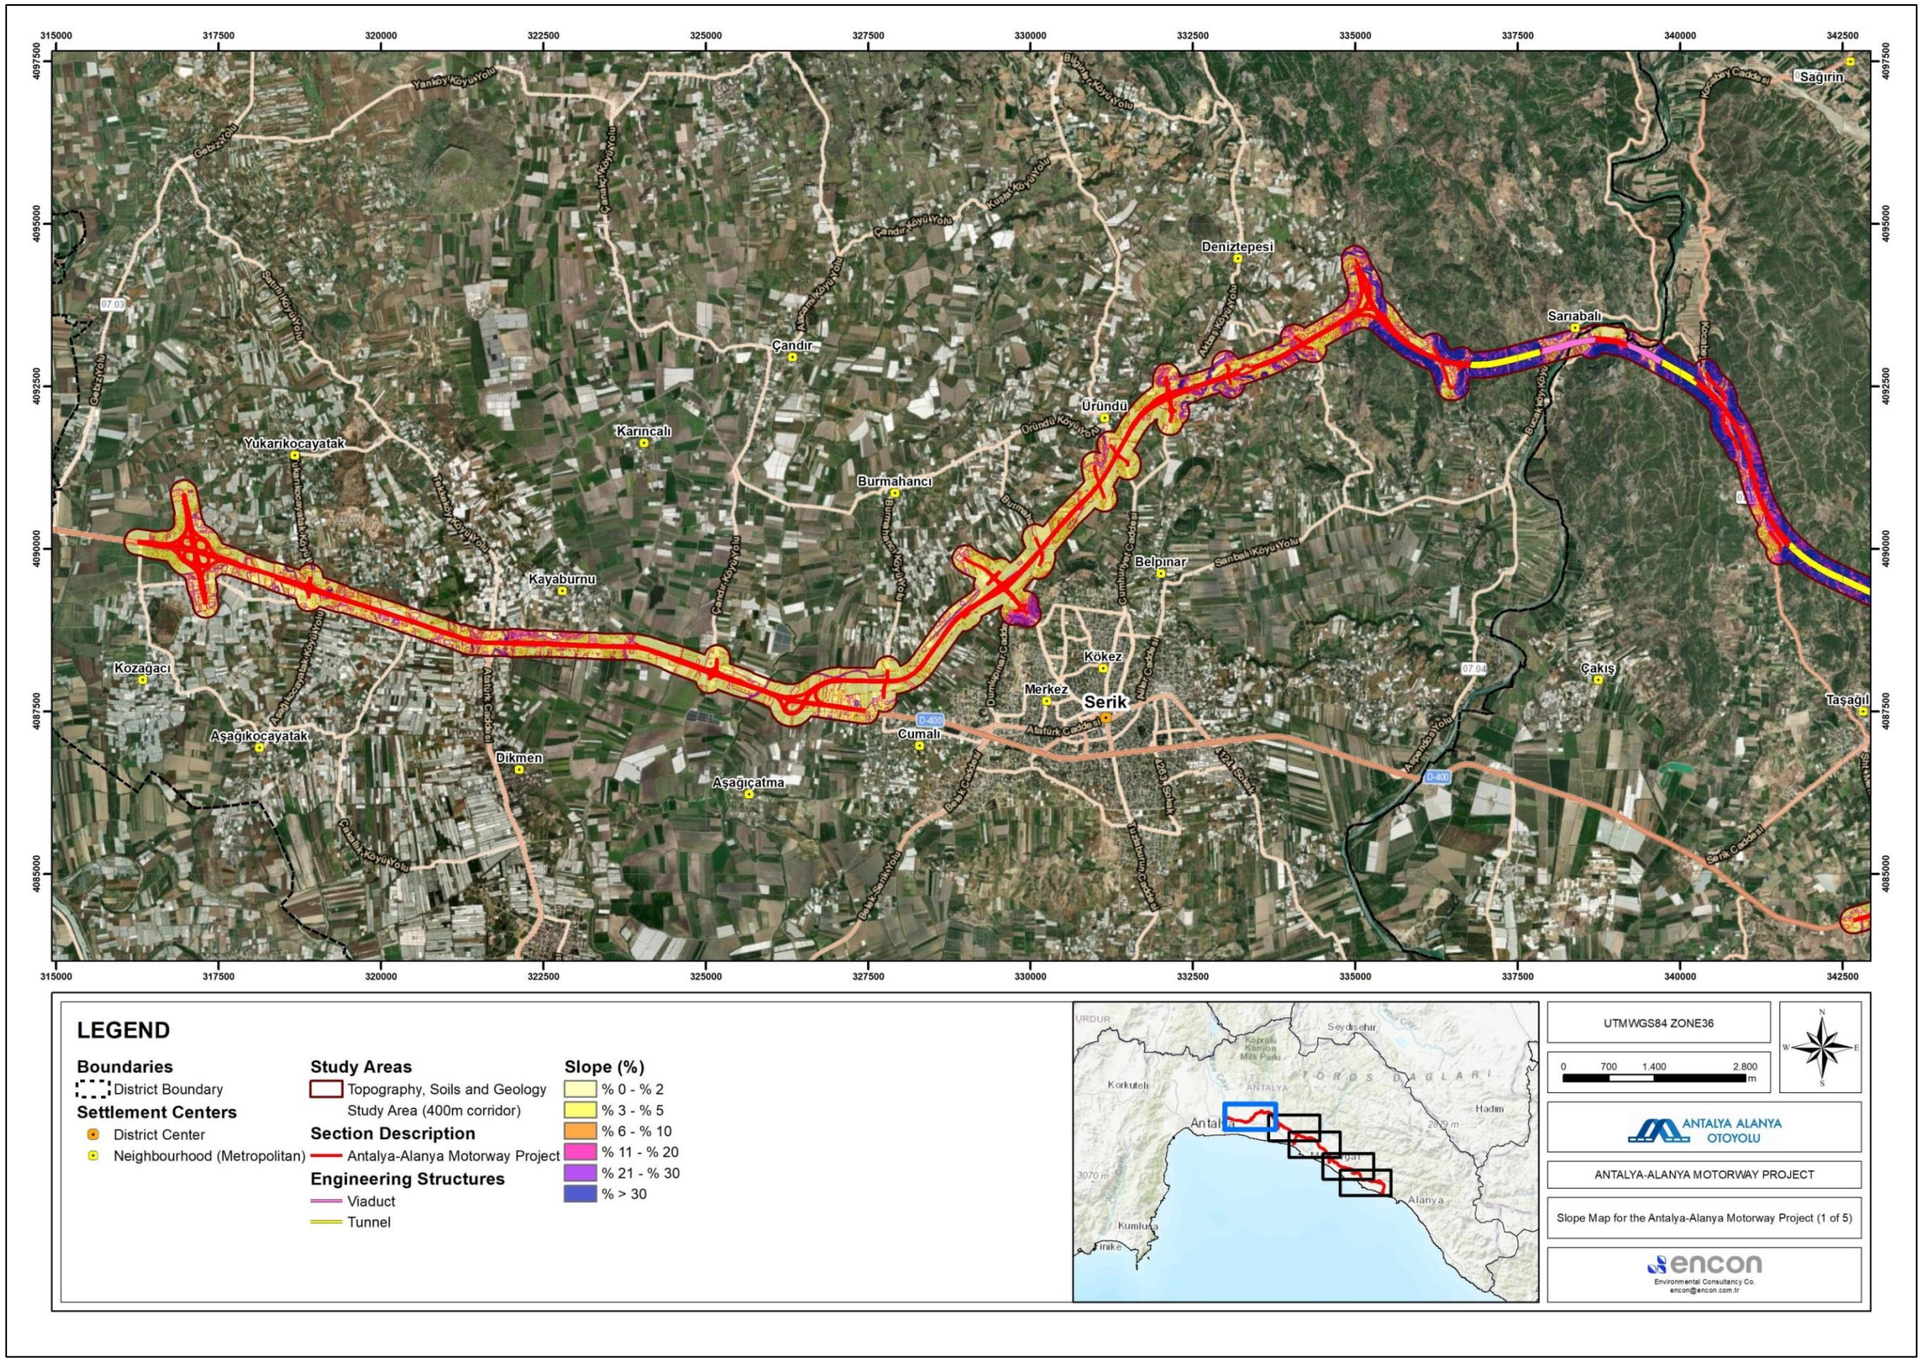

Figure VI.1. Slope Maps of the Project-1

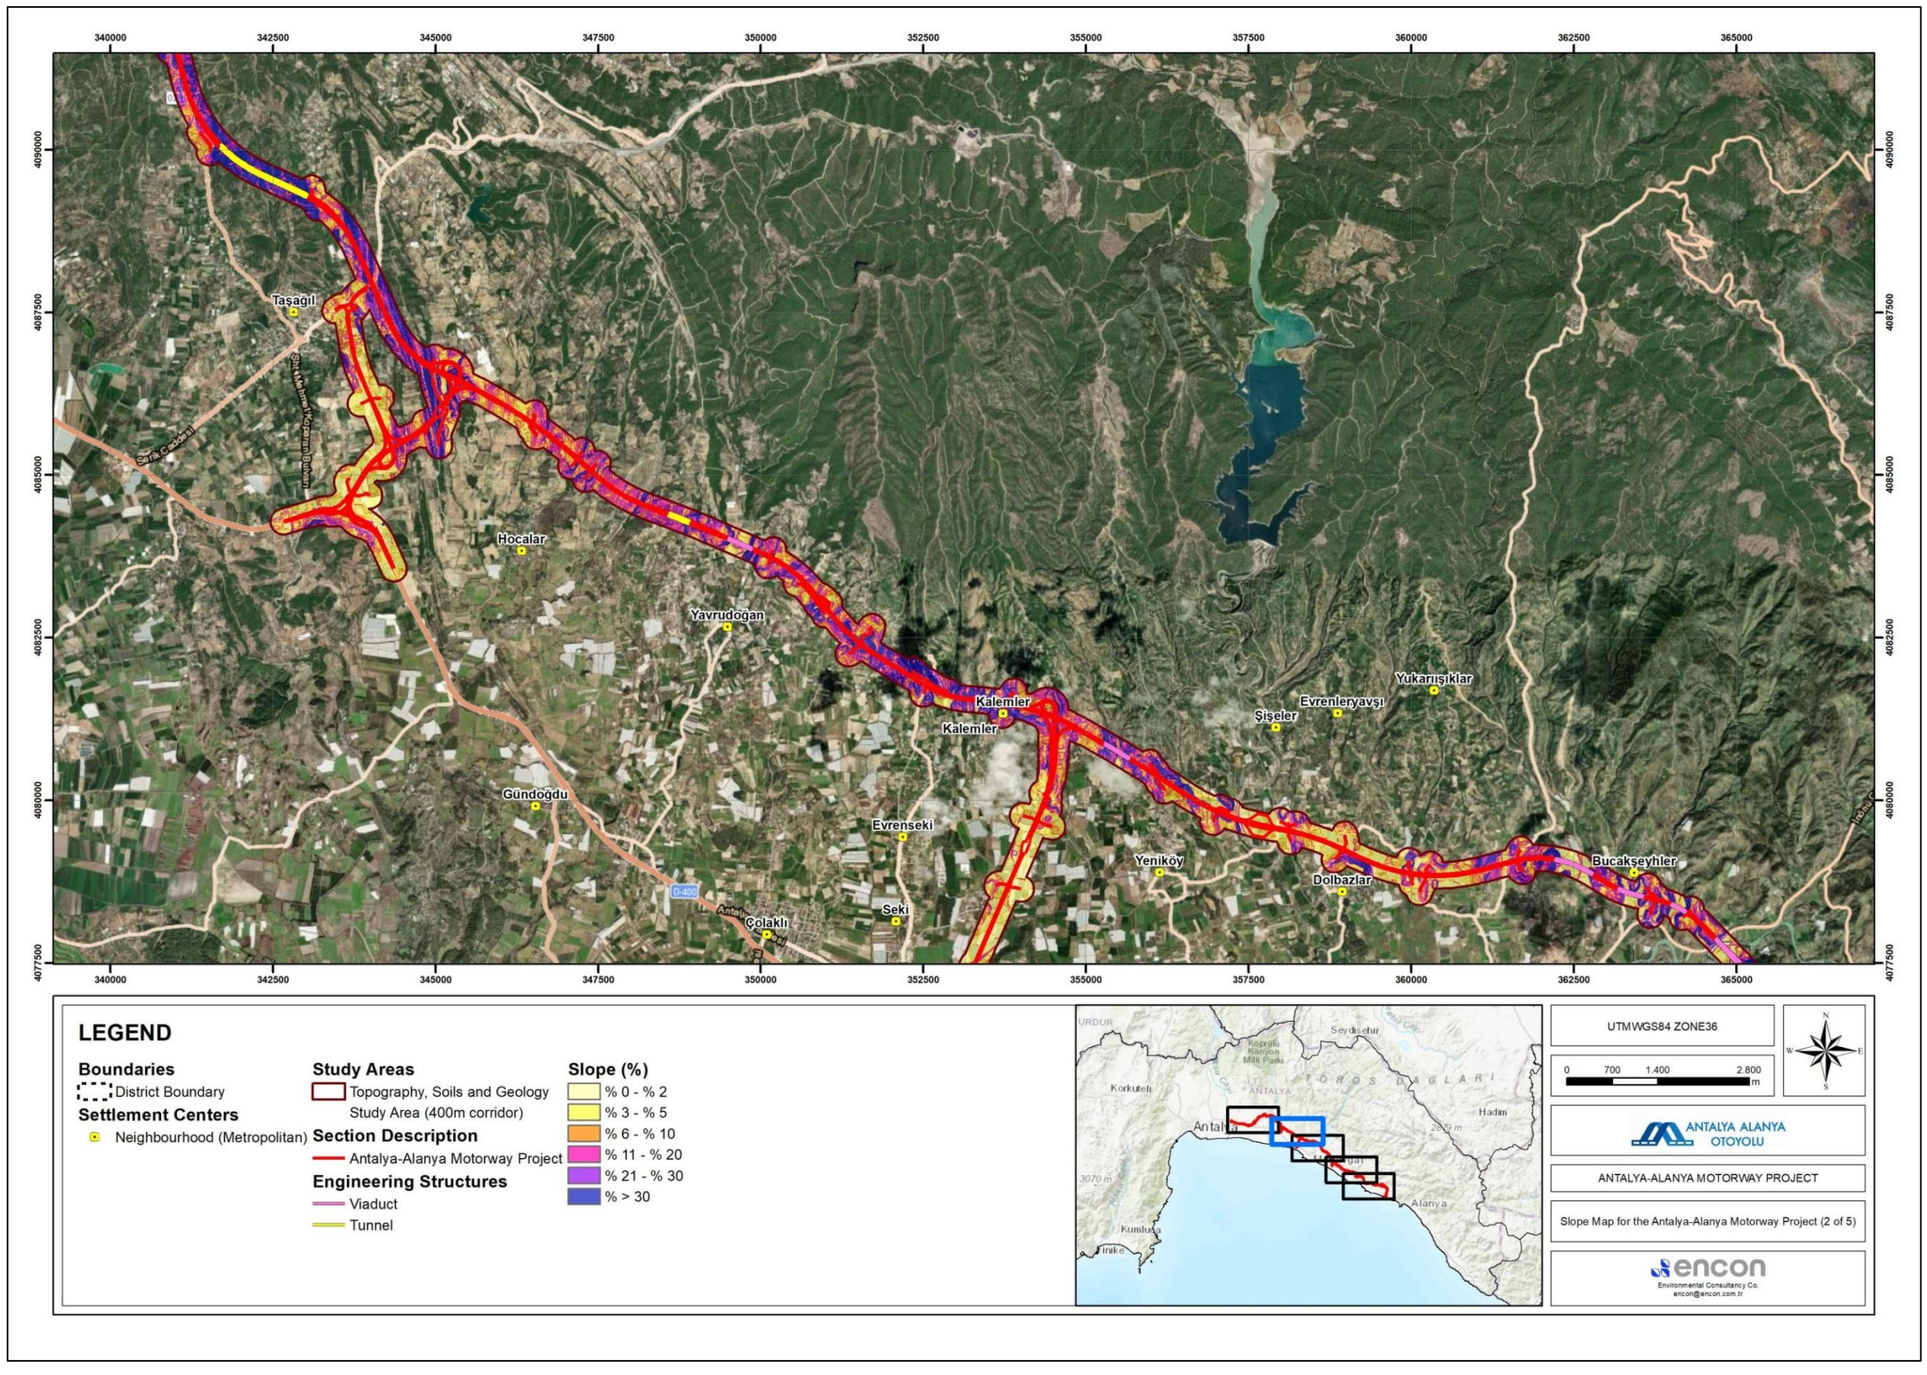

Figure VI.2. Slope Maps of the Project-2

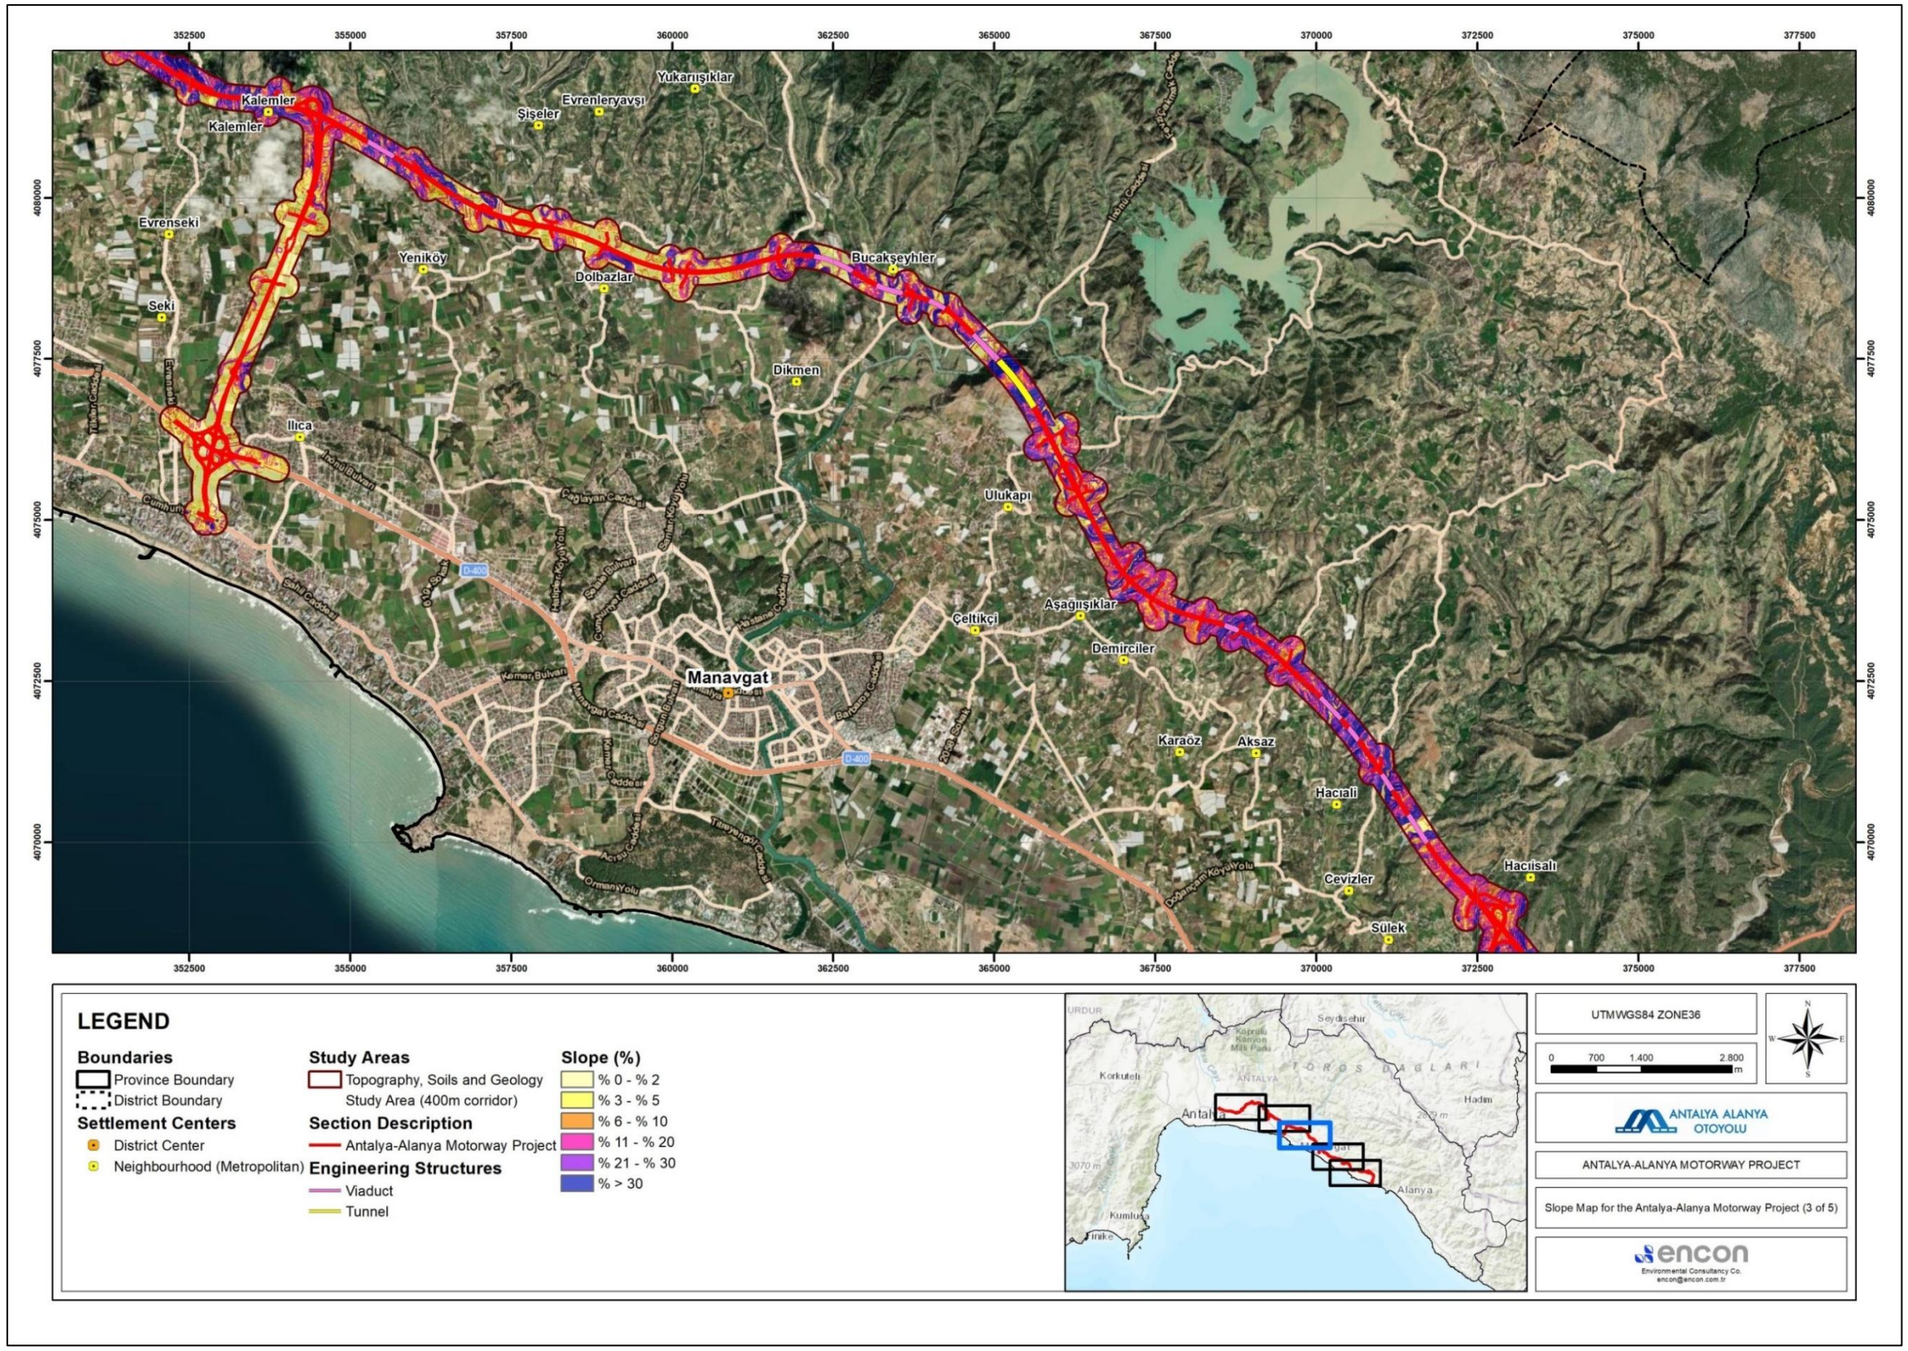

Figure VI.3. Slope Maps of the Project-3

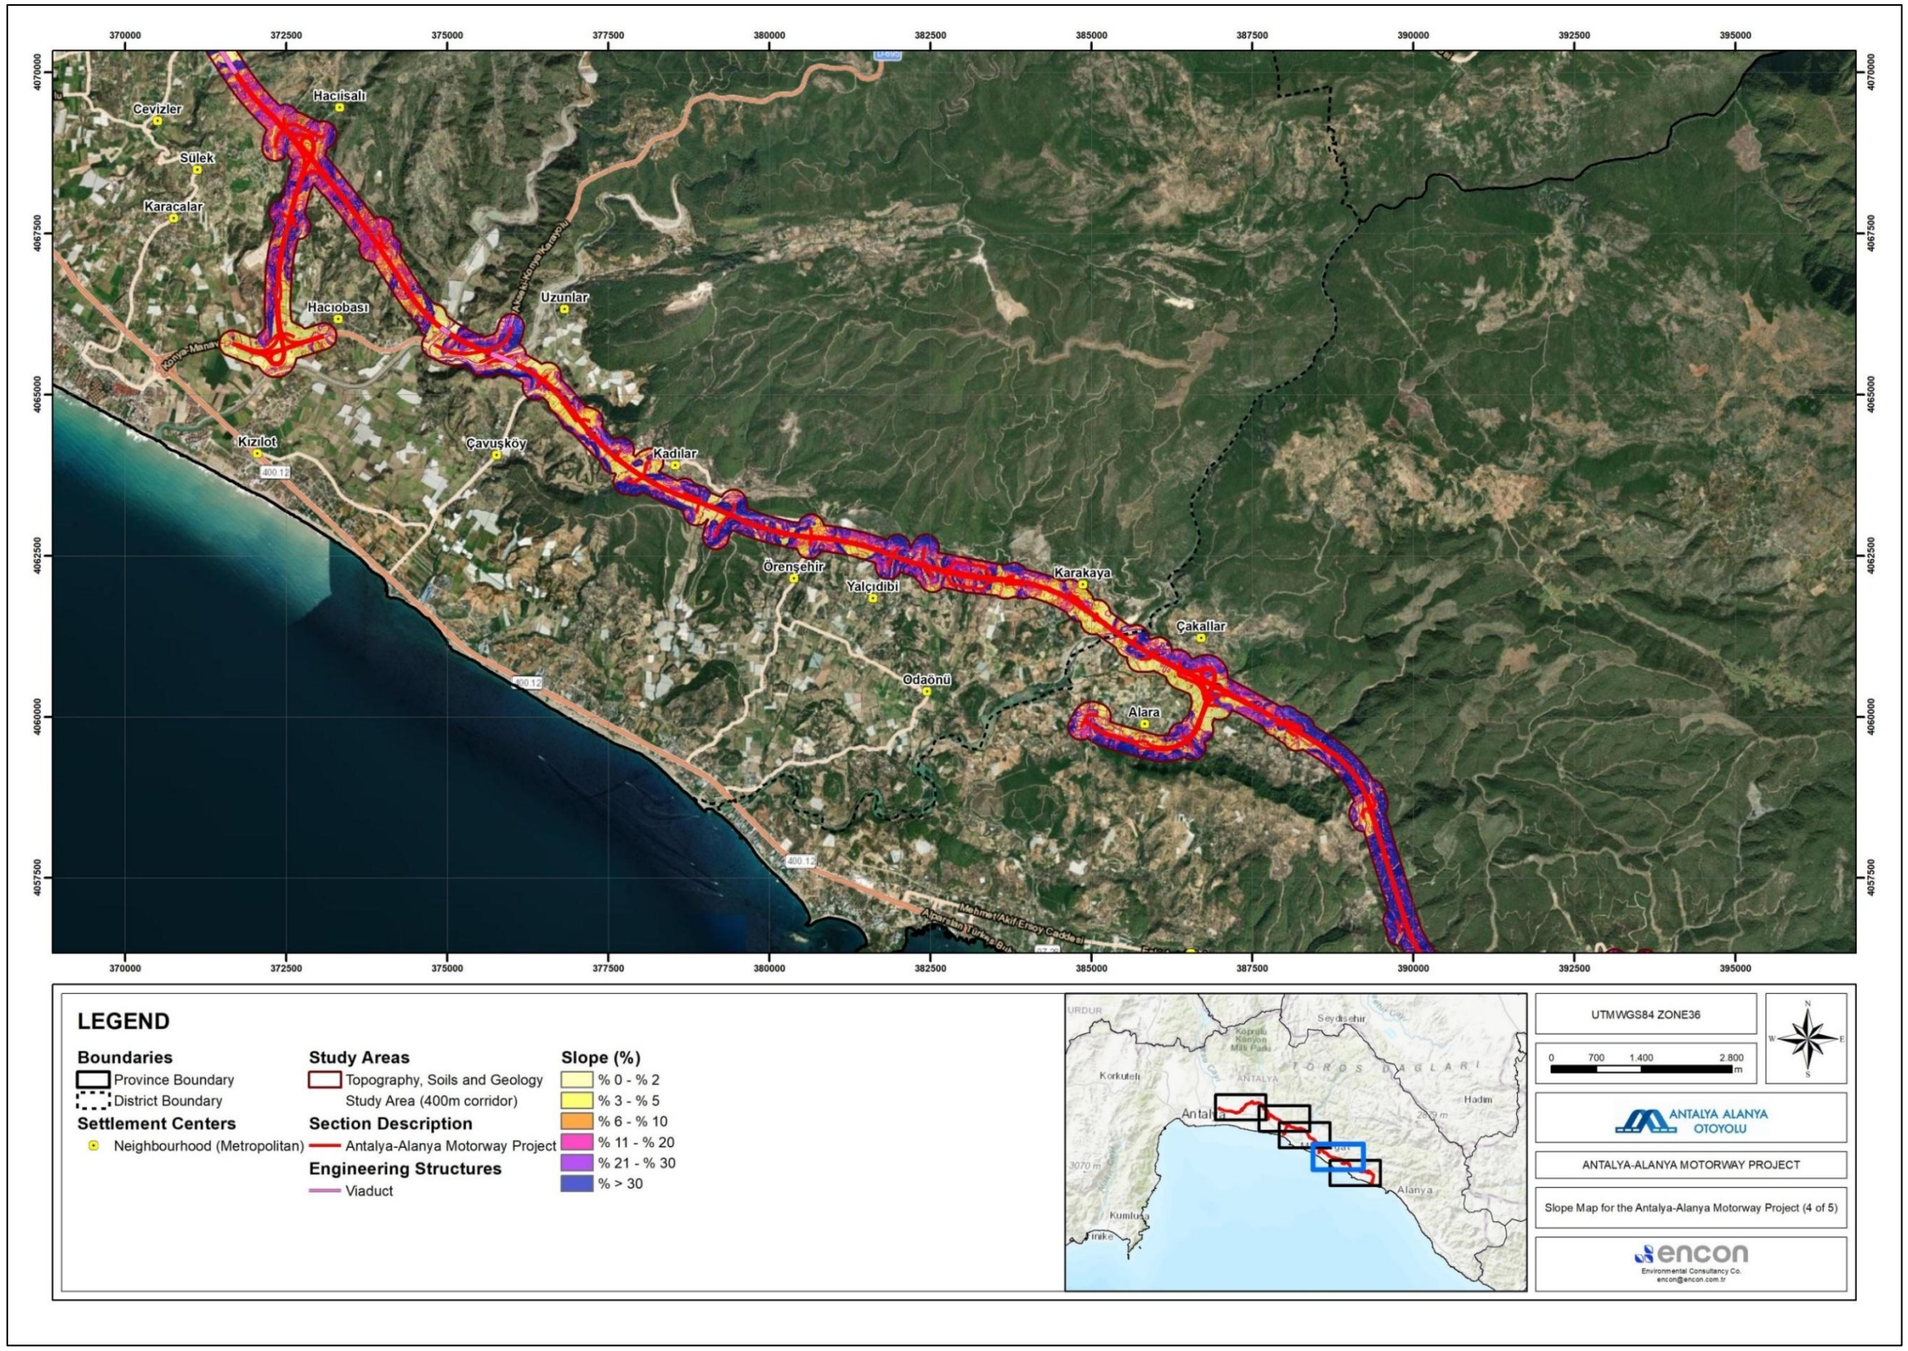

Figure VI.4. Slope Maps of the Project-4

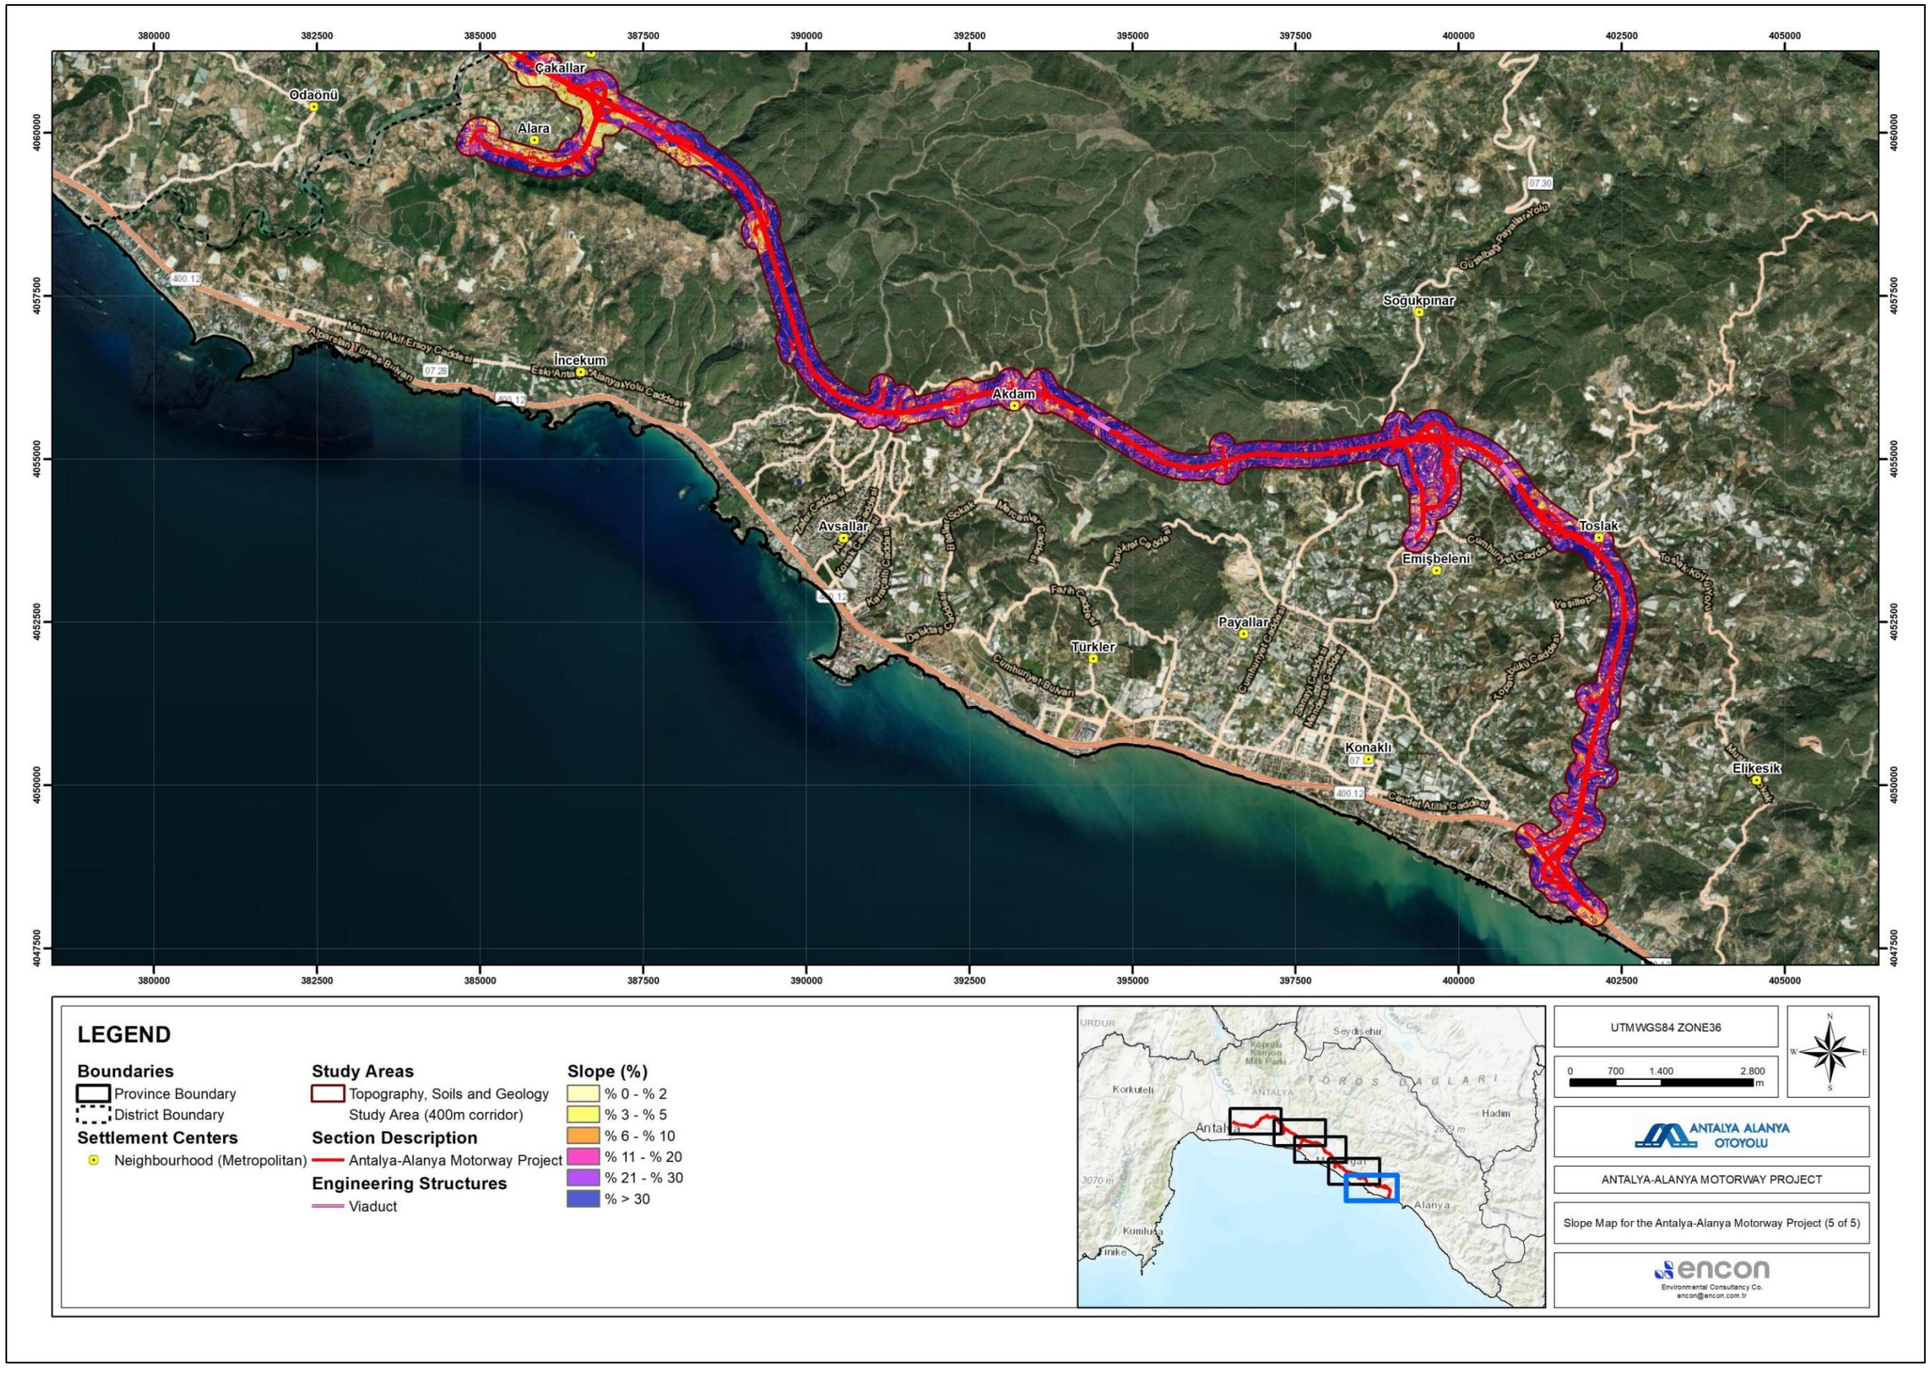

Figure VI.5. Slope Maps of the Project-5

According to the analysis conducted within the study corridor for the Motorway, the following soil groups are identified: non-calcareous brown soils, alluvial soils, colluvial soils, brown forest soils, rendzinas, and red Mediterranean soils. A description of the soil group is provided in Table VI.3.

Table VI.3. Description of Soil Groups

Soil Group	Description
Non-Calcareous Brown Soils	Topsoil is soft or slightly firm. Subsoil is more heavily textured and firmer. Although the lime is washed out, reaction is neutral or alkaline. Natural drainage is good. Natural vegetation cover is forest mixed with bushes and grass or shrubbery.
Brown Forest Soils	These soils are based on high-lime-content parent material. They have weakly developed layers. Their reactions are neutral or alkaline. Lime accumulation is observed in the lower portions of subsoil. They have good drainage.
Alluvial Soil	In these immature soils, layers are either not present or else very weakly developed even if they are present. On the other hand, various mineral layers with different properties are present. These soils which are very important for agriculture are generally under the influence of groundwater and are suitable for growing up all cultivated plants permitted by the climate. The yield could vary between very low and very high.
Colluvial Soils	These groups of soils is accumulated on the foot of step slopes with the effect of gravity, landslide, surface flow or tributaries as a result of transport from short distances and have formed on colluvial material. These young soils rather show the characteristics of the soil materials available in the upper elevations. They contain layers with varying material sizes depending on the level of precipitation and flow rate and the degree of elevation. Those layers are not parallel to each other as they are with the alluvial soils. The ones that are present at the foot of steep slopes and valleys generally include rough and coarse materials. With decreased rate of flow, material diameters reduce. These well drained soils are occasionally subject to flooding. Natural vegetative structure is dependent on the climate. They are productive under irrigation.
Rendzinas	The top layer in these soils, which consist of bedrocks with plenty of lime, is dark-coloured. These contain plenty of limestone, marn and pieces of chalk in them. The amount of lime could be little or plenty. Below this layer is a light-coloured calcareous transition layer. Below the transition layer is calcareous bedrocks. Natural vegetation cover is generally forests, but a mixture of bushes, forest and grass can also be found. Natural drainage of these soils is good.
Red Mediterranean Soils	These soils are formed on calcareous lands within the Mediterranean climate zone, typically developing under maquis vegetation and red pine forests. Lime is leached out of the soil, leading to the accumulation of iron oxide, which gives the soil its characteristic red and similar color tones. Due to this distinctive coloration, they are also referred to as "red Mediterranean soils." These soils are of medium fertility.

Source: Former Ministry of Agricultural and Rural Services. July 2008

The key findings of the soil group analyses conducted for the study corridor (6,856 ha) are provided in Table VI.4, and
Figure VI.6 through
Figure VI.10. A summary of the findings is presented below:

Table VI.4. Soil Groups within the Study Corridor of the Project (GDRS. 1993)

Soil Groups	Area (m^2)	Area (ha)	Percent (%)
Brown Forest Soils	15,883,056.69	1,588.31	23.17
Non-Calcareous Brown Forest Soils	8,103,133.76	810.31	11.82
Red Mediterranean Soils	3,031,804.25	303.18	4.42
Rendzinas	22,813,85.24	2,281.39	33.27
Alluvial Soil	14,241,289.36	1,424.13	20.77
Colluvial Soil	3,770,339.34	377.03	5.50
Settlements	184,874.57	18.49	0.27
River	44,053.60	4.41	0.06
River Flood Plain	428,820.08	42.88	0.63
Coastal Dunes	60,104.88	6.01	0.09
Total	**68,561,326.77**	**6,856.13**	**100.00**

As shown in the table, rendzinas are the dominant soil group along the study corridor (33.3%; 2,281.4 ha), which is followed by brown forest soils (23.2%; 1,588.3), alluvial soils (20.8%; 1,424.13 ha), non-calcareous brown forest soils (11.8%; 810.3 ha), colluvial soils (5.5%; 377.0 ha), and red Mediterranean soils (4.4%; 303.2 ha).

Soil Erosion

Soil erosion is refers to the displacement of the upper layer of soil, leading to degradation of the land. This process can occur naturally due to factors such as weather conditions (winds, rains, ice or extreme heat), or as a result of anthropogenic activities like deforestation, agriculture, and construction. The rate of erosion is increased due to improper agricultural practices such as cultivation on relatively high slope lands, plowing of the fields in the direction of the slope, and excessive grazing on pasturelands or deforestation. The primary agents of soil erosion are water and wind, where the former is more prominent. Water erosion takes place on lands with weak or no vegetative cover where runoff can flow with sufficient energy, transporting loosened soil particles down the slope. Consequently the fertile top layer of the soil is lost from the agricultural lands resulting in reduced agricultural productivity, and water quality of the surface water resources deteriorates as a result of sedimentation and eutrophication (Former Ministry of Agricultural and Rural Services. July 2008).

Evaluation of the erosion level to which soils are exposed is done based on the erosion classification system developed by US Department of Agriculture and adopted by several state authorities including Türkiye. Erosion levels specified in this classification system are listed in Table VI.5. Erosion levels corresponding to the Project area are presented in

Figure VI.11 through

Figure VI.15.

Table VI.5. Erosion Levels according to Technical Procedure on Soil and Land Classification Standards

Erosion Level	Definition
Level 1	Low
Level 2	Moderate
Level 3	Severe
Level 4	Very severe

Source: Former Ministry of Agricultural and Rural Services. July 2008.

Following the erosion level classification, erosion potential of the soils corresponding to the study corridor (6,856 ha total area; settlement, river, river flood plain, and coastal dune areas that cover 1.1% of the study corridor and not categorized under any of the soil groups. and are not taken into consideration in the following figures) have been described based on the land use, and soil database of the former GDRS published for Antalya province in 1993. The results of the analyses done in this scope are provided in Table VI.6.

As presented in the table, approximately 57% (3,933.2 ha) of the study corridor corresponds to soils with severe erosion levels (Level 3). This is followed by no or very low erosion level (Level 1), which accounts for about 25% (1,691.8 ha) of the study corridor. Soils with very severe erosion levels (Level 4) occur in about 2% of the study corridor. Soils with moderate erosion levels (Level 2) along the study corridor account for approximately 15% of the area. In addition, it should be noted that the Project area has experienced a rapid urbanization rate, especially in the last 30 years resulting in significant changes in the land use patterns and an increase in the overall area of artificial surfaces, including urban areas, industrial sites, transport networks, mine extraction sites, etc. Consequently it is likely that the erosion rate has accelerated, and the erosion exposure levels of the soils corresponding to the study corridor have increased.

Additionally, erosion levels of soils of the settlements within the study area are listed in Table VI.6.

Table VI.6. Erosion Potential of the Soils within the Study Corridor of the Project (GDRS. 1993)

Erosion Levels	Risks	Area (m^2)	Area (ha)	Percent (%)
None or very low	-	4,599,930.62	459.99	6.71

Soil Productivity and Quality

Soil productivity represents the capability of soils to supply primary nutrients in sufficient amounts and ratios proper for sustaining the growth of plants. Elements necessary for plant growth include carbon, hydrogen, and oxygen that are supplied from air and water. Additionally, plants require macronutrients such as and nitrogen (N), phosphorus (P), potassium (K), calcium (Ca), magnesium (Mg), and sulphur (S), as well as micronutrients including iron (Fe), manganese (Mn), boron (B), molybdenum (Mo), copper (Cu), zinc (Zn) and chlorine (Cl) which are primarily supplied by soil and/or fertilizers.

The topsoil to be stripped along the Motorway route is expected to extend 25-30 cm below the ground surface. This topsoil layer is rich in humus (soil organic content) and has high microorganism activity, providing favorable conditions for plant growth. The typical composition of topsoil content is provided in Table VI.8 (*KGM. 2013*).

Table VI.8. Typical Composition of Topsoil

Parameter	Value / Concentration
pH	6.0 - 7.5
Lime (%)	4.0 - 9.0
Minimum organic material (%)	2.5 -1 2.0
Salt (%)	0.0 - 0.15
Nitrate-N (NO_3-N) (ppm)	25
Phosphoric acid (ppm)	15
Potassium oxide (ppm)	150

Soil Sampling and Analyses

Most of the Motorway route passes through agricultural lands and forest areas where the historical soil contamination potential is considered to be low. However, there are quarries, and remote settlement areas close to the study area where illegal waste disposal activities could occur. Thus, such areas may include contaminated lands.

Soil contamination is evaluated as a potential risk during the land preparation and construction works, road repair and maintenance activities, and accidents/emergencies during operation phase. This potential risk may arise from accidental spills during transfer, mixing, and storage of hazardous materials or from unexpected incidents.

A soil sampling and laboratory analysis program was conducted as part of the baseline studies for the Project. Initial soil sampling and laboratory analyses were conducted as of September 2024. Sampling locations are listed in Table VI.9 and shown on the map presented in
Figure VI.15 Laboratory result forms are presented in Annex-2.

Table VI.9. List of Soil Sampling Locations (September, 2024)

Station Name	Station Location	Sampling Date	Coordinates of the Station (UTM WGS84-Zone 36)	
			X (North)	Y (East)

T-7	Alanya / Konaklı	24.09.2024	402035	4051679

An additional soil sampling was conducted at 35 locations in May 2025 to enhance the baseline dataset for the ESIA. These supplementary sampling points, shown in
Figure VI.17, were selected to ensure comprehensive coverage of soil quality across all areas associated with the project components. This targeted selection aims to provide a thorough understanding of soil characteristics throughout the entire project footprint. The list of measurement points in May 2025 is presented in Table VI.10.

Measurements were made using EPA 3051 A. EPA 6010 D Method.

The soil measurements conducted in September 2025 provide important data for understanding the environmental conditions in the project area. Most of the measured elements remain at levels significantly below the project standards, indicating that environmental risks are low and soil health is generally at a safe level. In particular, the levels of toxic elements such as Antimony, Mercury, Silver, Tin, and Nickel are well below the limits set by the project, which creates a positive situation in terms of environmental impacts.

However, at certain measurement points, particularly for heavy metals such as Arsenic, Cobalt, Chromium, Zinc, Molybdenum, Thallium, and Vanadium, higher levels have been observed. The main causes of the elevated levels of heavy metals in the soil include natural geological characteristics, industrial activities, agricultural practices, and industrial waste.

It was observed that Arsenic concentrations increased at some measurement points, especially at T-4, T-5 and T-7. These points are located within agricultural areas, and T-4 is situated approximately 400 meters from the nearest settlement. T-7 also lies within the geological unit known as the Payallar Formation, which may naturally contribute to the background arsenic levels. The detected arsenic concentrations are likely influenced by natural geological conditions as well as agricultural activities, such as the historical use of arsenic-based pesticides.

Additionally, factors like air pollution and erosion can contribute to the accumulation of these metals in the soil. Overall, the levels of other elements such as Barium, Benzene, Toluene, Ethylbenzene, Xylene, and Vanadium remain low and do not pose any significant environmental risks.

In addition to the initial measurements, additional soil sampling was carried out at 35 different locations across the project area in May 2025. These new sampling points were selected to cover various project components, including Camp Sites 1, 2, and 3, storage areas, quarries, borrow pits, and other project-related sites. The purpose of these additional measurements was to assess the soil quality in areas that are directly related to the project's activities and ensure that the environmental impact is properly monitored across all relevant components

The following tables present the measurement results in the areas of the relevant project components.

Measurements were made using EPA 3051 A. EPA 6010 D Method

.

Baseline soil samples were collected in May 2025 from eight locations across the quarry areas to assess existing soil quality prior to project activities. The analytical results were evaluated in comparison with the threshold values specified in the Turkish Regulation on Soil Pollution Control and Point Source Contaminated Sites. Overall, the majority of the parameters, including heavy metals such as Nickel, Chromium, Zinc, Lead, Cadmium, and Copper, were found to be significantly below their respective regulatory limits. Additionally, compounds such as Mercury, Silver, Tin, and Total Petroleum Hydrocarbons were either not detected or remained at very low concentrations across all sampling points.

However, Arsenic concentrations were consistently above the regulatory limit of 0.4 mg/kg in all samples, with particularly elevated levels identified at locations T-34, T-35, and T-42. These values are several times higher than the threshold and represent the only notable exceedance within the dataset.

Elevated arsenic concentrations observed at T-34, T-35, and T-42, which are located in forested areas designated for future quarry operations, may be attributed to natural geological conditions, particularly the mineral composition of the underlying bedrock. In undisturbed forest soils, arsenic can accumulate over time due to natural weathering of arsenic-bearing minerals, atmospheric deposition, and limited soil disturbance. Given the absence of significant anthropogenic activities in these areas, the elevated arsenic levels are likely to reflect background geological characteristics rather than external contamination sources.

Despite this, the overall soil quality in the quarry areas, aside from Arsenic, does not indicate any significant contamination concern based on the baseline measurements.

Soil measurements were also carried out in the project campsite and storage areas in these areas. The relevant measurement results are presented in Table VI.13.

Measurements were made using EPA 3051 A. EPA 6010 D Method

Baseline soil samples were collected in May 2025 from seven locations identified for use as camp sites and temporary storage areas. The majority of the analyzed parameters were found to be well below the soil contamination threshold values defined in the Turkish Regulation on Soil Pollution Control. In particular, heavy metals such as Chromium, Nickel, Lead, Cadmium, and Copper showed concentrations significantly lower than their respective limits. Organic contaminants including Total Petroleum Hydrocarbons (TPH) and Total Volatile Organic Compounds (TVOCs) were below detection limits in all samples, and no exceedance was noted for Mercury, Silver, or Tin, except for Tin in T-13, which is still well below the regulatory threshold.

The only notable parameter with consistently elevated values was Arsenic, which exceeded the regulatory limit (0.4 mg/kg) in all samples except T-10. The highest concentration was observed at T-13, followed by other points ranging between 4–6 mg/kg. Additionally, Zinc levels at T-13 were significantly higher than at other locations but still below the threshold value. Overall, while Arsenic concentrations remain above acceptable levels across the area, all other measured parameters indicate that the soil quality in the designated support zones is within acceptable environmental limits based on the baseline data.

T-13 is located in an area where agricultural land borders a forested zone. This transitional location may be influenced by both natural and anthropogenic factors. The presence of agricultural activity suggests the potential for historical use of agrochemicals, particularly arsenic-based agricultural chemicals, which could contribute to elevated arsenic concentrations. At the same time, the proximity to forested land indicates possible natural enrichment through geological processes or atmospheric deposition. Therefore, any detected arsenic levels at this point may result from a combination of natural background levels and diffuse agricultural sources.

Measurements made in areas where storage areas are located are presented in the tables below.

Measurements were made using EPA 3051 A. EPA 6010 D Method

Baseline soil quality measurements were conducted in May 2025 at multiple locations designated for storage areas. The analysis shows that most parameters are well within the acceptable limits defined in the Turkish Regulation on Soil Pollution Control. Heavy metals such as Chromium, Nickel, Copper, Lead, and Zinc were all below their respective threshold values, and organic pollutants such as TPH and VOCs were below detection limits in all samples. Additionally, Mercury, Silver, Tin, and Cadmium were either not detected or detected in trace amounts far below regulatory concern levels.

However, some Arsenic concentrations were found to exceed the regulatory limit at most locations, with the highest levels observed at T-17, T-25, and T-22. Among the soil sampling points designated for future storage areas, the most notable arsenic concentration was observed at T-17. This point is located within a forested area, approximately 200 meters from the nearest settlement. The elevated arsenic levels at this location are likely attributable to natural geological factors, such as the mineral composition of the bedrock and limited anthropogenic disturbance. Given the site's forested setting and distance from intensive human activity, the arsenic concentration may reflect natural background conditions rather than contamination from external sources.

In addition, Zinc levels at T-17 were significantly elevated but still well below the threshold of 23,464 mg/kg. A single Antimony exceedance was recorded at T-17, marginally above the regulatory limit of 31 mg/kg. Despite these isolated high values, the overall soil quality across the storage areas can be considered acceptable for baseline conditions, with most locations showing low levels of contamination.

In addition to the sampling activities conducted in quarry areas, camp sites, temporary storage zones, and designated storage areas, additional soil sampling campaigns were carried out in May 2025 at locations corresponding to the connection road, borrow pit- storage area, and riverbed material extraction sites. These measurements aimed to provide a comprehensive understanding of the baseline soil quality across all key project components and support areas. These measurement results are also presented in Table VI.16.

23	Vanadium	mg/kg	77,1	113,7	46,7

Measurements were made using EPA 3051 A. EPA 6010 D Method

Additional baseline soil samples were collected in May 2025 from three project-related locations: T-8 (connection road), T-9 (borrow pit), and T-29 (river material extraction site). The results show that all parameters, including heavy metals and organic compounds (TPH, VOCs), remain well below the threshold values defined in the Turkish Regulation on Soil Pollution Control. Notably, TPH and VOCs were below detection limits, and Mercury, Silver, Cadmium, and Tin were either undetected or present in negligible concentrations.

As observed in other sampling areas, Arsenic concentrations exceeded the regulatory limit of 0.4 mg/kg in all three locations, with the highest value recorded at T-8. However, no other exceedances were noted. The Nickel concentration at T-9 was the highest among the three, but still well below the regulatory limit of 1564 mg/kg. These results confirm that, aside from Arsenic, the soil quality at the connection road, borrow pit, and riverbed areas is within acceptable limits for baseline environmental conditions.

Although specific asbestos sampling was not conducted during the ESIA baseline studies, the risk of asbestos presence in the project area is considered negligible for the following reasons:

- The project is located between Antalya and Alanya, a region not historically associated with naturally occurring asbestos or former asbestos mining or industrial use.
- The use, production, and import of asbestos have been officially banned in Türkiye since 1984. Given the nature of the project components and the geographic location, no legacy structures or facilities that may contain asbestos have been identified.
- Site inspections and consultations with local authorities and stakeholders did not reveal any evidence or concerns related to potential asbestos-containing materials (ACMs) within the project footprint.

VI.2.3. Geology

The information provided in this subsection is based on a detailed literature review of the Motorway route and its vicinity including reports compiled by relevant authorities and institutions such as on the geology map of the 1/100.000 scale Antalya O-25, Antalya O-26, Alanya O-27 maps prepared by MTA. Detailed investigation reports consisting of geology and geotechnical properties will be prepared separately for the Project Sponsor along the route by an expert geotechnical investigation firm. Upon the completion of mentioned geology report, this subsection will be revised accordingly.

Baseline descriptions are provided under the following subtopics:

- Regional geology
- Stratigraphy
- Project area geology - Lithology
- Geotechnical characteristics
- Structural Geology and Seismicity

VI.2.3.1. Regional Geology

Geological Setting and Tectonic Evolution

Türkiye's geology, in general, is highly complex, and although studied to the extent of a multitude of studies by several researchers, its main features and their relations with each other are yet to be understood clearly. On the largest scale, Türkiye is separated into three main tectonic units, the Pontides, the Anatolides-Taurides, and the Arabian Platform (Ketin, 1966; from Okay, 2008). Formerly surrounded by oceans, these tectonic units are currently separated by suture zones which mark the closing regions of these oceans. A map presenting the main tectonic units of Türkiye is presented in Figure VI.18.

The Anatolides-Taurides present similarities to the continent Gondwana; however, were separated from the main mass of this continent by the southern branch of Neo-Tethys ocean. This ocean, which lies in an approximately E-W direction, at the north of African-Arabian Plates, also closed approximately during Miocene by the continental collision of Anatolian Platform and Arabian Plate. The current eastern section of the Mediterranean is a remnant of this ocean. The ocean closing process is still ongoing and the active subduction zone in the Aegean Region is one of the current indicators of this condition (Okay, 2008). At the end of Middle Miocene, Southern Tethis Ocean was closed due to the continental collision that occurred along Bitlis-Zagros Suture Zone, and also around the same time, towards south of this suture zone, the Red Sea - Aden gulf was formed, pushing the Arabian Plate towards north-northeast. These two large-scale tectonic events caused the formation of North Anatolian Fault Zone (NAFZ) and East Anatolian Fault Zone (EAFZ). On the southwestern boundary of Anatolian-Aegean Plate, Aegean Region tectonic structures were also formed (due to N-S stresses) by north-northeast bound movement of the African Plate. Formation of these fault zones and tectonic structures is considered to be the beginning of Neo-tectonic period in Türkiye and corresponds approximately to Late Miocene – Early Pliocene (Okay, 2008).

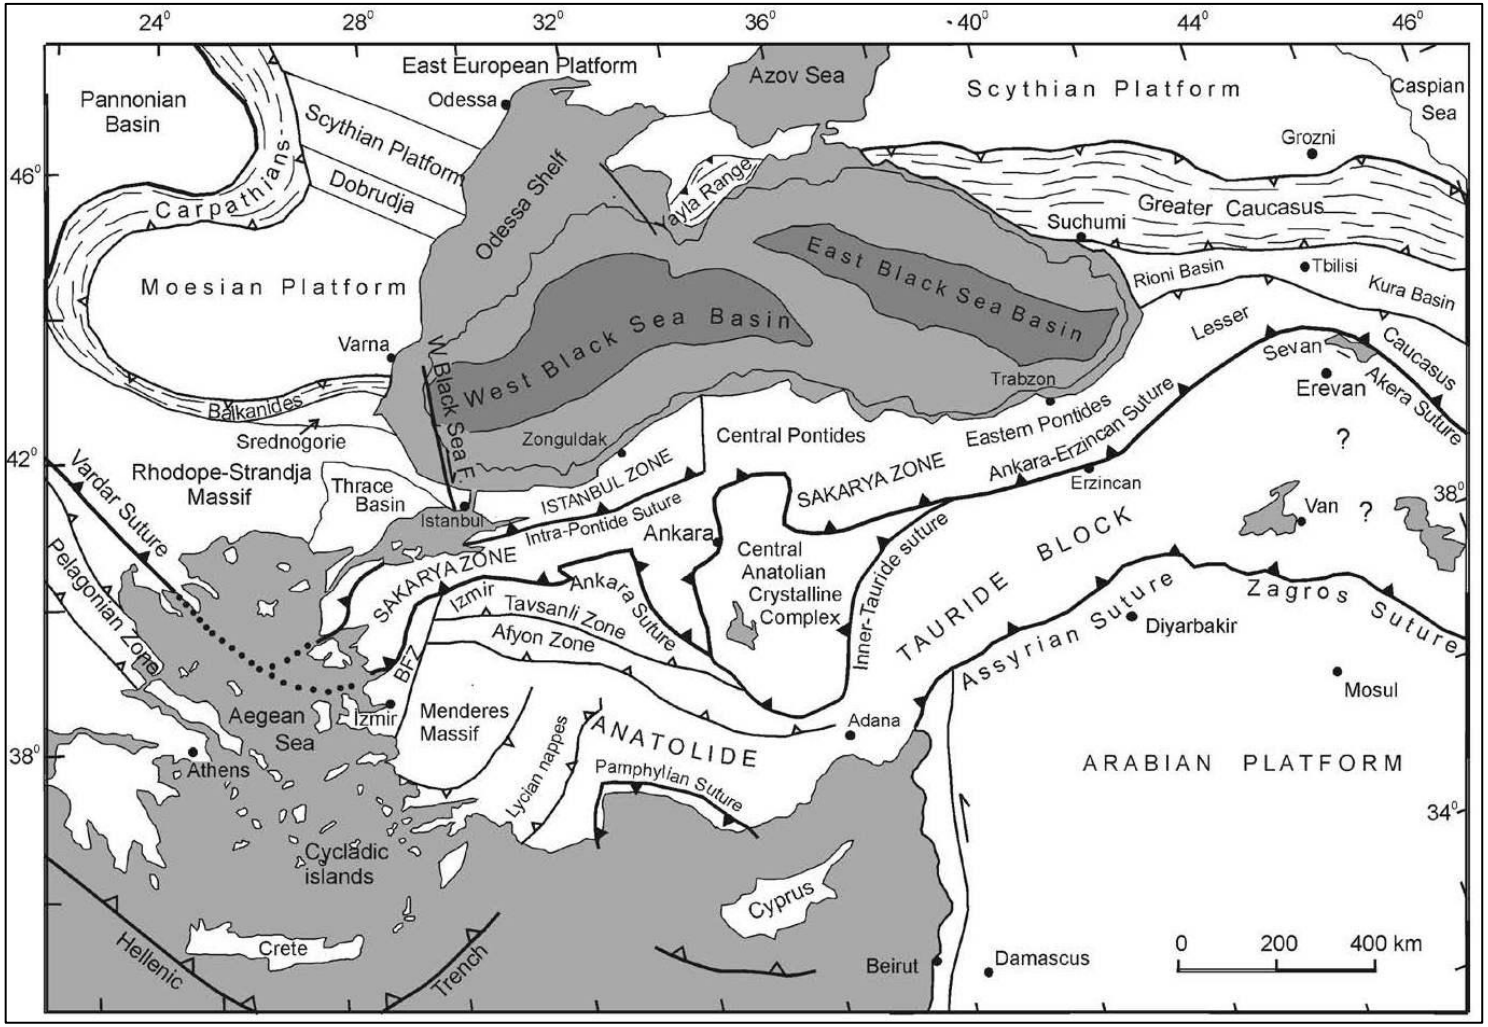

Figure VI.18 Tectonic Map of North-Eastern Mediterranean Region (Okay, 2008).

Representing autochthonous rock units of the Central Taurus, Anamas – Akseki autochthonous together with allochthonous Antalya nappes and Alanya nappe are exposed in region. In the region there are rock units of Anamas – Akseki autochthonous deposited from Late Triassic to Eocene and represented with structural units as Yelekdağ unit, Oğuz unit, Tepedağ unit, Pirnos unit, each of which is thrusted over another. In the region exposed units of the autochthonous are Leylek limestone of Rhaetian built from neritic limestones, late Rhaetian-early Liassic clastics of Üzümdere formation, Liassic Paleodascycladus- and bearing limestones of Alıçbeleni formation, middle-late Liassic dolomites of Hendos dolomite, Jurassic-Cretaceous neritic limestones of Kurucaova formation, Dogger-Malm oolitic-peloidal limestones of Çamkuşağı formation, Malm calciturbidites of Karlığın formation, Dogger-Early Cretaceous Belalan formation, Berriasian pelagic limestones of Susuzkır formation, Campaniyen – Maatsrichtian pelagic limestones of Dumanlı formation, Danian Çamlıdere olistostrome and Late Paleocene-Lutetian İbradi group including carbonates and clastics. The exposed units are Mahmutlar unit, Sugözü unit and Yumrudağ unit of Alanya nappe, the metamorphic counterpart of Antalya nappes as well as the rock units of Çataltepe nappe, Alakırçay nappe and Tahtalıdağ nappe of Antalya nappes, which contain structural units under diverse environmental conditions in the region.

Neoautochthonous deposits covering vast areas in the region are represented with possible Burdigalian-Langhian Kepez travertine and Sevinç conglomerate, Langhian Oymapınar limestone and Çakallar formation, Langhian Geceleme marl and Langhian-Serravalian clastics of Karpuzçay formation. Taşlık formation bearing Messinian clastics, late Messinian-early Pliocene Eskiköy, Yenimahalle and late Pliocene Kurşunlu formation outcrop in restricted areas. Quaternary is represented with Belkıs conglomerate, Moraine, Slope debris/cone of accumulation, Beach deposits, Dune and Alluvium.

Carbonate-dominated lithologies, especially limestones and dolomites of both autochthonous and allochthonous units, have made the region particularly prone to karstification. As a result, karst geomorphology has significantly shaped the regional landscape.

In the region, soluble rocks such as travertine, limestone, dolomite, and transitional types between limestone and dolomite are predominant. These lithologies have played a crucial role in shaping the topography through karstification processes. Karst features dominate the landscape, which has evolved primarily due to the dissolution of carbonate rocks. Tectonism, in particular, and fluvial activity have significantly contributed to the development of karst morphology. The present-day landscape reflects the cumulative effects of karstification, active tectonic movements, and fluvial processes that have been ongoing since earlier geological periods and continue today with varying intensities. In mountainous and plateau areas composed mainly of limestone, typical karstic landforms such as lapiez (karren), dolines, uvalas, poljes, caves, sinkholes, and karstic valleys are widely observed. Among these, poljes form broad, flat-floored depressions within otherwise barren karst terrain, making them important for both settlement and agriculture. The largest examples in the region include Kestel Polje and Elmalı Polje between Antalya and Burdur, as well as Akseki Polje located in the western part of the province.

VI.2.3.2. Stratigraphy

The region is predominantly characterized by the Anamas – Akseki autochthon, which includes rock units that formed between the Cambrian and the Eocene periods. Over these autochthonous units lie the southward-derived Antalya nappes and the Alanya nappe, which were emplaced during the Danian and late Eocene epochs. On top of these autochthonous and allochthonous rock units, there are Middle Miocene and Pliocene-aged rock units, as well as Neotectonic cover formations.

VI.2.3.3. Project Area Geology

The geological units cropping out along the project route and their lithological features are given below from the oldest to the youngest. The geological maps of the Project sections consisting of a total of five (5) sections are presented in Figure VI.19 to
Figure VI.23 respectively.

Lithologies

Paleozoic

Cambrian

Kurtbeleni Formation (Eku)

The Kurtbeleni Formation consists of medium to thickly bedded layers of quartz-schist and intermediate quartzites, displaying a range of colors including white, off-white, reddish-brown, yellowish-brown, and black, with occasional greenish hues. The quartzites are well-bedded, and the quartz grains are notably well-rounded, with sizes ranging between 0.4 and 0.5 mm. The formation exhibits a thickness of approximately 150-300 meters. Based on regional correlation and stratigraphic positioning, the Kurtbeleni Formation is considered to be of Early Cambrian age.

Karagedik Formation (Eka)

The formation begins with thickly layered dolomites in shades of gray, pale yellow, and brown, often featuring dissolution cavities and occasional silica nodules. These dolomites may contain localized barite formations. Overlying these dolomites are medium to thickly layered dolomites in beige, gray, brown, pink, red, and pale yellow colors with marble-like bands. At the top, marble-like dolomites resembling nodular limestones can be found. Within the unit, there are sporadic chert interbeds and cherty dolomites in the upper levels.

The Karagedik Formation is conformably situated above the Kurtbeleni Formation and exhibits a thickness of approximately 250 meters. Though rare, traces of trilobites are observed within this formation. Based on regional correlation and stratigraphic position, it is considered to be of Middle Cambrian age.

Ordovician - Cambrian

Payallar Formation (Eop)

The Payallar Formation primarily consists of chlorite schist and quartz schist in colors including green, gray, greenish-gray, dark green, olive green, yellowish-gray, yellowish-brown, blackish-gray, lead-gray, and bluish tones. These schists are generally medium to coarse-grained and include interbedded quartzites and quartz schists with variable iron and manganese content. In the lower part of the formation, there are red, pink, dirty yellow, and dirty white marbles with fine to medium bedding and occasional laminae of calcite veins, as well as coarsely crystalline marble. Additionally, reddish-brown dolomites with medium to thick bedding, interbedded with baritic dolomites and dolomitic limestones, are present.

The formation is intruded by diabase sills and dykes in some places. These diabase sills and dykes are dark green, dark brown, and black in color and are composed of quartz, albite, epidote, actinolite, and opaque minerals in their finer sections. The formation exhibits a variety of mineralogical

assemblages, including quartz-chlorite-feldspar schist, quartz-feldspar-mica gneiss, muscovite-quartz schist, chlorite-quartz-feldspar schist, quartz-feldspar-mica schist, feldspar-quartz-chlorite phyllite, feldspar-mica-quartz schist, mica-feldspar-quartz schist, feldspar-quartz-mica schist, milonitic schist, chlorite-feldspar-quartz schist, feldspar-sericite-quartz schist, chloritoid-bearing quartz schist, muscovite-feldspar-quartz schist, albite-actinolite-chlorite schist, chlorite-chloritoid quartz schist, feldspar-mica-quartz schist, feldspar-quartz-sericite-chlorite schist, and epidote-actinolite-albite schist.

The Payallar Formation transitions gradationally into the Karagedik Formation and has an approximate thickness of 1000 meters. Based on its stratigraphic position and lithological characteristics, it is considered to be of Late Cambrian to Ordovician age.

Permian

Cebireis Formation (Pce)

The formation begins with a lower section characterized by medium-thick, layered rocks in colors including white, yellow, pink, dirty white, yellowish pink, reddish-brown, black, and beige. This section is interspersed with iron-rich quartzites and quartz schists. The upper portion of the formation features massive, medium-thickly layered rocks in shades of gray, dark gray, black, and blackish-gray. This section includes medium-to-coarse crystalline marble, dolomite, and dolomitic-crystalline limestone. The dark-colored crystalline limestones are occasionally bituminous and may contain silicified fossil traces. The marbles and crystalline limestones are typically medium-to-coarse crystalline, with a sugary texture and/or saccharoidal texture, and exhibit flow features. The dolomites are generally massive, appearing in white-gray, light gray, and sometimes blackish-gray colors. They may be crumbly in places and often contain numerous small voids. The formation has an approximate thickness of 550 meters.

Mesozoic

Triassic

Anisian-Norian

Alakırçay Group (Tra)

The Alakırçay Group is composed of Late Anisian to Norian-aged fossiliferous sandstones, shales, pillow lavas, spilite-altered basalts, radiolarites, cherts, and limestones. These rock types, which transition into one another both laterally and vertically, display a chaotic appearance due to their highly fractured, folded, and complex nature.

Karadere Formation (Trak)

The unit comprises basalt with alkaline characteristics, including pillow lava formations in dark brown, dark green, greenish-black, and reddish hues, as well as spilit and basaltic compositions. It also includes intercalations of layered chert, radiolarian chert, micrite, shale, and occasional agglomerates and tuffs. The formation is intersected by local diabase dikes, with basaltic lavas being the predominant rock type. The unit exhibits lateral and vertical interactions with other formations of the Alakırçay Group. Its thickness ranges from 0 to 700 meters.

Stratigraphically, the formation is considered to be of Ladinian-Norian age. The Karadere Formation developed as a result of rifting associated with the fragmentation of the platform towards the end of the Anisian period.

Cretaceous

Sugözü Formation (Ksg)

This formation encompasses metamorphic rocks that have undergone metamorphism under high-pressure and low-temperature conditions. It is characterized by the presence of dolomite and marble blocks, which are commonly found in large-scale tectonic slices. The dominant rock type in the formation consists of garnet-bearing mica schists with fine to medium to coarsely foliated textures, displaying colors such as green, dirty yellow, gray, greenish-gray, light brown, bluish-gray, leaden, and reddish-brown. In the coarsely foliated sections, garnet, albite, and quartz are particularly prominent. The formation exhibits a highly folded, fractured, deformed, and chaotic structure. The boundary relationships of the unit are tectonic in nature. The formation has a thickness ranging from 500 to 750 meters, but this thickness diminishes laterally.

The metamorphic age of this unit, which includes tectonic slices and rock types of various ages, is assigned to the Late Cretaceous period.

Tekedağı Formation (JKt)

The unit consists of medium-thickness, locally massive limestone, recrystallized limestone, and dolomitic limestone in colors ranging from beige, cream, gray, to dirty white. Dolomitization is commonly observed within the unit. The limestones are present as small fragments. This unit is several tens of meters thick in the region.

Kırkdirek Formation (Kkm)

The serpentinite matrix encompasses blocks of varying sizes including limestone, plant-rich sandstone, shale, layered chert, radiolarite, basic volcanic rocks, and neritic limestone from the Jura-Cretaceous period, gabbro, diabase, and amphibolite. This formation is present as tectonic slices of different sizes within the Antalya nappes, with thickness varying between 0 and 600 meters. It developed during the late Senonian period, influenced by the emplacement of the ophiolite nappe over the continental crust.

Senozoic

Paleogene

Eocene

Kulalar Formation (Teku)

The formation begins with conglomerates derived from the Antalya nappes, characterized by rounded, sub-rounded, and angular clasts with intermediate to poor sorting. Overlying these conglomerates are sandstone, siltstone, mudstone, sandy-clayey limestone, calcarenite, micrite, and conglomerates with gray, green, greenish-gray, dirty yellow, and white colors, exhibiting irregular intercalations with fine to medium and locally coarse layers. Above these, there are additional conglomerates, also derived from the Antalya nappes, featuring angular clasts and intermediate to poor sorting, with a thickness of approximately 7 meters.

The total thickness of the formation is about 280 meters. This unit was deposited in a slope-basin environment influenced by turbidity currents.

Çakallar Formation (Tmça)

The unit typically consists of medium-thick, finely laminated breccias of limestone origin in colors such as beige, cream, gray, and dirty yellow. Within this formation, intermittent layers of brecciated limestone, calcareous shale, and marl are observed. It exhibits a thickness of approximately 330 meters. The unit is laterally interfingered with the Oymapinar Limestone and is considered Langhian in age based on its stratigraphic position. It was deposited in a shallow carbonate shelf environment.

Neogene

Miocene

Sevinç Conglomerate (Tmse)

The unit is generally characterized by stratified and/or thickly layered conglomerates, which are represented in reddish, brown, and gray colors. The pebbles within the unit vary in type and are typically rounded or well-rounded. In some areas, the pebbles exhibit moderate to good sorting, while in others, they show moderate to poor sorting. Locally, the conglomerates may resemble limestone, with pebble sizes reaching up to 60-70 cm. The Sevinç conglomerate occasionally includes layers of sandstone and sometimes mudstone. These sandstone and mudstone layers are brownish in color, with their thickness tapering laterally to form lens-like appearances. The layers exhibit cross-stratification and trough cross-stratification. Within the unit, plant fragments are present in places.

Oymapınar Limestone (Tmo)

The formation, exhibiting transgressive characteristics, typically begins with thin to medium-bedded, beige, cream, dirty yellow, and gray reefal limestones and conglomeratic limestones. In some areas, the base includes conglomerates, while in others; it starts with sandstones, mudstones, and conglomeratic limestones in intermediate levels. The upper part of the formation is characterized by dominant rock types, including locally medium-bedded, beige, cream, dirty yellow, dirty white, and light gray reefal limestones with occasional dissolution voids. The Antalya Nappes, which are unconformably overlying the Alanya Nappe, are locally unconformable over the Oymapınar Limestone and the Sevinç Conglomerate. The unit averages about 100 meters in thickness but shows lateral variability. It was deposited in a shallow carbonate shelf environment.

Karpuzçay Formation (Tmkp)

The Karpuzçay Formation is characterized by its finely, moderately, and coarsely layered sediments. It comprises sandstones, siltstones, and shales in a range of colors including gray, greenish-gray, light brown, dirty yellow, green, beige, and cream. Notably, the lower sections of the formation contain calcite turbidites and clayey-silty limestone layers. Additionally, the formation includes conglomerate layers in certain areas. Sparse fine tuff layers are also present within the formation. The thickness of the unit varies approximately between 20 and 450 meters. It was deposited under the influence of turbidity currents, initially in a shelf environment, and subsequently in slope and basin settings.

Geceleme Marl (Tmg)

The formation is composed of fine clayey-silty limestones, calcite turbidite levels, and thin to medium-thick beds of claystones and marls in shades of greenish-gray, gray, light gray, green, cream, and dark gray. It also includes occasional thin sandstone interbeds. The thickness of the unit ranges from 20 to 450 meters. This unit was deposited in a deep shelf-slope environment.

Aksu Formation (Tma)

The Tortonian aged formation consists of thick conglomerates. The unit consists of massive, thick, sometimes medium-bedded, medium to well-graded, rounded, semi-rounded, sometimes angular pebbly and sometimes blocky conglomerates. Sometimes sandstone, claystone, siltstone, marl and marl can be interbedded within the unit. It shows a maximum thickness of 400 meters in the region. The unit was deposited in shelf-slope environment.

Pliocene

Eskiköy Formation (ple)

The unit consists of massive or very thickly bedded terrestrial conglomerates at the base, and marine conglomerates, sandstones, and siltstones with thick bedding at the top. The thickness varies between 0 and 400 meters. This formation, dated to the Late Messinian to Early Pliocene, was initially deposited in a terrestrial environment and later in a coastal setting.

Quaternary

Pleistocene

Belkıs Conglomerate (Qb)

The unit consists of polygenic conglomerates. These conglomerates are typically characterized by rounded to well-rounded gravel, supported by the clasts, and exhibit indistinct and cross-bedded structures, with a matrix of sand and mud. The conglomerates may also include interbedded mud and ancient soil horizons. The thickness of these deposits ranges from 0 to 20 meters. The Belkıs Conglomerate, which is considered to be of Pleistocene age, has an alluvial origin and is found in terrace formations.

Alluvium (Qal)

In riverbeds and alluvial plains, sedimentary deposits such as sand, gravel, cobbles, and mud accumulate. When rivers reach the sea, these materials are deposited as deltaic sediments.
The geological map of the project area is presented from Figure VI.19 to Figure VI.23.

VI.2.3.4. Geotechnical Characteristics

Within the scope of the project, a Geological–Geotechnical Survey Report was prepared by Mega Mühendislik Müşavirlik A.Ş. in 2024. This report formed the basis for the geological mapping, exploratory boreholes, trial pits, field testing, sampling, and laboratory analyses conducted along the designated route.

According to the findings and planning framework outlined in the Geological–Geotechnical Survey Report, a total of 417 boreholes were proposed—32 on the Serik Junction and Connection Roads, 19 on the Antalya State Highway, and 366 along the main project corridor. However, due to constraints such as permitting challenges, expropriation procedures, and limitations in site accessibility, the report notes that not all boreholes could be completed during the preliminary phase. The execution of the remaining boreholes has been scheduled for the construction stage, in line with the report's recommendations.

Similarly, the test pit program included 23 test pits on the Serik Junction and Connection Roads, 6 on the Antalya State Highway, 4 superstructure pits, and 55 along the main route. Field investigations for test pits are currently ongoing.

The drilling activities were carried out to determine the engineering properties of the soil and rock units. The drilling was carried out by drilling self-contained wells with rotary water system and wire-line type drilling equipment was used. Standard penetration tests (SPTs) were performed every 1.5 meters along the soil profile and soil samples were taken during these tests and preserved in double-layer nylon bags. Undisturbed samples of fine-grained soils, especially those with high clay and silt content, were obtained with a Shelby tube (UD) and paraffinized immediately to preserve the natural water content of the samples. In order to determine the groundwater level, the wells were emptied, waited for 24 hours and then measured. The samples were analyzed in the laboratory for soil index properties (natural water content, grain distribution, Atterberg limits), strength parameters (cohesion, internal friction angle) and deformation properties (swelling, compaction parameters). Core drilling method was applied in the bedrock units, core samples were numbered and stored in core boxes and logged and archived. All works were carried out in accordance with the "Technical Specifications for Soil Investigations" of the General Directorate of Highways, TSE and international standards.

(*) Due to reasons such as permits, expropriation, land conditions, etc., the point could not be reached and drilling will be carried out during the construction phase. (Geological–Geotechnical Survey Report,2024)

According to the Geological - Geotechnical Investigation Report, there is no potential to encounter trapped water during excavations along the project route as there will be no passage through the porous - hollow karstic Antalya travertines, which have the potential to transport water.

Terrain models have been created based on topographic structure, geological and geomorphological features and project criteria so as not to require stability analysis for slits not exceeding 15 meters in height and embankments not exceeding 8 meters in height. In addition, in cases where the depth of the fill does not exceed 5 meters, in accordance with the General Directorate of Highways' Internal Circular dated March 09, 2009 and numbered 2007/73, the fill slope ratios are determined as follows:

Depth of Fill (H)	Slope Ratio (h/v)
0.00 m < H ≤ 1.50 m	4 / 1
1.50 m < H ≤ 3.00 m	3 / 1
3.00 m < H ≤ 5.00 m	2 / 1

For fills of 8 meters and above, the following safety coefficients must be provided in the slope stability analyses:

- Short term: G.S. ≥ 1.30
- Long term (static): G.S. ≥ 1.50
- Long term (earthquake): G.S. ≥ 1.10

Stability analyses to be performed in embankment areas, bearing capacity and settlement behavior of embankments and culverts will be evaluated in accordance with national and international standards and these analyses will be presented in the Route Geotechnical Report to be prepared by the company preparing the Geological - Geotechnical Investigation Report.

Acording to the Geological–Geotechnical Survey Report, a total of five tunnels are located along the project route. Detailed geological and geotechnical evaluations for these tunnels, including the entrance and exit portal areas, are planned to be addressed in the Portal and Tunnel Geological–Geotechnical Investigation Reports and Tunnel Calculation Reports, which will be prepared at a later stage by the contractor. The excavation classifications and slope angles presented in the current report pertain solely to the general alignment and do not include the tunnel portals. Slope design and geotechnical assessments for the portal zones will be carried out separately by the contractor in the relevant specialized reports.

VI.2.3.5. Structural Geology and Seismicity

Türkiye is located in one of the most actively deforming regions in the world. The tectonic in and around Türkiye depends on relative motions between the African, the Aegean, the Arabian, the Anatolian, the Black Sea, and the Eurasian plates. Neotectonics in Türkiye is mainly governed by the following three tectonic elements (*Kasapoğlu and Toksöz, 1983; Bozkurt, 2001; from Bayrak et al. 2011*):

- A convergent plate boundary where the African Plate to the south is subducting beneath the Anatolian Plate to the north
- The dextral North Anatolian Fault Zone
- The sinistral East Anatolian Fault Zone

Western Türkiye is located in one of the most seismically active regions in the world, owing to the fact that this region is located close to three large plate boundaries that are in constant movement (Taymaz et al., 1991). The kinematics of the regional deformation of the Aegean-Anatolian region is controlled by three critical factors (
Figure VI.24). These are the westward motion of the Anatolian microplate relative to the Eurasian plate, the collision between northwest Greece-Albania and the Apulia-Adriatic platform, and the presence of the Hellenic subduction zone to the south of the Aegean province (Taymaz et al., 1991).

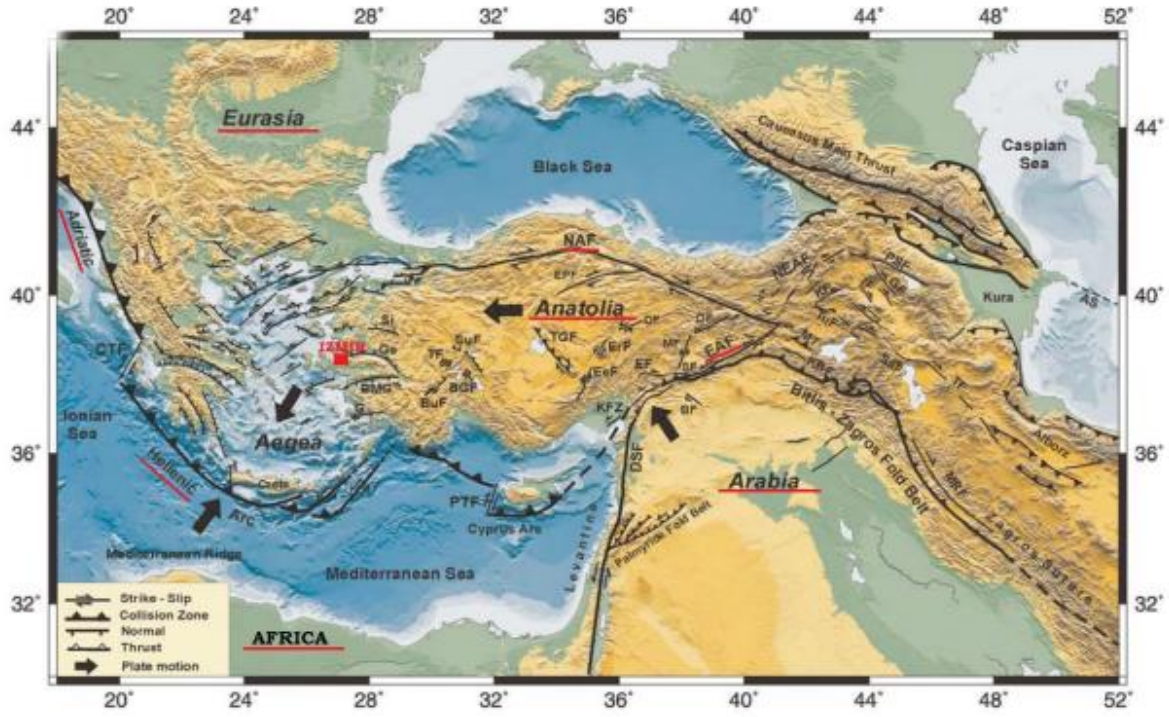

Figure VI.24 The eastern Mediterranean region, including faults and relative motions between plates/microplates

The westward motion of the Anatolian microplate is related to a collision in eastern parts of Türkiye and the Caucasus between the Arabian plate in the southeast and the Eurasian plate in the northwest. This motion is accommodated along two large well known strike-slip faults, namely “North Anatolian Fault Zone (NAFZ)” and “East Anatolian Fault Zone (EAFZ)”, which has right lateral and left lateral displacement, respectively (Taymaz et al., 1991). The collision between the Arabian and the Eurasian plate causes a crustal thickening, and the effect of the crustal thickening provides a buoyancy force that drives the Anatolian plate westwards, a process which has started about 12Myr ago back in the mid-Miocene (Taymaz et al., 1991).

The collision of the Arabian plate with the Eurasian plate is still active. This is causing the accumulation of high topography in eastern Türkiye and the Caucasus, driving the westward motion of the Anatolian and the Aegean plate. Continental materials are still being pushed over the oceanic crust of the eastern Mediterranean, forming the Hellenic subduction zone and the subducting slab beneath the Hellenic trench, thus maintain the present extension seen in the Aegean area (Taymaz et al., 1991). This extension is oriented NNE-SSW direction.

The Antalya nappes are allochthonous masses that formed during the Late Campanian – Maastrichtian as a result of oceanic crust being thrust over continental crust. During the Danian period,

these nappes were situated to the east and northeast of the Beydağları autochthon and to the south of the Anamas – Akseki autochthon. The potential metamorphic counterpart of the Antalya nappes, the Alanya nappe, underwent metamorphism during the Late Campanian – Maastrichtian. During the Maastrichtian, the Alanya nappe tectonically overthrust the Antalya nappes. Additionally, during the Danian, the Alanya nappe, along with the Antalya nappes, was positioned along the southern margin of the Anamas – Akseki autochthon.

In the Eocene, the northward migration of the Beyşehir – Hoyran – Hadim nappes led to their emplacement over the Anamas – Akseki autochthon. This emplacement, driven by north-south compressional forces, resulted in the Antalya nappes and the Alanya nappe being positioned along the southern margin of the Anamas – Akseki autochthon. However, the north-derived Beyşehir – Hoyran – Hadim nappes locally overstepped the Anamas – Akseki autochthon, overriding the southern Antalya nappes and the Alanya nappe.

During the Middle Miocene transgression, the region was affected by north-south compressional forces, leading to the folding of Miocene sediments towards the end of the Miocene. Subsequently, during the Pliocene and Quaternary periods, the region experienced faulting events.

The locations of the epicenters of historical earthquakes that occurred around the route between 1900-2024 period, with a magnitude greater than 4 are summarized in Table VI.20, and their locations are shown in
Figure VI.25.

According to the earthquake hazard map of Türkiye prepared by the Disaster and Emergency Management Presidency, the ground acceleration velocity (PGA 475) of the project varies between 0.216g and 0.237g. The ground velocity (PGV 475) of the Project varies between 9.1 - 10.4 cm/sec. The earthquake hazard map of Türkiye is presented in

Figure VI.26, and the active fault map of the Motorway route and its general region is given in Figure VI.27.

VI.3. Potential Impacts

Direct impacts on topography, soil, and geotechnical risks will be a concern mainly during the land preparation and construction phase of the Project since construction works involves significant interaction with the environmental components. During the operation phase, while direct and extensive physical interaction with the environmental components, including soil, will be less, there is still potential risk of soil contamination due to accidents and geotechnical and seismic hazards. This potential risk is one of the primary concerns for the operation phase. Assessment of the impacts for the land preparation and construction, and operation phases in consideration of the baseline conditions is provided in the following subsections.

VI.3.1. Land Preparation and Construction Phase

The Project will involve substantial earth-moving activities and civil works in the land preparation and construction phase. These activities, including topsoil stripping activities, cut and fill operations, and other construction works, may impact existing soil conditions if not properly managed. Additionally, geotechnical risks along the Motorway route have to be accurately identified to ensure the safety and stability of the large structures to be constructed. Mitigation measures will be taken in order to minimize the risk of erosion, geotechnical risks, and risk of soil contamination.

VI.3.1.1. Impacts on Topographical Conditions

Topographical conditions are crucial in the design and construction of a motorway, influencing aspects such as cut and fill operations, road alignment (including curves), and the design of engineering structures (e.g., viaducts, excavations, embankments). Measures to address geotechnical risks, such as landslides, erosion, and rockfalls are directly related to topography. In addition, operation and maintenance costs are also affected by the topographical conditions of the selected route.

Excavation (cut) and embankment (filling) operations required for the construction works will create elevation differences along the selected motorway route, leading to noticeable and permanent changes in the topography of the Project area. Moreover, material extraction activities at quarry sites will contribute to these local topographical alterations. Within this respect, the excavation and fill volumes with 3 km intervals are shown in Table VI.21.

Table VI.21 Excavation and Fill Volumes for the Motorway

Start	Finish	Cut (m^3)	Fill (m^3)	Balance (Cut – Fill) (m^3)	Topsoil Cut to Depot

VI.3.1.2. Impacts on Soil Environment

Potential impacts of the land preparation and construction activities on the soil environment may include soil disturbance (e.g., loss of fertile top layer, mixing of soil layers and types, soil compaction, etc.) due to topsoil stripping, cut and fill operations, construction of road structures and extraction of construction materials at the quarry sites; soil erosion and soil contamination due to unexpected leakages or spills. Further evaluation of the potential impacts is provided in the following paragraphs.

Soil Disturbance due to Earthworks, Construction and Materials Extraction

Soil disturbance will occur across all sites where topsoil stripping, excavation, construction activities, including operation of heavy machinery operations, and materials extraction activities take place.

<u>Topsoil Stripping</u>

Prior to the commencement of construction activities, topsoil corresponding to the footprint of the Project components (road body, excavation and embankment sites, engineering structures, quarries etc.) will stripped to a sufficient depth, which is anticipated to be about 20-30 cm depending on local soil conditions.

The land-use characteristics along the expropriation area were determined based on the CORINE 2018 database. Since construction campsites have already been established, these sites have not been included in the assessment. Also, the quarries are not included in the calculations.

Without proper management, topsoil along the Motorway route could be lost due to erosion, mixing with coarse soils or contaminated soils during the land preparation and construction phase. Thus, topsoil management measures have to be applied throughout the Project, as described in the following subsections.

Cut and Fill Operations

Depending on the topographical conditions, cut and fill works will be carried out along the Motorway route and at the foundations/portals of the engineering structures. Planned excavation works in this scope are summarized below:

- Excavations along the Motorway route to develop road body;
- Excavations to remove weak soils (soils with poor static properties) beneath the road base;
- Excavations at material borrow pits to provide fill material;
- Excavations to prepare foundations for engineering and drainage structures.

Excavation and fill volumes have been given previous chapters. Depending on the quality and quantity of the excavated materials, they will be used as fill materials when suitable.

The Project is anticipated to result in the removal of vegetative cover along its 84 km main route, 33.8 km connection routes, and also at quarries, borrow pits, and excavated material storage sites. The earthworks and construction activities will be conducted within the expropriation corridor, which will have a width of 55 to 450 m, but the direct physical interaction with soils will occur at the footprint of the Project components (i.e., road body, portals, and foundations of engineering structures, etc.). The potential impacts of soil erosion on the receptors/resources will vary depending on existing exposure levels. The Table VI.6 presents the sensitivity of the Project area in terms of soil erosion impact. Within the study area, approximately 57% (3,933.2 ha) of the study corridor corresponds to soils with severe erosion levels (Level 3). This is followed by none or very low erosion level (Level 1), which accounts for about 25% (1,691.8 ha) of the study corridor. Soils with very severe erosion levels (Level 4) occur in about 2% of the study corridor. Soils with moderate erosion levels (Level 2) along the study corridor account for approximately 15% of the area. The amount of soils that will be mobilized will depend on the construction techniques.

Soil Contamination

Soil contamination may occur in several ways during the land preparation and construction phase (e.g., construction and materials extraction works) of the Project as described by Joint Assistance to Support Projects in European Regions (*JASPERS, 2010*) in the Sectoral EIA Guideline for motorway and Road Construction Projects. This may contribute to any historical contamination present at the

works sites or deposition of pollutant substances (SO_2, NO_x, and heavy metals) that occur by means of rain and snowfall. Potential sources of soil contamination for the Project, for which mitigation measures will be developed and taken, are listed below (*JASPERS, 2010*):

- Spreading on and infiltration of pollutant substances into the soil as a result of uncontrolled or accidental discharges, spills or leaks of hydro-carbons (oils, lubricants, fuels, dyes, solvents) along the Motorway construction corridor (i.e., from construction machinery) and at work sites including asphalt plants, concrete plants, etc. during transfer, mixing, storage or use of substances;
- Deposition of dust, possibly contaminated with other air pollutants, resulting from earthworks, loading, and unloading of raw materials, construction traffic, asphalt plants, concrete plants, etc.;
- Spillage/leakage from sewerage network and the infiltration of water loaded with binders, cement mixtures, and suspensions from concrete plants platforms or other construction locations;
- Infiltration of leachate from uncontrolled deposits of wastes and construction materials.

Due to the unpredictable nature of contamination events, it is not possible to accurately estimate the amount and frequency of accidental spills or leakage of hazardous substances. However, such incidents are expected to occur only occasionally. Immediate response measures will be implemented to ensure that any spill or leakage is contained before reaching significant levels. Additionally, the Project does not involve the use of substantial quantities of hazardous materials, which further limits the potential magnitude of any single spill or leakage event.

Contaminated Land

Land is considered contaminated when it contains concentrations of hazardous substances or oil above background or naturally occurring levels due to historical activities. Contaminated land mapping poses a risk to the health of the construction workforce and the ecology. It may also impose liabilities (e.g., remediation costs, damage to the business reputation and/or business-community relations) on the owner planning activities at such sites (IFC, April 2007).

Some of the Project components (campsites, storage areas etc.) were or will be established in formerly degraded areas and/or close proximity to settlements. As a result, these locations may contain contaminated land. Furthermore, in the land preparation and construction phase, soil remediation efforts and/or the removal of existing layers of soils, particularly in disturbed areas, are being considered to ensure geotechnical stability during construction. Consequently, addressing the treatment of contaminated soils may be an important issue to avoid interaction of contaminated and uncontaminated land through transport or release of contaminants.

VI.3.1.3. Geological and Geotechnical Risks

The geotechnical and geological investigations of the baseline are conducted to ensure the requirements for stability of the road during the construction and operation phase and that the route selection process reflects these characteristics. Geotechnical assessments are also required to assess the stability, settlement, and integrity of the designed structures. Thus, the significance of instability and erosion potential of soils is first and foremost defined by the various applicable minimum

design factors and the corresponding geological and geotechnical properties required to achieve the design standards.

Stability analyses to be performed in embankment areas, bearing capacity and settlement behavior of embankments and culverts will be evaluated in accordance with national and international standards and these analyses will be presented in the Route Geotechnical Report to be prepared by the company preparing the Geological - Geotechnical Investigation Report.

Exploration pits and drilling works are still ongoing within the scope of the Project and according to the studies conducted, there is no karst geological hazard.

Stability and Landslide Risks

Drilling operations are currently ongoing under the Geological and Geotechnical Survey Report for the existing route. The assessment of potential landslides along the Project route was made in line with the 1/500.000 scale MTA Landslide Risk Map (**Error! Reference source not found.**). According to Figure VI.28, there are no ancient or active landslides in the immediate vicinity of the Project.

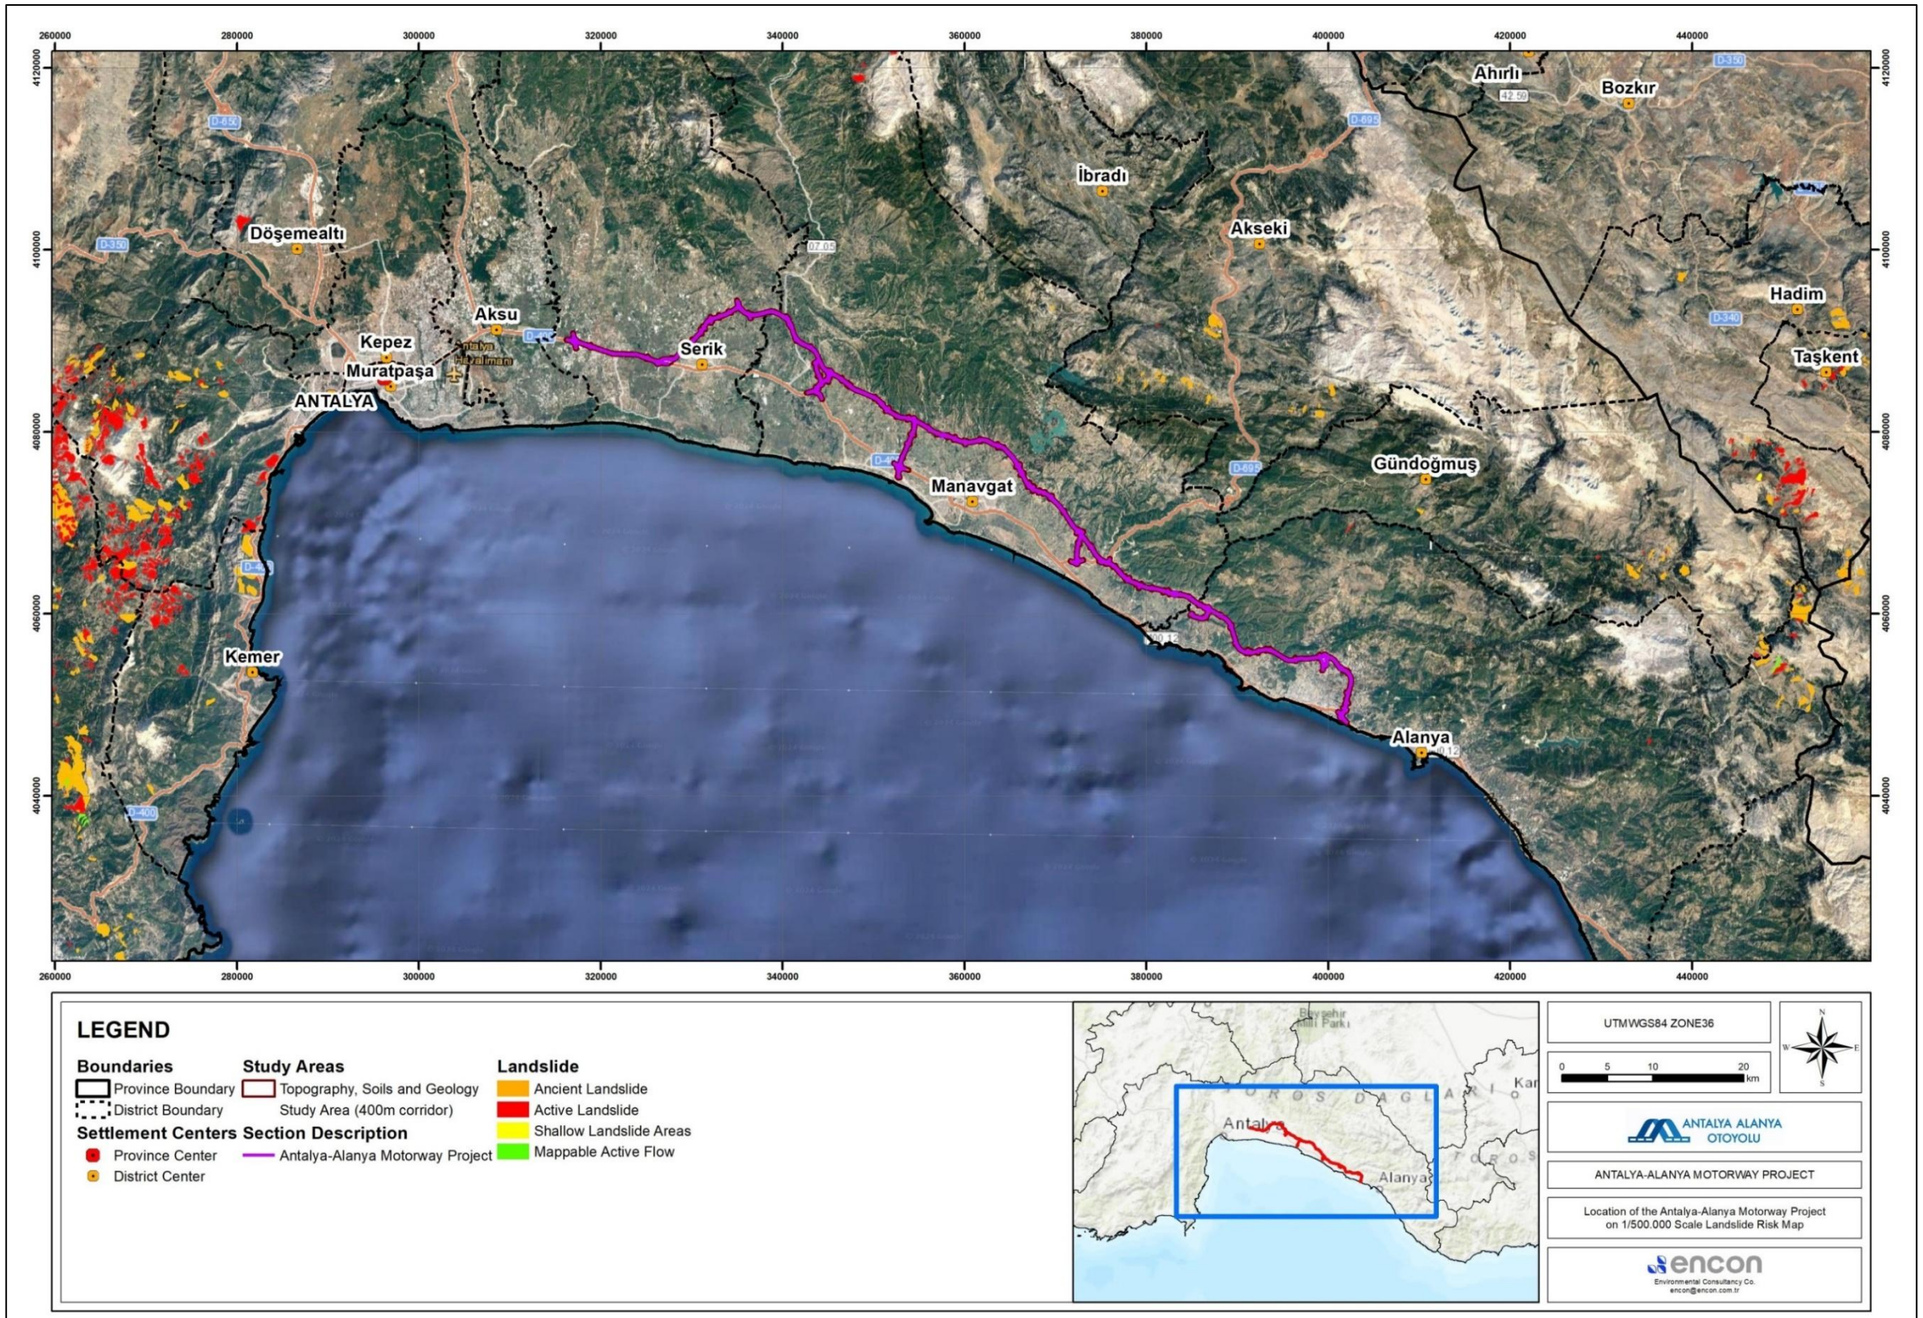

Figure VI.28 Location of the Project on 1/500.000 Scale Landslide Risk Map

Seismic Risk

The Earthquake Hazard Map of Türkiye, prepared by the Disaster & Emergency Management Authority Presidential of Earthquake Department, has been prepared with very detailed data, considering the most recent earthquake source parameters, earthquake catalogs, and new generation mathematical models. In the map, the highest ground acceleration values are shown instead of earthquake zones, and the concept of "earthquake zone" is eliminated. It assumes that a normal construction, which has 50 years of economic life, may not be exposed larger than these expected maximum acceleration values with 90% probability. For the important structures or buildings that have longer economic life, maximum acceleration values should be calculated. The horizontal equivalent earthquake coefficient to be used in the stability analyses was calculated according to the Principles for the Design of Road and Railway Tunnels and Other Ground Structures Under Earthquake Effects (2020). According to the earthquake hazard map of Türkiye prepared by the Disaster and Emergency Management Presidency, the ground acceleration velocity (PGA 475) of the project varies between 0.216g and 0.237g. The ground velocity (PGV 475) of the Project varies between 9.1 - 10.4 cm/sec.

The Motorway is required to be designed and built to stringent Turkish and international engineering standards that will minimize the potential damage in the event of an earthquake. In the seismic calculations, the Standard Specifications used for the seismic design of the highway bridges have been taken as a basis. Where required, Project-specific revisions have been or would be done with the approval of KGM to adapt these specifications to the Project adequately.

Local soil classes for the critical section along the route are mostly ZC-ZD. Table and earthquake parameters to be used in stability analyses are as follows.

Table VI.22 Local Soil Classes (Principles for the Design of Highway and Railway Bridges and Viaducts Under Earthquake Effects, 2020)

LOCAL SITE CLASSIFICATION	Soil/Rock Type	Average Properties in Upper 30 m		
		$(V_s)_{30}$	$(N_{60})_{30}$	$(c_u)_{30}$
		[m/s]	[blows/30cm]	[kPa]
ZA	Intact, hard rock	> 1500	–	–
ZB	Slightly weathered, moderately strong rock	760 – 1500	–	–
ZC	Very dense sands, gravels, and stiff clays, or weathered and heavily fractured weak rock	360 – 760	> 50	> 250
ZD	Medium dense to dense sands and gravels, or very stiff clays	180 – 360	15 – 50	70 – 250
ZE	Loose sands and gravels, or soft to stiff clays; includes profiles with soft clays (cu < 25 kPa) thicker than 3 m, meeting PI > 20 and w > 40% conditions	< 180	< 15	< 70
ZF	Soils requiring site-specific investigation and evaluation:			
	1) Soils at risk of subsidence and potential collapse under earthquake impact (liquefiable soils, highly vulnerable clays, collapsible weak cement soils, etc.),			
	2) Peat and/or clays with high organic content with a total thickness of more than 3 meters,			
	3) High plasticity (PI >50) clays with a total thickness of more than 8 meters,			
	4) Very thick (> 35 m) soft or medium stiff clays.

ZF	*Site Specific Soil Behavior Analysis will be Conducted*					

Flood Risk

Within the scope of the project, a Hydraulic–Hydrological Study Report was prepared by Mega Mühendislik Müşavirlik A.Ş. in 2024.

According to the findings and planning framework outlined in the Hydraulic–Hydrological Study Report, the catchment area was delineated in the hydrologic studies, and floods with 10, 100, and 500 years were extracted with rational, synthetic unit hydrograph for 305 culverts. More information on floods is given in section VIII.2.2.2. Running Water Bodies.

VI.3.2. Operation Phase

In the operation phase, the activities will not involve any additional physical interaction; thus no additional significant direct impact on topography, soils, and geological conditions is anticipated under normal operating conditions.

However, risks of soil contamination may arise from improper handling of the hazardous materials used in the road repair and maintenance activities, as well as leaks/spills of fuels, chemicals, etc., during accidents or emergencies. The potential impacts from these risks would be similar to the impacts described for the construction phase, and a similar mitigation strategy will be employed to address these issues. Additionally, seismic risks will be a concern throughout the entire operational life of the Motorway; thus, further evaluation on these risks and mitigation approaches is provided below.

Impacts on Soil Environment

Impacts on the soil environment during operation phase are anticipated to be limited. However, risks of soil contamination may arise from improper handling of the hazardous materials used in the road repair and maintenance activities, as well as leaks/spills of fuels, chemicals, etc., during accidents or emergencies. JASPERS (2010) list the potential impacts for operation phase in its Sectoral EIA Guidelines for motorway and Road Construction Projects as follows:

- Soil erosion and pollution along the road route due to the meteoric water flowing down on road embankments;
- Soil degradation along the route due to works for road embankments maintenance;
- Accidental, incidental, and seasonal soil pollution from:
    - Spreading on and infiltration of pollutant substances following the traffic accidents or failures (especially but not only in the liquid freight transport), incidental discharges of substances used for road maintenance, and snow-melt containing de-icing chemicals or sand;
    - Deposition of traffic-related pollutant substances (SO_2, NO_x, and heavy metals) from rain and snowfall.

In addition, deicing agents used in colder winter conditions and herbicides for vegetation management along the right-of-way may also be sources of potential soil contamination during the operation phase.

VI.4. Mitigation Measures

Mitigation measures to be taken for the protection of soils and minimization of geological/geotechnical risks during the land preparation and construction and operation phases of the Project is described below. The strategy will primarily adopt KGM's technical specifications, which are based on well-established practices developed in line with the relevant international standards and guidelines.

An Emergency Preparedness and Response Plan (see Annex-4) have been developed for the Project. In addition to the measures described in this chapter, appropriate measures will be taken in case of soil contamination incidents in accordance with this Plan.

VI.4.1. Land Preparation and Construction Phase

Mitigation measures to be taken to avoid and/or minimize impacts on soil environment during the land preparation and construction phases of the Project are described below. Topography was one of the most critical environmental criteria considered in the route selection process. It has been aimed that the route and the motorway design conforms with the existing topographical conditions to the maximum extent possible. To avoid the extraction of additional material from quarries/material borrow sites and increased interaction with the topography, excavated materials will be reused wherever the quality and quantity of the material are adequate. Further planning will be done to identify the source of the additional material extraction and storage site requirements. Necessary assessments will be conducted for other sites to be identified outside of the Supplementary ESIA study corridor.

Measures to be taken to Minimize Soil Disturbance

To minimize soil disturbance, the area of both temporary work sites and permanent Project components will be limited. For this purpose, work sites will be properly bordered (fencing, marking, etc.), and the construction personnel will be trained not to breach these predetermined borders. Additionally, drivers of the construction machinery and equipment will also be trained to use only designated routes to minimize soil disturbance. Other project-specific measures to be taken in each relevant subject are further described below.

Topsoil Management

Stripping and Temporary Storage of Topsoil

Before the commencement of construction activities, fertile topsoil present at the Project area (motorway route, quarry/material borrow sites, storage sites, etc.) will be stripped to sufficient depth (typically around 20-30 cm depending on local soil conditions). This stripped topsoil will be stored separately from subsoil and other coarse materials in designated topsoil storage areas along the route (within the expropriation corridor) or other work sites under suitable conditions for the conservation of its vegetative properties. The following procedures will be followed in accordance with KGM's Technical Specifications and industry best practices for topsoil stripping and storage practices:

- Stripping will not be conducted on wet soil to prevent compaction.
- Seeds, tubers, and rhizomes that can be reused in rehabilitation works will be collected and stored separately.
- The average height of topsoil stacks will be 1.5 meters. The side slope of the stacks will not exceed 3:1 ratio (h:v).
- Drainage will be provided via open channels, and the top of the stacks will be mildly compressed to minimize rainwater infiltration without creating anaerobic conditions.
- Berms will be constructed around the stacks to protect against flooding, if/where necessary.
- In case of long term storage of the topsoil, soil compaction and reduction in organic content of the soil may occur. Thus, soil stacks will be temporarily planted with legumes or grasses to maintain organic content of the topsoil if the topsoil is planned to be stored more than three months.
- Organic (grass, etc.) or inorganic (polyethylene, etc.) covers will be applied to improve its quality, prevent erosion, and avoid desiccation or invasion of wild herbs.

Reinstatement of Topsoil

Topsoil stripped and stored in suitable conditions will be reused in the rehabilitation of temporary construction sites upon completion of construction activities, on the finalization of side slopes and/or in landscaping activities. The following procedures will be followed in accordance with KGM's Technical Specifications and industry best practices for topsoil stripping and storage practices:

- Prior to the reinstatement of topsoil, the subsoil will be loosened either manually or using machinery to a depth of 15 cm. For compacted or heavy clay soils, this depth will be increased to 40-50 cm.
- Following the loosening operation, the ground will not be leveled to ensure a rough surface, which is more favorable for the absorption of topsoil.
- The average depth of topsoil reinstated on regular lands will be 15 cm. The depths for specific planting areas will be:
  - Side slopes : 10 cm
  - Germinated areas : 15 cm
  - Shrub plantation areas : 45 cm
  - Tree roots : 70 cm
- After reinstating the topsoil, grading operations will be conducted in accordance with natural slope and drainage conditions. Stones, grass, and any undesirable materials will be removed as much as possible, and the land will be prepared for planting operations.

The combined thickness of the topsoil and the vegetative growth layer will be restored to a level not less than that of the undisturbed areas.

Soil Erosion Minimization and Control

The following procedures will be followed in accordance with KGM's Technical Specifications and industry best practices for topsoil stripping and storage practices:

- Erosion control measures (e.g., geotextile filter barriers that would reduce the flow velocity and trap the sediments, drainage channels, settling structures, etc.) will be implemented along the route prior to the start of construction works in order to reduce or prevent off-site sediment transport during construction. Temporary erosion control measures will be adjusted and relocated as the construction progresses.
- Mulching will be applied to stabilize exposed areas, where stripping and excavation works will be planned.
- Activities will be adapted/modified or suspended during extreme rainfall and high winds to the extent practical.
- Contouring will be applied to reduce the length and steepness of slopes, minimizing erosion potential.
- All the earthworks will be structured regularly as frequently as necessary to control probable surface run-off due to precipitation and minimize associated erosion.
- All the water flow coming from the areas surrounding the worksites and from the side slopes will be diverted by means of temporary channels, earth banks and temporary engineering structures to avoid mixing of clean (non-contact) and contaminated (contact) runoff.
- Erosion control measures will be implemented at the outlet of culverts.
- At the outlet of the erosion control structures, relevant measures (i.e., use of riprap) will be taken to reduce the flow velocity and erosion impact.
- Following the completion of base excavations, permanent erosion control measures will be taken, and slope improvement works will be conducted.
- Dikes will be formed around the excavated material storage sites in order to prevent the loss of soil due to erosion.
- Channels and ditches will be designed in consideration of post-construction flows.
- Following the completion of the concrete lining of the drainage ditches, temporary erosion control structures will be dismantled, and the sites will be rehabilitated.
- Temporary service road gradients will be limited to reduce runoff-induced erosion.
- All the worksites will be revegetated to the extent possible promptly following the completion of works at that site.

Avoidance and Minimization of Soil Contamination Risk

Oil, fuel, dye and other hazardous substances may spill or leak at the construction sites during transportation, storage, preparation, or use. Training will be provided to the personnel working with such substances to minimize the risk of accidents. For accidents that cannot be avoided by taking relevant measures, immediate response measures will be implemented in accordance with the Emergency Preparedness and Response Plan (Annex-4 of this report) in order to prevent dispersion of contamination. The actions to be taken to avoid and/or minimize soil contamination are as follows:

- Any substance/material that may cause soil contamination will not be allowed to be discharged into the soil environment;
- Any spills or leaks will be responded in accordance with the procedures described in the Emergency Preparedness and Response Plan (Annex-4);
- Properly maintained construction machinery and equipment (preferably also with lower polluting engines) will be used to minimize deposition of air pollutants on soils;
- Wastes and wastewaters generated by Project activities will be properly managed in line with the requirements of national legislation as well as IFC EHS Guidelines as described in detail in Chapter 7 ("Use of Resources and Wastes") and Chapter 8 ("Water Resources"). Measures will be taken to prevent uncontrolled waste and wastewater from contacting the soil environment.
- Hazardous wastes and materials (such as diesel, fuel oil, degreasers, and solvents) will be handled in designated areas in accordance with the Hazardous Wastes Management Procedure developed as a part of the project-specific Environmental and Social Management Plan (Annex-1). In this respect, contact of hazardous wastes and materials with soil resources will be prevented by taking relevant measures (e.g., storage on the impervious ground, personnel training).

Management of Contaminated Lands

Management of contaminated lands is essential to avoid risks on human health and ecology. When contamination of land is suspected or confirmed during any phase of the Project, the cause of the uncontrolled release will be identified and actions will be taken to avoid further releases and associated adverse impacts. The following measures will be taken:

- Relevant provisions of the Turkish Regulation on the Soil Pollution Control and Sites Contamination by Point Sources, which are aligned with IFC's risk assessment and management approach for the contaminated lands, will be complied with to manage potentially contaminated sites. Coordination with local authorities will be established for the identification and management/remediation of the sites.
- Construction personnel will receive training on the identification and management of potentially contaminated sites. In case of an encounter, local authorities will be informed, and their guidance will be followed for site management. Measures will be designed on a case-by-case basis, depending on the scale and content of the contamination.

Geotechnical Safety

Mitigation measures will be taken to minimize geotechnical risks such as ground instability/ground movement, landslides, different groundwater levels and erosion during the construction phase of the Project.

VI.4.2. Operation Phase

Although operation activities will not directly impact topography and soils, mitigation measures will be taken to minimize and control potential soil erosion risks, particularly at the embankment areas, topsoil storage areas, exposed soils, and quarry sites. If not properly managed, these areas may remain vulnerable. Similarly, emergency preparedness and response measures will be maintained to address

soil contamination risks from potential road accidents, repair and maintenance works and activities in repair and maintenance, and operation centers as well as service areas. Similarly, the effectiveness of the design measures taken against geological and geotechnical risks will be ensured throughout the operation phase by taking the necessary management measures. Measures to be taken during the operation phase are detailed under the following subsections.

Soil Erosion Control during Operation

- Soil erosion during road operation will be prevented or minimized through timely strengthening/reinforcement and rehabilitation of the road, with scheduling adjustments during periods of heavy rainfall.
- Weekly inspections will be conducted on all erosion control structures. In the event of precipitation exceeding 10 mm within 24-hour period, on-site checks will be carried out to assess the condition of these structures, and maintenance will be performed as needed.
- Embankment and cutting slopes will be checked by qualified personnel at least once a year (preferentially after spring) to identify potential risks related erosion, landslide, or instability.
- Erosion control structures will be cleaned when half of their capacity is filled with sediment. Damaged or malfunctioning structures will be rebuilt or repaired.
- Stormwater management measures designed to slow peak runoff flow, reduce sediment loads, and increase infiltration, such as salt resistant vegetated swales, terracing, detention ponds, and basins, will be kept functional.
- Proper erosion and sediment control measures will be implemented during road paving works to reduce runoff at repair sites.
- Afforestation activities will be conducted according to the Afforestation Plan (will be added as an Annex) to minimize large scale erosion risks.

Soil Contamination Avoidance/Minimization and Response

- Against the risk of soil pollution due to road accidents that may result in the spill of hazardous liquids or substances on the road surface and surrounding areas, actions defined in the Emergency Preparedness and Response Plan (Annex-4) will be implemented.
- Low polluting de-icing products will be used in the scope of the deicing operations. Additional measures defined in Chapter 8 (“Water Resources”) for the road deicing operations will also contribute to the protection of soil resources.
- Treated effluents and wastes from the operation and maintenance centers as well as services areas will be discharged or disposed of in accordance with the requirements of the national legislations and IFC’s EHS Guidelines. Relevant measures for waste and wastewater management are described in Chapter 7 (“Use of Resources and Wastes”) and Chapter 8 (“Water Resources”).

Geotechnical Safety

In the design of the engineering structures, Standard Specifications for Highway Bridges published by the American Association of State Highway and Transportation Officials (AASHTO) has been used. In the seismic calculations, the Standard Specifications used for the seismic design of the highway

bridges have been taken as a basis. Where required, project-specific revisions have been and will be done as necessary with the approval of KGM to adequately adapt these specifications to the Project.

Foundations, viaduct (Viaduct-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15-16) supports, and bridges (K-1-2-3-4-5-6-7-8-9-10-11-12-13-14-15-16-17-18-19-20-21-22) as well as other critical structural elements will be controlled by qualified technical personnel at least once a year (preferably in April) to detect any structural movement, undermining, maintenance needs, etc. that may pose risks to the durability of the structures and take the relevant corrective measures.

In the event of natural disasters (i.e., earthquakes) that may risk the structural safety of the Project structures, the operation personnel will conduct visual inspections, take immediate actions (e.g., communication with local people, restricting access to risky areas, etc.) and coordinate with local emergency response authorities to ensure public health and safety of the local people and protect the Motorway and its users.

VI.5. Summary of Assessments and Residual Impacts

Table VI.24 provides a summary of the assessments for impacts on topography, soils, and geology. The significance of the effects identified before and after the implementation of mitigation measures are summarized in this table. As shown, potential impacts on the relevant environmental components are anticipated to be reduced to low levels in the long run with effective implementation of mitigation measures, except the changes in the topography. It should be noted that some mitigation measures, such as erosion control or afforestation, require time (ranging from months to years) to show their effectiveness and ensure that the residual impacts are adequately mitigated to acceptable levels. Erosion and soil contamination risks are manageable by trained personnel through well-established site management plans. Thus, once the mitigation measures described in the ESIA Report are implemented, no significant risk would be posed by the construction and operation activities of the Project. In regard to seismic and geotechnical risks, strict adherence to international and national standards is essential in the design of the Motorway. This ensures that residual impacts are reduced to acceptable levels, thereby preventing unacceptable consequences that could jeopardize the health and safety of nearby communities and motorway users while preserving the structural integrity of the motorway during seismic events.

Table VI.24. Summary of the Topography, Soils and Geology Assessments

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Land Preparation and Construction Phase												
Change of existing topographical conditions due to cut and fill operations, Disturbance of soils.	Topography and Soils: Natural topograpghy.	Adverse	Restricted	Long	High (for linear Project with 117.8 km length, 100 - 350 m expropriation corridor) Excavation: 43.8 mi. m^3 Fill: 42.3 mi. m^3	Irreversible	One-off	Medium (B)	Moderate (2)	Medium (B2)	• Motorway have been designed and will be constructed in conformity with the existing topographical conditions to the maximum extent possible. • Excavated materials will be reused whereever the quality and quantity of the material is adequate, to avoid extraction of additional material from quarries/material borrow sites. Further planning will be done to identify the source of the additional material extraction and storage site requirements. Necessary assessments will be conducted for additional sites to be identified outside of the Supplementary ESIA study corridor. • Working sites will be bordered by means of proper methods (i.e. fencing, marking, etc.) and construction workforce will be informed about not breaching the predetermined borders. • Drivers of the construction machinery and equipments will be trained to use only prescribed routes to minimize the area to be physically interacted.	Medium
	Topography and Soils: Already distrubed topograpghy.	Adverse	Restricted	Long	High (for linear Project with 117.8 km length, 100 - 350 m expropriation corridor) Excavation: 43.8 mi. m^3 Fill: 42.3 mi. m^3	Irreversible	One-off	Medium (B)	Low (1)	Low (B1)		Low
Risk of loss of quantity and quality (e.g. vegetative structure) of top soil.	Topography and Soils: Agricultural areas.	Adverse	Restricted	Long	High (for linear Project with 117.8 km length, 100-350 m expropriaton corridor)	Long term reversible	Continuous	Medium (B)	High (3)	High (B3)	Stripping and Temporary Storage of Top Soil • Prior to construction activities, fertile top soil available at the project area (Motorway route, quarry/material borrow sites, storage sites, etc.) will be stripped to sufficient depth (may change between 5 to 40 cm depending on local soil conditions) and will be stored separately from other coarse materials/soils (subsoil) at top soil storage areas to be designated along the motorway route or other work sites under conditions suitable for the conservation of vegetative properties. • To avoid soil compaction, stripping operation will not be done when soil is wet. • Seed, tuber, rhizome, situated on the top soil, which can be reused in rehabilitation works, will be collected and stored separately. • Average height of top soil stacks will be 1.5 meters. Side slope of these stacks will not exceed 3:1 (h:v). • Drainage of top soil storage areas will be provided by open channels. In order to minimize the amount of rain water that can infiltrate into the top soil stack, the upper parts of the top soil stacks will be compressed. Excessive compression can cause anaerobic conditions. Therefore, compression operations will be carried out mildly. • If it is necessary, soil stacks will be protected against the risk of floods by creating berms of adequate height. • In case of long term storage of top soil, soil compaction and reduction in organic content of the soil may occur. In this context, if the storage will last for more than three months, the upper part of fertile soil will be planted temporarily in order to conserve organic content. In planting operations, selected species of legume and grails will be used in proper seed mixture ratios.	Medium
	Topography and Soils: Forest areas.	Adverse	Restricted	Long	High (for linear Project with 117.8 km length, 100-350 m expropriaton corridor) 5.4 mi. m^3	Long term reversible	Continuous	Medium (B)	Moderate (2)	Medium (B2)		Low

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
											• Organic (grass, etc.) or inorganic (polyethylene, etc.) materials will be applied on the top soil to be stored to improve its quality and avoid erosion, desiccation or invasion of wild herbs. Reinstation of Top Soil • Top soil stripped and stored in suitable conditions will be reused in rehabilitation of temporary construction sites upon completion of construction activities, on the finalization of side slopes and/or in the scope of landscaping activities. • Sub soil will be loosened by hand or machinery to a depth of 15 cm prior to the reinstation of top soil. For compact or heavy clay soils, loosening depth is to be increased up to 40-50 cm. • Following the loosening operation, ground will not be leveled before the reinstation of top soil so that a favorable rough surface is obtained for the adsorption of top soil. • Average depth of top soil to be reinstated on regular lands will be 15 cm. • Depth of top soil for areas to be planted will be suitable for side slopes, shrub plantation areas, tree roots, etc. • Following the reinstation of top soil, grading operation will be conducted in alignment with the natural slope and drainage conditions. Any stone, grass or undesired materials will be removed to the extent possible and the land will be prepared for the upcoming planting operations. • Combined thickness of topsoil and the vegetative growth layer will not be less than that prevailing in the undisturbed areas.	

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Erosion of soils due to earthworks.	Topography and Soils.	Adverse	Restricted	Long	High (assummed for the linear Project with 117.8 km length, 100-350 m expropriation corridor. The amount of material to be mobilized will depend on the construction technique)	Medium term reversible	Continuous	Medium (B)	High (3)	High (B3)	• Erosion control measures (e.g. geotextile filter barriers that would reduce the flow velocity and trap the sediments, drainage channels, settling structures, etc.) will be implemented along the route prior to the start of construction works in order to reduce or prevent off-site sediment transport during construction. Temporary erosion control measures will be moved forward as the construction progresses. • Stripping and excavation works will be planned in a way that maximum 30.000 m2 of exposed land will be created at once. Mulching will be applied to stabilize exposed areas. • Activities will be modified or suspended during extreme rainfall and high winds to the extent practical. • Contouring will be applied and length and steepness of slopes will be minimized. • All the earth works will be structured at the end of each work day in a way to control probable surface run-off due to precipitation and minimize associated erosion. • All the water flow coming from the areas surrounding the work sites and from the side slopes will be diverted by means of temporary channels, earth banks and temporary engineering structures to avoid mixing of clean (non-contact) and contaminated (contact) runoff. • Erosion control measures will be implemented at the outlet of culverts. • At the outlet of the erosion control structures, relevant measures (i.e. use of riprap) will be taken to reduce the flow velocity and erosion impact. • Following the completion of base excavations, permanent erosion control measures will be taken and slope improvement works will be conducted. • Dikes will be formed around the excavated material storage sites in order to prevent loss of soil due to erosion. • Channels and ditches will be designed in consideration of post-construction flows. • Following the completion of concrete lining of the drainage ditches, temporary erosion control structures will be dismantled and the sites will be rehabilitated. • Temporary service road gradients will be limited to reduce runoff-induced erosion. • All the work sites will be revegetated to the extent possible promptly following the completion of works at that site. • Operation and Rehabilitation of Quarries and Material Borrow Sites • Open pit mining method will be used at quarries and tunneling will not be applied. Open pit will be developed in benches. • Borders of the quarry and material borrow sites will be identified by using proper methods (i.e. fencing, etc.) and material extraction activities will be conducted within these borders. • During the operation of the quarries and material borrow sites; runoff from rain will be diverted from the face of the slopes, which are exposed in the excavation process. The runoff will then be conveyed in channels to stable disposal points. • Quarries and material borrow sites will be rehabilitated following the completion of material extraction activities.	Medium
Risk of soil contamination due to accidental spills, leakages, etc.	Topography and Soils: Agricultural areas, pastures, and forests.	Adverse	Restricted	Medium	Medium	Short term reversible	One-off	Restricted (C)	High (3)	Medium (C3)	• Emergency Preparedness and Action Plan will be implemented. • Any substance/material that would result in soil contamination will not be allowed to be discharged onto soil environment. • Any spill or leakage event will be responded in accordance with the procedures described in the Emergency Preparedness and Response Plan • Proper construction machinery and equipment endowed with low polluting engines will be used to minimize deposition of air pollutants on soils. • Wastes and wastewaters to be generated as a result of project activities will be properly managed in line with the requirements of national legislation as well as IFC EHS Guidelines. In this context, direct contact of the uncontrolled wastes and wastewaters with soil environment will be avoided by taking relevant measures.	Low
	Topography and Soils: Vegetated areas, recreational	Adverse	Restricted	Medium	Medium	Short term reversible	One-off	Restricted (C)	Moderate (2)	Low (C2)		Low

VII. USE OF RESOURCES AND WASTE MANAGEMENT

As with other infrastructure projects, materials such as rock, sandstone, limestone, basalt, etc. as well as concrete, steel, aggregates, asphalt, etc. will be used in significant quantities during the construction works of the Project. Additionally, the Project will require the procurement of construction materials from quarries and other suppliers for materials needed for the operation phase activities and maintenance works to be conducted in the operation phase. As a result, the use of resources and other construction and operation/maintenance activities as well as the domestic/municipal requirements of the personnel and the users of the Motorway, will generate different types of wastes throughout the life of the Project. All the waste to be generated during the construction and operation phases of the Project are required to be properly managed in line with the requirements of national waste management legislation and international good practice in order to avoid impacts on soils, nearby water resources and flora and fauna elements. This chapter identifies the resources to be used in this context and assesses the impacts associated with waste generation. Waste management measures to be applied in accordance with relevant Turkish regulations and international standards (i.e. IFC's General EHS Guidelines) are also described in this chapter. Potential impacts of material supply and waste generation on soil and water resources, ecological components and socio-economic environment are discussed in the relevant chapters of this report.

VII.1. Assessment Methodology and Data Sources

To assess the impacts associated with the use of resources and waste generation, information provided by the Project Sponsor on the quarries, borrow pits, construction campsites, etc. has been reviewed. To understand the existing waste management infrastructure of the region, public information given in the web site of Antalya Metropolitan Municipality has been relied on. For the calculations of the amount of municipal solid wastes, waste statistics published by TurkStat (2022) have been considered, together with the maximum number of personnel to be employed.

Significance Criteria

The significance criteria for the impacts on land use and property are determined, as high, medium or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter IV ("ESIA Methodology") is used for the determination of the magnitude of impact on the land use components, sensitivity/value criteria to be used in the scope of impact assessment is summarized in Table VII.1.

Table VII.1. Criteria for Sensitivity/Value of Resource/Receptor

Resource/Receptor	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Local waste infrastructure	If the local waste infrastructure has not sufficient capacity; landfills do not meet the requirements of the regulations.	If the local waste infrastructure has sufficient capacity; but there are some shortcomings in meeting the regulations or capacity may be stressed under high-load conditions.	If the local waste infrastructure has sufficient capacity; landfills meet the requirements of the regulations.

VII.2. Baseline Conditions

VII.2.1. Quarries and Material Borrow Sites

The mining sector in Antalya primarily based on marble, limestone and barite extraction. Marble and limestone are mainly utilized in the construction sector for building materials and landscaping. Barite, used in various sectors, is predominantly employed in the production of paint, paper and rubber. Due

to their economic value, these products, especially marble, are significant export commodities. Additionally, there are a few travertine mines in Antalya. Mineral map of Antalya province is presented in Figure VII.1.

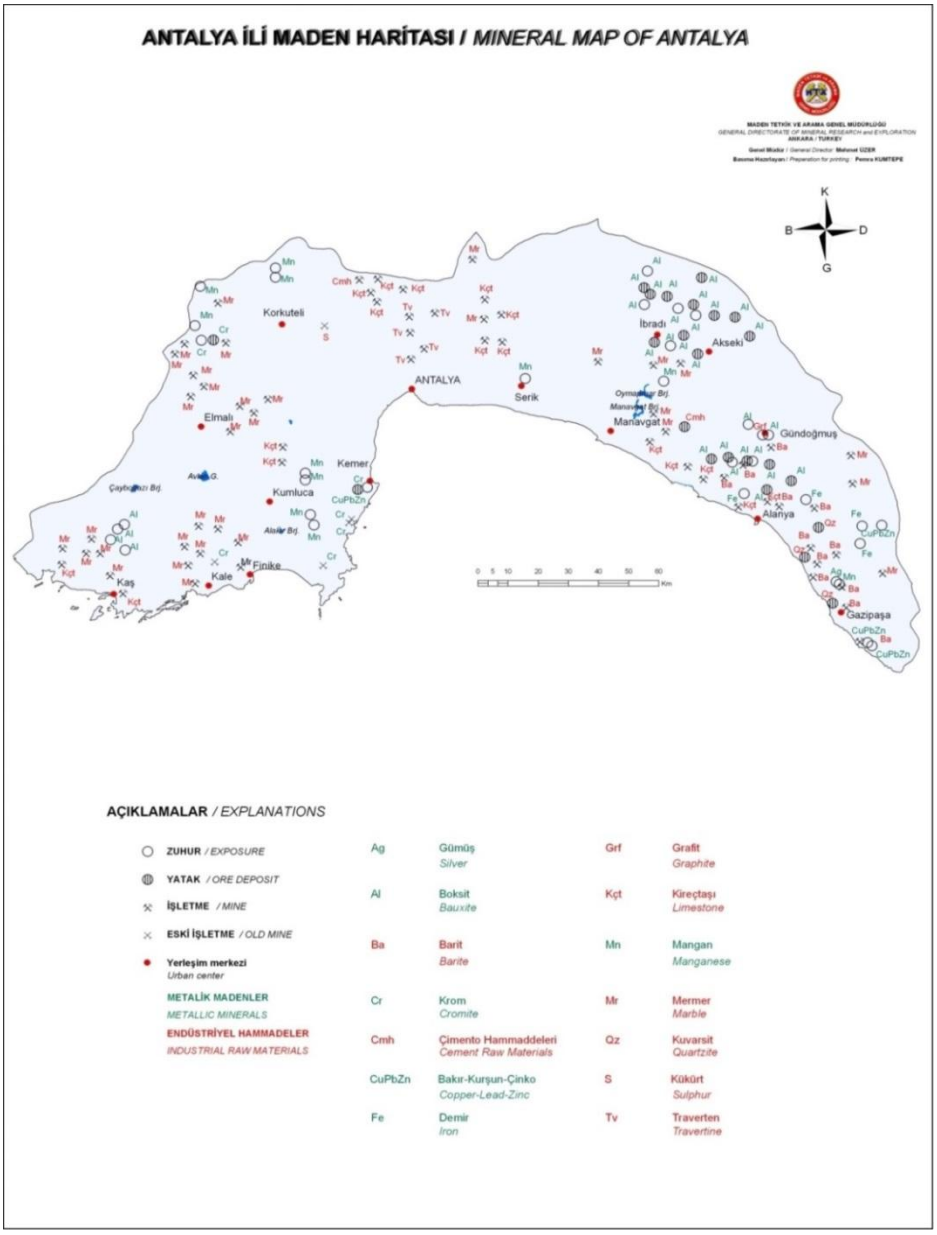

Figure VII.1. Mineral Map of Antalya[1]

[1] *www.mta.gov.tr*

According to the provided map above, there are 34 marble, 17 limestone, 11 barite, 5 travertine and one cement additive mines are present in Antalya province. Types of mining groups and their descriptions according to the Mining Law are provided in Table VII.2.

Table VII.2. Types of Mining Groups and their Description

Group No	Description of the Group in the Mining Law
I-A Group	Sand and gravel
I-B Group	Brick-tile clay, cement clay, marn, tras, and other rock materials used in cement and ceramic industries
II-A Group	Rock material used for producing aggregate, ready-made concrete and asphalt from calcite, dolomite, limestone, granite, andesite, basalt
II-B Group	Stones produced as stone as marble, travertine, granite, andesite, basalt
II-C Group	Rock material used in producing cement, chalk, and calcite from dolomite, limestone, granite, andesite, basalt
Group III	Salts, carbondioxide (geothermal, natural gas and oil sites excluded), hydrogen sulfur (secluding 07/03/1954 dated and 6326 numbered Oil Law), dissolved in sea, lake and spring water,
Group IV	Lignite, coal, gold, silver, copper, zinc, chromium, iron, cobalt, nickel, aluminum, trona, sulphur, etc.
Group V	Diamond, sapphire, opal, amazonite, etc.

Source: Mining Law Numbered 3213 (Amended: 04/02/2015 – 6592/1)

In the scope of the Project, two quarries are planned to be used to supply the material requirements. These quarries have raw material production licenses. Additionally, two borrow pits and another quarry to be opened will be utilized in the Project (Table VII.3).

Table VII.3. Raw Material Extraction Sites to be used in the Project

Quarry Site	Area (ha)	Operation Duration (months)	Type of Raw Material to be Extracted	Capacity (m^3/h)
Sarıabalı Borrow Pit*	24.9	36	Crystallized limestone, marble/To be analyzed	375
Çakış Quarry (TOY4*a)	24.7	36	Crystallized limestone, marble/To be analyzed	375
Kuruçay Quarry (TOY4a Alternative)	24.3	36	Crystallized limestone, marble/To be analyzed	375
Dikmen Quarry**	24.4	36	Crystallized limestone, marble/To be analyzed	375
Bademliyar Quarry (TO2)	17.8	36	Crystallized limestone, marble/To be analyzed	375
Çenger Bourn Stream Material Quarry*	19.0	36	Crystallized limestone, marble/To be analyzed	375
Uzunlar Quarry (TOY5)*	24.6	36	Crystallized limestone, marble/To be analyzed	375
Karakaya Quarry	24.9	36	Crystallized limestone, marble/To be analyzed	375
Saburlar Quarry	24.9	36	Crystallized limestone, marble/To be analyzed	375
Karamanlar Quarry*	31.2	36	Crystallized limestone, marble/To be analyzed	375
Soğukpınar Quarry	25.1	36	Crystallized limestone, marble/To be analyzed	375

*Most likely to be utilized
**It will not be utilized as the connection to Manavgat has changed.

VII.2.2. Existing Waste Management Infrastructure in the Region

Municipal Solid Waste

There are four landfills in Antalya province. Their names are Patara Solid Waste Landfill, Manavgat Solid Waste Energy Recovery and Landfill Facility, Alanya Integrated Solid Waste Recycle and Disposal Facility, and Kızıllı Integrated Solid Waste Recycle and Landfill Facility (see Table VII.4). Generated solid wastes are collected by the waste trucks of district municipalities, transferred to one of the six solid waste transfer stations, and disposed of at these landfills, which are designed in accordance with the requirements of the Regulation on the Landfill of Wastes. In this context, landfills have proper impermeability layers and the leachate collected at the landfills is treated by means of physical, chemical, and anaerobic processes. In the province, treated wastewater is discharged into the sewerage system of the Antalya Water and Wastewater Administration (ASAT) (Antalya Province Environmental Status Report, 2022). For the wastewater management of the Project, package WWTPs are planned to be used in the campsites during the construction phase.

Table VII.4. Landfills and Transfer Stations in Antalya Province

Landfills
Patara Solid Waste Landfill
Manavgat Solid Waste Energy Recovery and Landfill Facility
Alanya Integrated Solid Waste Recycle and Disposal Facility
Kızıllı Integrated Solid Waste Recycle and Landfill Facility
Transfer Stations
Elmalı Transfer Station
Kumluca Transfer Station
Serik Transfer Station
Kemer Transfer Station
Korkuteli Transfer Station
Manavgat Transfer Station
Facilities in Construction, Permitting and Commissioning Stages
Demre Transfer Station
Gazipaşa Transfer Station

Source: Antalya Province Environmental Status Report, 2023

The closest and appropriate landfills would be identified and used for the management of Project-sourced wastes. Required agreements will be made with the municipalities and the facilities for the transfer, recovery, disposal and landfill services.

Municipal Wastewater

There are 35 wastewater treatment plants (WWTPs) in Antalya province[2]. All of the WWTPs are designed as either biological treatment or advanced treatment systems. 16 of these plants discharge their treated water into suitable water bodies while 19 of them are utilizing deep sea discharge. Package WWTPs will be constructed in each campsite to treat the domestic wastewater that will be generated during the construction phase of the Project. The total equivalent population for these plants is 3.750 people. A total of 3.300 people will be accommodated across three campsites as part of the Project. It is assumed that approximately 1,100 people will stay at each campsite. Considering potential visitors and occasional overcapacity, a package WWTP with a capacity for 1,250 people is calculated to be sufficient for the domestic wastewater treatment needs of each campsite.

Construction, Demolition Wastes and Excavated Soil

There is only one construction and demolition waste disposal site in Antalya to manage excavation, construction and demolition wastes, in Karaöz Street of Kızıllı Neighborhood. In the year 2023, the site collected 3.2 million m^3 of excavation waste and 1.3 million m^3 of construction and demolition waste. Antalya Metropolitan Municipality issues licenses for the transportation of the construction and demolition wastes produced in the city. The transportation of these wastes is carried out by licensed vehicles/trucks within the city, and the wastes are disposed of in the area designated by the Municipality (Antalya Province Environmental Status Report, 2023).

Packaging Waste

As of 2023, 25 packaging waste facilities have the relevant environmental permits and licenses in a total of Antalya Metropolitan Municipality. These facilities serve for the recovery of packaging materials including plastics, metals, composite packages, paper and cardboard, glass, and wood-produced collection and separation facilities in Antalya (Antalya Province Environmental Status Report, 2023).

Hazardous and Special Waste

Hazardous and special wastes produced in Antalya are managed by different methods including recovery, disposal, storage, export, etc. The amount of hazardous waste recorded in 2023 was 15,364 tons in the province. Non-hazardous and special wastes including waste tires, medical wastes, waste vegetable oils, waste batteries, and accumulators are managed (e.g. recovery) and/or disposed of at licensed facilities (Antalya Province Environmental Status Reports, 2023).

Regarding the management of hazardous wastes, the province has two hazardous waste recovery facility providing services in the field of hazardous waste recovery, disposal, landfill and exportation. In 2023, 11,096 tons of waste was recovered, 4,064 tons were sent for disposal, 205 tons collected for storage (Antalya Province Environmental Status Report, 2023).

Medical Waste

Medical wastes produced in the province are collected by medical waste transportation vehicles and disposed of at the licensed medical waste sterilization facility. As of 2023 there is one such facility in the province that is operating 6 medical waste transportation vehicles. A total of 3,458 tons of medical

[2] *Antalya Province Environmental Status Report, 2023*

waste was collected from a diverse set of businesses, institutions and facilities, including 47 hospitals, 297 polyclinics, 37 laboratories, 12 dialysis centers, 444 dentists 458 tourism businesses and 17 municipal service buildings operating in the province (Antalya Province Environmental Status Report, 2023).

Vegetable Oil Waste

There are 10 licensed interim storage facilities for waste vegetable oil; however, the province lacks a waste vegetable oil recovery facility. The amount of waste vegetable oil collected in Antalya was recorded as 1,520 tons (Antalya Province Environmental Status Report, 2023).

Waste Tire

There is a one licensed waste tire recovery facility and one waste tire recycling facility in the province for the management of waste tires. A total of 20 tons of waste tires were sent to recovery (energy recovery by incineration) facility, while 231 tons were processed by the waste tire recycling facility (Antalya Province Environmental Status Report, 2023).

Waste Batteries and Accumulators

There is one licensed waste accumulator recycling facility and nine temporary waste accumulator storage facilities in the province. The amount of waste accumulators and waste batteries collected in the province was 538 tons (Antalya Province Environmental Status Report, 2023).

VII.3. Potential Impacts

As with other infrastructure projects, materials such as rock, sandstone, limestone, basalt, etc. as well as concrete, steel, aggregates, asphalt, etc. will be used in significant quantities during the construction of the Project. In the operation phase, use of materials will be limited with the maintenance activities to be conducted at the road, operation and maintenance centers and fuel stations. In addition to those mentioned raw materials, chemical materials will also be used for the Project. The names, properties and Material Safety Data Sheets (MSDS) of some of the chemicals that will be used have been identified by the Project Sponsor.

Different types of wastes (hazardous, non-hazardous or inert) will be generated as a result of the materials used and personnel requirements during the land preparation and construction, and operation activities. As use of construction materials and personnel involvement will be at significant levels during the construction phase, waste generation will be a more important issue when compared to operation phase. Types of wastes to be generated in each phase are identified in the following sections, with quantification for certain types of wastes (i.e. municipal, excavated materials) wherever possible.

If not properly managed, waste generation may cause soil contamination, pollution of surface and groundwater resources, and disturbance of flora and fauna components, visual nuisance and risks to public and personnel health and safety. Adverse impacts on ecosystem components including soil, surface and ground water resources as well as flora and fauna components and other social issues associated with waste generation can be avoided and/or minimized with effective implementation of

good waste management practices in accordance with the requirements of national legislation and international standards.

VII.3.1. Land Preparation and Construction Phase

During the construction works, temporary facilities/sites will be needed. These facilities and sites include construction campsites, quarries, borrow pits, plants and service roads. Following the completion of construction activities, temporary facilities will be decommissioned. Table VII.5 provides a list of the campsites, quarries and plants to be used in the scope of the Project.

Table VII.5. Locations of the Quarries, Plants and Storage Sites

Location		Description of the Site / Quarry / Plant	Area (ha) / Capacity Information (m^3)
Mechanical Plants			
Km 59+400	Antalya, Manavgat	Mechanical Plant-1	6.65 ha (550 tonnes/hour)*
Km 87+700	Antalya, Manavgat	Mechanical Plant-2	4.24 ha (550 tonnes/hour)*
Km 124+300	Antalya, Alanya	Mechanical Plant-3	8.50 ha (550 tonnes/hour)*
Asphalt Plants			
Km 59+400	Antalya, Manavgat	Asphalt Plant-1	6.65 ha (240 tonnes/hour)*
Km 87+700	Antalya, Manavgat	Asphalt Plant-2	4.24 ha (240 tonnes/hour)*
Km 124+300	Antalya, Alanya	Asphalt Plant-3	8.50 ha (550 tonnes/hour)*
Concrete Plants			
Km 55+450	Antalya, Serik	Concrete Plant-1	1.40 ha (140 m^3/hour)
Km 59+400	Antalya, Manavgat	Concrete Plant-2	6.65 ha (140 m^3/hour)*
Km 80+400	Antalya, Manavgat	Concrete Plant-3	1.50 ha (140 m^3/hour)
Km 87+700	Antalya, Manavgat	Concrete Plant-4	4.24 ha (140 m^3/hour)*
Km 89+700	Antalya, Manavgat	Concrete Plant-4a	1.17 ha (140 m^3/hour)
Km 99+200	Antalya, Manavgat	Concrete Plant-5	1.20 ha (140 m^3/hour)
Km124+300	Antalya, Alanya	Concrete Plant-6	8.50 ha (140 m^3/hour)*
Construction Sites			
Km 64+500	Antalya, Manavgat	Construction Site-1 (Main)	10.00 ha
Km 87+500	Antalya, Manavgat	Construction Site-2	3.80 ha
Km 1124+300	Antalya, Alanya	Construction Site-3	8.50 ha
Quarry Sites			
Km 53+800	Antalya, Serik	Sarıabalı (AO-1) Borrow Pit	24.9 (375 m^3/hour)
Km 56+500	Antalya, Serik	Çakış (TOY4a) Quarry	24.7 (375 m^3/hour)
Km 58+500	Antalya, Serik	Kuruçay (TOY4b) Quarry	24.3 (375 m^3/hour)
Km 83+000	Antalya, Manavgat	Dikmen Borrow Pit	24.4 (375 m^3/hour)
Km 104+750	Antalya, Manavgat	Bademliyar (TO2) Quarry	17.8 (375 m^3/hour)

Location		Description of the Site / Quarry / Plant	Area (ha) / Capacity Information (m^3)
Km 105+000	Antalya, Manavgat	Çenger Stream Material Quarry	19.0 (375 m^3/hour)
Km 106+000	Antalya, Manavgat	Uzunlar (TOY5) Quarry	24.6 (375 m^3/hour)

Km 132+720	Antalya, Alanya	D-30	3,307,202.05 m^3

**The areas are given as the sum of the respective concrete, asphalt and mechanical plant areas.*

Wastes anticipated to be generated at the campsites and other worksites during the construction phase of the Project would mainly include cleared vegetation, municipal (domestic) solid wastes, domestic wastewater, treatment sludge, packaging wastes, excavation wastes, construction wastes, debris from settling ponds at concrete plants, hazardous wastes (including packaging wastes that contacted with hazardous substances), waste oils, waste tires, waste vegetable oils and other types of special wastes. Further information on the main types of wastes anticipated to be generated in the scope of land preparation and construction activities are provided below.

Waste Management Regulation includes a list of wastes as an appendix. In this list, hazardous wastes are marked with an asterisk (*) along with one of the letters (A) or (M). Letter (A) refers to wastes that will be directly categorized as hazardous, while (M) refers to wastes for which hazardousness characteristics will be determined through analyses conducted in accordance with the Regulation.
An indicative list of waste types that are anticipated to be generated during land preparation and construction activities, taken from the waste list in the annex of the Waste Management Regulation, is given in

Table VII.6. The waste codes are as specified in the Regulation and remarks column indicates the hazardousness classification of the wastes as described in the previous paragraph.

Table VII.6. Indicative List of the Potentially Generated Wastes Types During the Land Preparation and Construction Activities

Waste Code	Waste Code Definition	Remarks
01	Wastes Generated During the Exploration, Extraction, Operation and Physical or Chemical Processing of Ores	
01 01	Wastes generated due to mining excavations	
01 01 02	Wastes due to non-metallic ores	
01 04	Wastes from physical and chemical processing of non-metallic minerals	
01 04 07*	Wastes containing dangerous substances from the physical and chemical processing of non-metallic minerals	M
01 04 09	Waste sand and clays	
01 04 13	Wastes from stone chipping and cutting operations other than those mentioned in 01 04 07	
01 04 99	Wastes that not otherwise specified	
13	Oil Wastes and Liquid Fuel Wastes (Excluding Renewable Oils)	
13 01	Waste hydraulic oils	A
13 02	Waste engine, transmission and lubrication oils	A
13 03	Waste insulation and heat conduction oils	A
13 04	Bilge oils	A
13 05	Oil/water separator contents	A
13 07	Wastes of liquid fuels (fuel oil, diesel, gasoline, other fuels including mixtures)	A
15	Waste Packaging and Absorbents, Wiping Clothes, Filter Materials and Protective Clothing Not-Classified Under Other Waste Types	
15 01	Packaging (including packaging material collected by the municipality separately)	
15 01 01	Paper and cardboard packaging	
15 01 02	Plastic packaging	
15 01 03	Wood packaging	
15 01 04	Metallic packaging	
15 01 05	Composite packaging	
15 01 06	Mixed packaging	
15 01 07	Glass packaging	

Waste Code	Waste Code Definition	Remarks
15 01 09	Textile packaging	
15 01 10*	Packaging containing traces of hazardous materials or contaminated with hazardous materials	A
15 01 11*	Metallic packaging material containing hazardous porous solid structures (asbestos, for example), including empty pressurized containers	A
15 02	Absorbents, filter materials, wiping clothes and protective clothing	
15 02 02*	Absorbents, filter materials (oil filters if not classified in any other way), wiping clothes, protective clothing contaminated with hazardous materials	M
15 02 03	Absorbents, filter materials, wiping clothes and protective clothing excluding 15 02 02	
16	Wastes not Classified under any other Type of Waste in the List	
16 01	Wastes generated due to vehicle maintenance (excluding 13, 14, 16 06 and 16 08), end-of-life vehicles and the dismantling of end-of-life vehicles (including construction machinery) in various transportation categories	
16 01 03	End-of-life tires	
16 01 04*	End-of-life vehicles	A
16 01 06	End-of-life vehicles that do not contain liquids or hazardous substances	
16 01 07*	Oil filters	A
16 02	Electrical and electronic equipment wastes	A
16 04	Explosive wastes	A
16 06	Batteries and accumulators	A
16 10	Aqueous liquid wastes to be sent to off-site treatment	
16 10 01*	Aqueous liquid wastes containing dangerous substances	M
16 10 02	Aqueous liquid wastes other than those mentioned in 16 10 01	
16 10 03*	Aqueous concentrated substances containing hazardous substances	M
16 10 04	Aqueous concentrates other than 16 10 03	
17	Construction and Demolition Wastes (Including Excavations Conducted at Contaminated Sites)	
17 01	Concrete, brick, tile and ceramic	
17 01 01	Concrete	
17 01 02	Bricks	
17 01 03	Tiles and ceramic	
17 01 06*	Mixtures or separated groups of concrete, brick, tile and ceramic containing hazardous substances.	M
17 01 07	Mixtures or separated groups of concrete, brick, tile and ceramic, excluding 17 01 06	
17 02	Wood, glass and plastic	
17 02 01	Wood	
17 02 02	Glass	
17 02 03	Plastic	
17 02 04*	Wood, glass and plastic containing or contaminated with hazardous substances.	A
17 03	Mixtures containing bitumen, coal tar and products containing tar	
17 03 01*	Mixtures with bitumen, containing coal tar	M
17 03 02	Mixtures containing bitumen, excluding 17 03 01	

Waste Code	Waste Code Definition	Remarks
17 03 03*	Coal tar and products containing tar	A
17 04	Metals (including their alloys)	
17 04 01	Copper, bronze and brass	
17 04 02	Aluminium	
17 04 03	Lead	
17 04 04	Zinc	
17 04 05	Iron and steel	
17 04 06	Tin	
17 05	Soil (including excavations conducted in contaminated sites), stones and dredging mud	
17 05 03*	Soil and stones containing hazardous substances	M
17 05 04	Soil and stones excluding 17 05 03	
17 06 01*	Insulation materials containing asbestos	A
17 06 05*	Construction materials containing asbestos	A
17 09	Other construction and demolition waste	
17 09 01*	Construction and demolition waste containing mercury	M
17 09 02*	Construction and demolition waste containing PCB (example: filling paste containing PCB, resin-based base coating material containing PCB, coated enamelling units containing PCB, capacitors containing PCB)	M
17 09 03*	Other construction and demolition waste containing hazardous substances (including mixed waste)	M
17 09 04	Mixed construction and demolition waste, excluding 17 09 01, 17 09 02 and 17 09 03	
18	Healthcare Waste	
18 01 03*	Wastes whose collection and disposal is subject to special requirements in order to prevent infection*	A
19	Materials from waste and water treatment	
19 08 05	Sludges from urban wastewater treatment	
19 13 08	Concentrated liquids and aqueous liquid wastes due to groundwater rehabilitation, excluding 19 13 07	
20	Municipal Waste including Separately Collected Fractions (Household Waste and Similar Commercial, Industrial and Institutional Waste)	
20 01	Separately collected fractions (excluding 15 01)	
20 01 01	Paper and cardboard	
20 01 02	Glass	
20 01 08	Biodegradable kitchen and canteen wastes	
20 01 10	Clothing	
20 01 11	Textile products	
20 01 13*	Solvents	A
20 01 14*	Acids	A
20 01 15*	Alkalines	A
20 01 17*	Photo chemicals	A

Waste Code	Waste Code Definition	Remarks
20 01 19*	Pesticides	A
20 01 21*	Fluorescent lamps and other mercury-containing wastes	A
20 01 37*	Wood containing hazardous substances	M
20 01 38	Wood excluding 20 01 37	
20 01 39	Plastics	
20 01 40	Metals	
20 02	Garden and park wastes (including cemetery wastes)	
20 02 01	Biodegradable wastes	
20 02 02	Soil and stones	
20 02 03	Other non-biodegradable wastes	
20 03	Other municipal wastes	
20 03 01	Mixed municipal waste	
20 03 04	Septic tank sludge	

Source: Waste Management Regulation, Appendix-4

(*): Indicates that the waste is either potentially hazardous or hazardous waste.

(A): Indicates that the waste is a hazardous waste, there is no need for any further analysis.

(M): Indicates that the waste is potentially hazardous waste. In order to determine whether the waste is hazardous or not, an analysis is carried as stipulated in Article 11 of this Regulation.

Wastes ending with 99: Wastes ending with the six-digit waste code 99 define wastes that are not classified as hazardous or non-hazardous waste and are not otherwise defined in the list. "Waste Code Determination Hierarchy" and the provisions of Article 12 of this Regulation shall be applied in the use of this waste code.

Municipal Solid Wastes

According to the TurkStat data (2022), the average daily amount of municipal solid waste per capita in Türkiye is 1.03 kg, while this amount is 1.37 kg in Antalya. Most of the municipal solid waste generation due to the Project will be in the campsites. The amount of domestic solid waste to be produced in the campsites is estimated by multiplying the average daily municipal solid waste production per capita of Antalya province by the number of personnel employed due to the Project. The information on maximum number of personnel to be employed and estimated amount of municipal waste to be generated is summarized in Table VII.7. Assuming 20% (Ministry of Environment, Urbanization and Climate Change, 2020) of the municipal solid wastes (by weight) is formed of packaging wastes, estimated amount of packaging wastes within the total municipal wastes to be produced is also provided in the last column of the table. For the handling of municipal solid waste, licensed transportation vehicles and authorized disposal and landfill facilities operated by the municipalities will be used. Where feasible, disposal sites that are both compliant and located in close proximity to the workers' campsites will be prioritized to enhance fuel efficiency, reduce transport time, and minimize environmental impact. All waste handling practices will be carried out in accordance with applicable national regulations and good international industry practice.

Table VII.7. Estimated Solid Municipal Waste Generation of the Campsites

Number of Personnel* (cap)	Daily Municipal Waste Generation (kg/day/cap)	Daily Packaging Waste Generation (kg/day/cap)
3,300	1.37	0.27

** Maximum Project related employee number including subcontractors; provided by the Project Sponsor.*

The amount of municipal solid waste to be produced per day at the campsites is:

1.37 kg/day/cap * 3,300 cap = 4.52 ton/day

When compared to the total municipal solid waste generation of the Antalya province, which is 1,340,770 tons per year (Turkstat, 2022), the Project's contribution to solid waste generation of the province is less than one per two thousand. Additionally it should be noted that the campsites will be present for a maximum of 3 years during the construction period of the Project. Since the waste load contribution of the Project on the existing waste management infrastructure capacity is limited in both time and impact, the overall impact of the Project is determined as negligible.

Municipal Wastewater

According to the TurkStat data (2022), the average daily amount of municipal wastewater per capita in Türkiye is 197 liters, while this amount is 318 liters in Antalya province. Daily municipal water usage per capita is 229 liters in Türkiye, and 349 liters in the province. This disparity between national and regional statistics is mainly due to regional temperature differences and income sources. Antalya, located in the south of Türkiye, is significantly above of the country's average temperature statistics. As temperatures increase, the amount of water lost due to evaporation and the need for water consumption also rise. Additionally, tourism and farming are major sources of income for the province. Since the registered population does not include visiting tourists, the data does not accurately reflect the total number of people in the city. Consequently, water consumption and wastewater production statistics for the province are roughly 50% higher compared to national averages (TurkStat 2022).

According to the maximum personnel numbers in campsites, daily municipal wastewater generation and water usage are calculated below and provided in Table VII.8.

Assumptions:

1- Narrower/specialized statistics have priority over general/national ones if available.
2- It is assumed that the Project personnel in the campsites use %70 of average daily per capita water amount.

3- Water to wastewater ratio is calculated as 0.91 for the Antalya province and assumed as 0.9 for calculations.

Water Consumption:

3,300 personnel; campsite water usage ratio = 0.7; 349 liters/day/cap.

= 3,300 cap * 0.7 * 349 liters/day/cap = 806,190 liters/day = 806.2 tons/day

Wastewater Generation:

Water to wastewater ratio = 0.9

= 806,190 liters/day * 0.9 = 725,571 liters/day = 725.6 tons/day

Table VII.8. Estimated Municipal Wastewater Generation and Water Usage of the Campsites

Number of Personnel* (cap)	Daily Water Demand (L/day)	Daily Wastewater Generation (L/day)
3,300	806,190	725,571

** Maximum Project related employee number including subcontractors; provided by the Project Sponsor.*

As previously mentioned, package WWTPs will be used for domestic wastewater management during construction phase of the Project. In addition, impermeable septic tanks also will be utilized at the campsites, if/when necessary. The mitigation measures are elaborated in the VII.4. Considering the capacity of the WWTPs and other water and wastewater management systems, no significant impact is anticipated due to municipal wastewater management.

Treatment Sludge :

The total wastewater flow from all camp sites (Camp Site-1, Camp Site-2 and Camp Site-3) are approximately 0.725 m³/day. As a result of the treatment process, a small amount of sludge is generated. The sludge production rate corresponds to approximately 0.7 kg of dry solids generated per cubic meter of influent wastewater treated.

Based on this sludge yield, the daily dry sludge production is estimated as follows:

0.725 m^3/day x 0.7 kg/m^3 = 0.5075 kg/day

Therefore, approximately 0.51 kg of dry sludge is expected to be produced daily from all camp sites combined.

The generated sludge will be collected and removed regularly by licensed waste transport vehicles, ensuring proper handling and disposal in accordance with applicable environmental regulations and standards.

Dust Suppression:

To control and minimize fugitive dust emissions during the construction phase of the highway project, dust suppression by water spraying is planned along the main access road. This measure is recognized as an effective way to reduce airborne particulate matter and thereby improve air quality in the vicinity of the project site.

For the purposes of this estimation, the following project-specific parameters and assumptions have been used: the highway will be 10 km in length and 5 m in width, resulting in a total surface area of 50,000 m² that will require periodic spraying. In order to keep the road surface adequately damp and control the release of particulates, an application rate of 0.5 L/m²/day (0.0005 m³/m²/day) has been applied, in accordance with the EPA's Fugitive Dust Background Document and Technical Information Document for Best Available Control Measures (EPA-450/2-92-004). This application rate is considered appropriate under warm and dry climate conditions, such as those frequently encountered in Antalya.

Based on these parameters, the daily water consumption for dust suppression along the highway is estimated to be approximately 25 m³/day. This is a preliminary approximation and may vary depending

on site-specific conditions, operational practices, and climate factors. Water used for dust suppression will be sourced from non-potable or recycled water, where available, in order to minimize freshwater withdrawal and reduce pressure on local water resources. Dust suppression will be carried out using treated water sourced from the wastewater treatment plant outlets, water recovered from ready-mixed concrete sedimentation tanks, and, where necessary and with the appropriate permits, surface water.

Furthermore, proper application methods and equipment will be used to avoid excess usage, water runoff, or soil erosion. This practice forms a key mitigation measure to control air emissions and protect nearby communities and the environment during the construction phases of the highway project.

Concrete and Asphalt Production

Water consumption in concrete plants and mechanical equipment manufacturing plays a crucial role in ensuring production quality and efficiency. In concrete production, water is a fundamental component for the homogeneous mixing of cement and aggregates, as well as for achieving the desired strength parameters. In mechanical equipment manufacturing, water is primarily used in processes such as cleaning, cooling, and surface treatment.

Controlling and optimizing water use is essential not only for reducing operational costs but also for minimizing environmental impacts as part of effective resource management. The table below presents the estimated water consumption (m^3) for various processes in concrete plants and mechanical manufacturing workshops.

Table VII.9 Water Consumption in Concrete Plants and Mechanical Plant Manufacturing m^3

Motorway Km	Facilities Name	Area (m^2)	Maximum Hourly Capacity (m^3/h)	Operation Period (Month)	Water Consumption in Concrete Plants and Mechanical Plant Manufacturing (m^3)
55+450	Concrete Plant-1	13,946	140	36	66,667.05
59+400	Concrete Plant-2	66,450	140	36	81,020.94
	Mechanical Plant		550	16	73,601.07
	Asphalt Plant-1		240	16	-
80+400	Concrete Plant-3	15,000	140	36	56,391.94
87+700	Concrete Plant-4	42,371	140	36	42,943.78
	Mechanical Plant-2		550	16	64,216.74
	Asphalt Plant-2		240	16	-
89+700	Concrete Plant-4a	11,665	140	36	28,701.11
99+200	Concrete Plant-5	11,977	140	36	73,368.82
124+300	Concrete Plant-6	85,000	140	36	83,610.62
	Mechanical Plant-3		550	16	86,669.95
	Asphalt Plant-3		240	16	-

Excavated Materials

In the scope of road construction works, excavated materials are planned be used in the fill operations wherever the properties and the quality of the materials are suitable. According to the Project's calculations, approximately 43,842,275.13 m³ of cut material will be excavated, 4,145,614.09 m³ will be removed by stripping, and 42,291,572.24 m³ will be used in fill operations. This results in a surplus of excavated materials that cannot be used for fill. The surplus is estimated to be approximately 5,696,316.98 m³ (about 10,253,370.57 tons, assuming an average soil density of 1.8 ton/m³).

The surplus of excavated materials that is not suitable for filling operations will be stored at designated excess excavation storage areas. In this regard, list of suitable storage sites identified for the Project is presented in Table VII.5.

Potential impact of the Project due to construction materials extraction will be minimized by reusing the excavated materials as fill material to the greatest extent possible. This approach will also reduce the area required for storage of these materials. The storage areas are placed as close as possible to the Route for fuel and time efficiency. These areas may be repurposed for landscaping purposes upon the completion of the construction phase of the Project.

Construction and Demolition Wastes

Fences, barriers, buildings, walls, former engineering structures, etc. corresponding to the Motorway route will be dismantled and removed prior to construction resulting in generation of construction and demolition wastes. Those wastes will be handled with the use of appropriate construction and demolition waste areas. The generated demolition waste, mainly consisting of rubble and other construction debris, will be transported by trucks with a capacity of approximately 40 tons each. Based on the estimated waste volume per household, it is expected that about 2 truckloads will be required to remove the demolition waste generated from one residential unit.

Preliminary estimates indicate that a total of 304 houses, 37 business structures, and 831 greenhouses will be affected by the Project. Considering an average building height of 3 m for houses and business structures, with wall thickness yielding a structural volume of 300 m³ each, and a debris density of 2 ton/m³, the total waste generated from houses is estimated to be approximately 182,400 ton. The business structures are expected to produce an additional 22,200 ton of waste under the same assumptions. The greenhouses, constructed with lighter materials and typically 2 m in height, are expected to generate approximately 83,100 ton of waste, with a rubble density of 0.5 ton/m³. Overall, a total of approximately 287,700 ton of construction and demolition waste is expected to be generated by the Project. All waste will be efficiently managed, temporarily stored at designated sites, and subsequently disposed of or recycled in compliance with applicable legislation and best practices. Additionally, affected households and business owners will be permitted to salvage any materials or components of value from the demolition site following the completion of demolition activities, prior to the removal and disposal of debris.

This waste will be efficiently managed through transportation, temporary storage at designated sites, and subsequent disposal or recycling in compliance with applicable legislation and environmental best practices.

All construction and demolition wastes will be temporarily stored in designated storage areas and subsequently disposed of or recycled in compliance with applicable legislation and regulations. Proper waste management practices will be implemented to minimize potential impacts on the environment and human health.

Hazardous and Special Wastes

Hazardous waste shares the properties of a hazardous material (e.g. ignitability, corrosivity, reactivity, or toxicity), or other physical, chemical, or biological characteristics that may pose a potential risk to human health or the environment if improperly managed. Wastes may also be defined as “hazardous” by local regulations or international conventions, based on the origin of the waste and its inclusion on hazardous waste lists, or based on its characteristics (IFC, April 2007). Waste Management Regulation specifies the hazardousness properties (explosive, oxidizing, flammable, irritating, toxic, and carcinogenic, etc.) of wastes and lists the types of wastes that are to be handled directly as hazardous or after tests to be done if their hazardousness properties and concentrations are confirmed. Additionally, specific regulations are in force for the management of special wastes such as waste tires, medical wastes, waste vegetable oils, waste batteries and accumulators.

In the scope of the Project, it is likely that special wastes, hazardous wastes (e.g. spent solvents) or wastes contaminated with substances having hazardous properties (e.g. packaging wastes, personal protective equipment, oily cleaning rags, empty paint cans, chemical containers, used lubricating oil, used batteries, lighting equipment such as lamps or lamp ballasts, etc.) would be produced during the construction activities, as it is the case in many projects (IFC, April 2007).

The total quantity of hazardous waste generated on-site thought the project is estimated to be approximately 750 tons.

Amount of waste engine and machinery oils may be relatively higher in comparison to other types of hazardous and special wastes due to the large number of equipment to be involved in the construction works. Assuming that the average oil capacity of the construction machineries is 20 liters and motor oils of these machineries will be changed 4 times a year, total amount of waste oil to be produced can be estimated as given in Table VII.10.

Table VII.10. Estimated Engine Oil Waste Amounts

Machinery	Piece	Total Engine Oil Capacity (L)	Annual Engine Oil Waste (L)
Excavator	51	1,020	4,080
Grader	5	100	400
Bulldozer	14	280	1,120
Loader	20	400	1,600
Roller	10	200	800
Rock Driller	24	480	1,920
Transmixer	50	1,000	4,000
Compactor	24	480	1,920
Paver	12	240	960
Truck	147	2,940	11,760
Other (Mobile crane, injector, shotcretor, asphalt distributor, pump etc.)	115	2,,300	9,200
Total	**472**	**9,440**	**37,760**

VII.3.2. Operation Phase

The municipal solid waste will be generated by operational activities, including food waste, packaging, office waste, and hygiene-related waste. Based on an average generation rate of 1.04 kg/person/day and a site presence ratio of 0.7, total municipal solid waste from employees is estimated at approximately 182 kg/day (or 0.182 tons/day). This waste will be collected, separated where necessary, and transported to licensed disposal or recovery facilities via authorized service providers.

While the number of personnel is modest compared to the construction phase, this daily recurring load on the waste and wastewater infrastructure has been considered in this ESIA. Provided that proper mitigation measures are implemented—including adequate sanitary systems, timely collection and disposal, and compliance with national waste regulations—no significant environmental impact is anticipated during the operation phase in terms of waste and wastewater generation.

Solid waste generation during operation and maintenance activities will be caused by road resurfacing waste (e.g. removal of the old road surface material); road litter, illegally dumped waste, or generic solid waste from the toll plazas, control and weigh stations, roadside assistance/emergency and security buildings, operation/maintenance centers as wells as the employees of these facilities and users/visitors of these services, animal carcasses, vegetation waste from right-of-way maintenance, and sediment and sludge from storm water drainage system maintenance (including sediment traps and oil/water separation systems). After separate collection of recyclable wastes, all municipal solid wastes will be sent for disposal, according to the waste type, in a timely manner, to licensed facilities using licensed solid waste transportation vehicles.

During operation and maintenance activities, municipal wastewater will be generated from the toll plazas, control and weigh stations, roadside assistance/emergency and security buildings, operation/maintenance centers as well as the wastewater generated by the employees of these facilities and users/visitors of these services. It is expected that approximately 250 personnel will be employed in the Project facilities. When the estimated site availability rate is taken as 0.7 and the daily water use per person is taken as 349 liters, the total water consumption attributed to the operation personnel is calculated as approximately 61.1 tons/day. When the standard water-wastewater conversion coefficient of 0.9 is applied, the amount of domestic wastewater to be generated is estimated as approximately 55 tons/day. The facilities of the Project will be connected to the municipal sewer system or utilize septic tanks, preventing the discharge of untreated wastewater into any receiving environment.

The package wastewater treatment plant located in Concrete Plant-2, Mechanical Plant-1 and Asphalt Plant-1 Area will continue in the operation phase. In the event of a failure, emergency, overflow or maintenance, the municipal wastewater that are stored in septic tanks and/or trapped in the sewer systems will be sent for treatment, in a planned and timely manner, to licensed facilities of the relevant municipalities using licensed septic/vacuum trucks. Formal agreements for the removal and transportation of this wastewater will be finalized in advance. These agreements will clearly specify the designated disposal locations and confirm the treatment capacities of the receiving facilities.

Hazardous wastes may also be produced in limited quantities at the maintenance and operation centres. Paint waste may also be generated from road and bridge maintenance for example due to removal of old paint from road stripping and bridges prior to re-painting (IFC, April 2007). These wastes will be properly managed in line with the requirements of national waste management legislation and international good practice in order to avoid impacts on soils, nearby water resources and flora and fauna elements. Hazardous waste will be stored in separate containers in the temporary storage area allocated for this purpose, to avoid mixing with the non-hazardous waste as indicated in

Waste Management Regulation. This area will have an impermeable base/ground and will be protected from the surface flows and rain.

With proper implementation of good waste management practices, international standards and national regulations, waste generation would not cause any significant impact on the soil or water resources or on the ecosystem components that would bring associated risks on health and safety of the community and/or Project personnel. Therefore, during the operation phase of the Project, no significant impact is anticipated due to waste generation and management related to the Project facilities (including the Motorway) after implementation of necessary mitigation measures provided in the following subsection.

VII.4. Mitigation Measures

Wastes generated in the scope of Project activities will be managed in accordance with the waste management hierarchy (see Figure VII.2). In this respect, waste generation will be avoided or minimized at the source to the extent possible. Once these options are exhausted, on-site waste reuse options will be explored and implemented. If on-site waste reuse is not viable, alternative external recycling/recovery options will be evaluated. Lastly, as an ultimate alternative, wastes will be sent to final disposal only if other waste management methods are not possible. Legitimate contractors, possessing the appropriate licenses from the Ministry of Environment, Urbanization and Climate Change for the transportation, recycling/recovery or disposal of specific types of wastes, will be selected for waste management throughout all phases of the Project. Detailed procedures to be applied for each type of generated waste are provided in the Solid Waste Management Plan (presented as Annex-4). Training will be provided to the Project personnel regarding the proper implementation of waste management procedures in line with the requirements of national legislation, international standards and good practices.

Figure VII.2. Waste Management Hierarchy (https://www.epa.gov)

Waste management of all Project activities will comply with the following regulations, legislations and laws:

- Environmental Law
- Regulation on Waste Management,
- Hazardous Wastes Control Regulation,
- Water Pollution Control Regulation,
- Surface Water Quality Regulation,
- Regulation on the Control of Pollution Caused by Dangerous Substances in and around the Water Bodies,
- Regulation Concerning Protection of Groundwater against Pollution and Deterioration,
- Ordinance on Groundwater Resources,
- Regulation on Safety Data Sheet on Harmful Substances and Mixture,
- Regulation on the Preparing and Distributing Safety Data Sheets Regarding Dangerous Materials and Preparations,
- Regulation on the Classification, Labeling and Packaging of Materials and Mixtures,
- Regulation on Transportation of Hazardous Goods on Highways,
- Equator Principles (EPs) IV,
- International Finance Corporation (IFC) Performance Standards 1 and 3 and 4,
- IFC Environmental, Health, and Safety General Guidelines,
- IFC Environmental, Health and Safety Guidelines – Toll Roads,
- Regulation on the Control of Packaging Wastes,
- Regulation on the Control of Medical Wastes,
- Regulation on the Control of Waste Oils,
- Regulation on the Control of Waste Batteries and Accumulators,
- Regulation on the Control of Waste Tires,
- Regulation on the Control of Waste Vegetable Oils,
- Regulation on the Control of Excavation Soil, Construction and Demolition Wastes,
- Regulation on Mining Wastes,
- Regulation on the Landfill of Wastes,
- Circular on the Preparation of Implementation Project for Landfills,
- Circular on Landfill of Mining Wastes and Technical Arrangement of Other Landfills,
- Mining Law,
- Forestry Law,
- Pasture Law,
- Pasture Regulation,
- Regulation Concerning the Rehabilitation of the Lands Disturbed by Mining Activities,
- World Business Council for Sustainable Development (WBCSD), December 2011, and
- Guidelines on Quarry Rehabilitation.

Regarding the management of Project-sourced wastes, written agreements/protocols will be established with the local waste management service providers that have valid permits and licenses from the Ministry of Environment, Urbanization and Climate Change. Copies of all the relevant documents will be retained at the campsites and in Project offices.

VII.4.1. Land Preparation and Construction Phase

Hazardous and special wastes such as waste oils, tires, will be generated from maintenance of vehicles and equipment during the construction phase. These wastes will be properly managed in line with the requirements of national waste management legislation and international good practice in order to avoid impacts on soils, nearby water resources and flora and fauna elements. Hazardous waste will be stored in separate containers in the temporary storage area allocated for this purpose, to avoid mixing with the non-hazardous waste as indicated in Waste Management Regulation. This area will have an impermeable base/ground and will be protected from the surface flows and rain. General measures that will be applied to avoid or minimize potential impacts or risks sourced from waste generation are summarized below (provided in ESMP, Annex-6):

- Wastes will be collected systematically in closed containers with various types of wastes (non-hazardous, hazardous and special wastes) sorted for proper handling and disposal.
- Throughout the project life cycle, hazardous materials will be stored in designated areas at storage points with appropriate containment and Material Safety Data Sheets (SDS). When chemicals need to be temporarily removed from these designated storage areas for operational purposes, appropriate spill control materials will be available at the points of use.
- Recyclable wastes will be collected separately to be transported by licensed recycling/recovery facilities.
- The use of non-hazardous materials will be preferred, whenever possible and feasible. If the use of hazardous materials is unavoidable, the generated hazardous wastes will be segregated from non-hazardous wastes to prevent mixing and contamination. Therefore minimizing the amount of hazardous waste by preventing new formations.
- No waste will be burned, illegally dumped or buried on site.
- To prevent solid wastes from being blown away by the wind, wastes will be stored in closed containers and disposed of in a timely manner. Any garbage scattered due to wind, rain etc. will be cleaned daily. The cleanliness of the construction site areas, campsites and their surroundings will be maintained properly.
- Project personnel will be trained on proper waste management procedures.
- Temporary storage areas will be established at the campsites for the storage of both hazardous and non-hazardous wastes. The necessary permits will be obtained for these areas and then they will be put into use.
- Licensed waste transportation vehicles will be used to remove wastes temporarily stored at Project sites. Private companies and relevant municipalities will be consulted for this purpose. Potential management options will be evaluated in accordance with the relevant waste management regulations, and all actions will be documented and retained by Project Management.

Temporary hazardous and non-hazardous waste storage areas will have the following features (also provided in detail in ESMP, Annex-6):

- All chemicals and hazardous materials will be stored in designated hazardous materials storage areas that has lean-to roof, concrete floor, secondary containment of at least 110% of the stored volume and proper drainage for spills/leaks;
- The roof and sides of the storage area will be properly covered to prevent rainwater intrusion;

- The floor of the area will be sealed with either reinforced concrete or epoxy material;
- Drainage of the areas will be facilitated with the channels leading to blind sumps;
- Access to storage areas will be controlled through gates equipped with proper locking systems;
- Necessary signs and boards will be properly placed; name and contact number of the personnel responsible for the area will be displayed on the boards;
- Separate storage compartments/containers will be provided for the storage of different types of wastes;
- Leak-proof containment structures will be placed under the tanks/drums holding liquid wastes to prevent contamination from any potential spillage/leakage;
- For the storage of liquid wastes greater than 220 liters, secondary containment will be provided with an available volume of at least 110% of the largest storage container or 25% of the total storage capacity, whichever is greater;
- Relevant fire-fighting equipment (i.e. mobile fire extinguishers) will be kept readily outside the storage areas;
- Absorbents will be readily available to respond to potential leakage/spillage events;
- Adequate ventilation will be provided in areas designated for storage of volatile wastes.
- All the hazardous and non-hazardous temporary waste storage areas will be subject to regular visual inspections by assigned site personnel. Additional information is presented in ESMP, Annex-6.

Municipal Wastes/Wastewater

Municipal solid wastes to be generated at campsites and other work sites will be stored in closed containers and will be collected by municipality trucks or licensed firms for disposal. Separate waste containers (drums, bins, or bags) will be provided for different types of waste. As mentioned previously, closest landfills will be considered for the disposal of Project-sourced municipal solid wastes. Project Sponsor will coordinate with the relevant municipalities to ensure that municipal solid wastes are disposed of in accordance with the established agreements.

Municipal wastewater generated at the campsites and work sites will be treated by package WWTPs (wastewater treatment plants). Environmental permits for discharges from these package WWTPs will be obtained, and wastewater disposal agreements/channel connection permits will be established with the relevant municipalities. The quality of the treated water will meet the Project Standards.

Additionally, the capacity of package WWTPs will be monitored to ensure operational standards. The monitoring will be conducted in compliance with national legislation and international standards.

A detailed monitoring program will be developed for all discharges from WWTPs, including those in the temporary construction area. The program will specify discharge locations, monitoring frequencies, and applicable discharge standards. In addition, the operational capacity of package WWTPs will be regularly monitored to ensure continued compliance with national legislation and applicable international standards. A comprehensive maintenance program will also be developed and implemented to ensure the effective and uninterrupted functioning of all WWTP units.

Furthermore, a clear process will be established for investigating any non-compliance with discharge limits, including corrective measures and temporary storage of effluent until regulatory compliance is restored.

The accredited laboratories (accredited by TÜRKAK or a similar national accreditation body) will perform a range of physico-chemical and microbiological tests, including pH, suspended solids, BOD, COD, and heavy metals, following standard analytical methods (EPA, ISO). Wastewater management practices at concrete plants will also be monitored. Additionally, presence and functionality of drainage systems will be evaluated annually during the operation phase. Further details of these processes provided in ESMP, Annex-4.

Excavated Materials

Materials to be excavated from the Motorway route will be reused as fill material in the construction of the road base, shoulders, side slopes etc. to the extent the quality and quantity of materials allow. This approach will minimize excavation waste and reduce the volume of excess material that needs to be permanently stored. The excess of excavated materials and/or the materials are not suitable for being used in construction or filling processes, will be permanently stored in the designated storage areas. Permits of these designated storage areas will be acquired from the related authorities. Transportation of the materials to the storage areas will be carried out with licensed vehicles. Locations of planned designated storage areas for the excess excavated materials are given in previous chapters/sections.

Construction Wastes

Construction and demolition wastes will be disposed of in accordance with the Regulation on the Control of Excavation Soil, Construction and Demolition Wastes. Generated scrap metals will be collected separately from other construction wastes. These wastes will be managed by the recycling/recovery companies licensed by Ministry of Environment, Urbanization and Climate Change.

Hazardous and Special Wastes

Hazardous and special wastes (e.g., waste oils, waste tires, waste batteries, and waste accumulators) will be collected separately in closed containers and will be transported to licensed firms for recycling, recovery, or final disposal facilities. Hazardous materials will not be stored on bare soil to prevent contamination. Supervision will be implemented during the handling of all dangerous materials. Impervious bunds, impermeable floors, secondary containments, and other containment techniques will be employed where hazardous materials are handled. All processes/works that includes hazardous materials will be conducted in accordance with the Hazardous Wastes Control Regulation.

Waste Oil

Waste oils will be stored separately in tanks, containers, or similar structures placed at temporary waste storage sites on impermeable surfaces. Waste oils generated at the facilities will be analyzed at the competent laboratories and will be classified according to their categories. Waste oils temporarily stored at the Project facilities will be collected and transported to licensed recovery facilities by licensed transfer vehicles in accordance with the Regulation on the Control of Waste Oils.

Medical Waste

Medical waste generated at the construction site infirmaries will be stored separately from other wastes types. Special storage bags and boxes will be used for this purpose. Medical waste will be

temporarily stored in sealed, labeled containers within a secured area of the infirmary facility until sent for disposal in accordance with Medical Waste Control Regulation. Unauthorized access to the areas where medical wastes are temporary stored will be prevented. Until final disposal, un-sharp wastes will be stored in specially designed red bags, marked with “International Bio-Hazards” symbols and labeled “Warning: Medical Waste” on both sides. Sharp medical wastes will be stored separately in containers designed to be puncture-resistant, tear-resistant, leak-proof, and tamper-proof, with visible labeling indicating “International Bio-Hazards” and “Warning: Sharp Medical Waste”. Temporary stored medical wastes will be transported using appropriate and licensed medical waste transport vehicles, in compliance with the Regulation on the Control of Medical Wastes.

Waste Batteries and Accumulators

Generated waste batteries and accumulators will be stored separately from other waste types Temporary stored battery and accumulator wastes will be transported by licensed vehicles, in accordance with Regulation on the Control of Waste Batteries and Accumulators.

Treatment Sludge

Generated treatment sludge at the package WWTPs will be analyzed in accordance with the National Waste Management Regulation in order to identify its characteristics (hazardous or non-hazardous). Depending on its characteristics, waste treatment sludge will be disposed of at a licensed waste disposal site by companies licensed from the Turkish Ministry of Environment, Urbanization and Climate Change.

All expected waste types to be generated are provided in Table VII.11, including their waste codes and descriptions. Required agreements will be established for the management of all potentially generated wastes.

Table VII.11. Wastes to be collected by the Contractor

Waste Code	Code Description
20 01 40	Metals (Scrap)
17 04 05	
15 01 10	Steel Barrel
	Tin
	Plastic
15 02 02	Cloth, Glove Filter Materials
16 01 07	Oil Filters
16 06 01	Accumulator
15 01 11	Pressure Vessels
20 01 21	Fluorescent and Mercury Containing Wastes
13 01 13	Hydraulic Oil
20 01 26	Vegetable Waste Oil
08 01 11	Waste Paint Varnish

Waste Code	Code Description
08 03 17	Cartridge - Toner
16 02 15	Discard Electronic Equipment
17 04 09	Contaminated Metal
16 05 06	Laboratory Chemicals
10 13 14	Concrete Mud

VII.4.2. Operation Phase

During the operation phase, measures proposed for the management of construction phase wastes will continue to be applied where applicable. Additional waste management measures to avoid/minimize waste production and manage unavoidable wastes during the operation phase are provided below:

- Chlorine free solvents and lead-free paints will be used within the scope of maintenance activities.
- Any waste identified or generated in the Motorway corridor as a result of the site cleanings, sediment removal, tree/shrub trimming, animal death and spill/scattering of waste tires, metal pieces, etc. will be immediately removed from the road surface and disposed of in accordance with the relevant national regulations within 7 days;
- Road resurfacing wastes will be prioritized for recycling wherever feasible, by using them as aggregate or base material for the pavement;
- Recyclable materials such as glass, scrap tires, certain types of slags and ashes will be added to the new asphalt and concrete mixes;
- Unused or partially consumed products (e.g. paint, herbicide) requiring disposal will be minimized through effective inventory management;
- Any obsolete product will be removed/managed in accordance with the national regulations, and international standards;
- The characteristics (hazardous or non-hazardous) of the sediments and sludge resulting from drainage system maintenance will be determined in accordance with the Waste Management Regulation. Disposal methods appropriate to the identified characteristics will then be applied;
- Vegetation waste will be composted for reuse as landscaping fertilizer where possible.

VII.5. Summary of Assessments and Residual Impacts

Table VII.12 provides a summary of this chapter. With proper implementation of good waste management practices, international standards and national regulations, use of resources and waste generation related to the Project would not cause any significant impact on the soil or water resources or on the ecosystem components that would bring associated risks to the health and safety of the community and/or Project personnel. Therefore, during both land preparation and construction, and operation phases of the Project, no significant impact is anticipated due to waste generation and management related to the Project facilities (including the Motorway) after implementation of necessary mitigation measures provided in this chapter.

Table VII.12. Summary of the Assessments Waste Management

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Land Preparation and Construction Phase												
Incremental load on the capacities of the local waste management facilities due to Project-sourced municipal solid wastes.	Local solid waste infrastructure	Adverse	Local	Medium	Negligible	Long-term reversible	Continous	Restricted (C)	Low (1)	Low(C1)	• Cooperation will be established with licensed local service providers (e.g. municipal and/or private licensed waste transportation/recycling/ recovery firms) through written agreements/protocols to ensure regular and planned management/disposal of Project-sourced wastes. • The amount of wastes sent to off-site management will be minimized by implementation of the Solid Waste Management Procedure which incorporates and relies on the waste managament hierarchy. • Wastes will be collected systematically in closed containers and various types of wastes (non-hazardous, hazardous and special wastes) will be sorted for proper handling and disposal. • Recyclable wastes will be collected separately and sent to licensed recycling facilities. • The use of non-hazardous materials will be preferred whenever possible and feasible. If the use of hazardous materials is inavoidable, generated hazardous wastes will be segregated from non-hazardous wastes. Therefore, minimizing the amount of hazardous waste by preventing new formations. • No waste will be burned, illegally dumped or buried on site. • To prevent solid wastes from being blown away by the wind, wastes will be stored in closed containers and disposed of in a timely manner. Any garbage scattered due to wind, rain etc. will be cleaned daily. The cleanliness of the construction site areas, campsites and their surroundings will be maintained properly. • The Project personnel will be trained on proper waste management procedures. • Temporary storage areas will be established at the campsites for the storage of both hazardous and non-hazardous wastes. • Licensed waste transportation vehicles will be used to remove wastes temporarily stored at Project sites. Private companies and relevant municipalities will be consulted for this purpose. Potential management options will be evaluated in accordance with the relevant waste management regulations, and all actions will be documented and retained by Project Management. • All chemicals and hazardous materials will be stored in designated hazardous materials storage areas that have lean-to roof, concrete floor, secondary containment of at least 110% of the stored volume and proper drainage for spills/leaks. • The roof and sides of the storage area of chemicals and hazardous materials will be properly covered to prevent rainwater intrusion and the floor of the area will be sealed with either reinforced concrete or epoxy material to prevent contamination. In addition, drainage of the areas will be facilitated with the channels leading to blind sumps. • Access to storage areas of chemicals and hazardous materials will be controlled through gates equipped with proper locking systems. Necessary signs and boards will be properly placed; name and contact number of the personnel responsible from the area will be put on the boards. • Separate storage compartments will be provided for the storage of different types of chemicals and hazardous wastes. Leak-proof containment structures will be placed under the tanks/drums holding liquid wastes to prevent contamination from any potential spillage/leakage. • For the storage of liquid wastes greater than 220 liters, secondary containment will be provided with an available volume of at least 110% of the largest storage container or 25% of the total storage capacity,	Negiligible

											whichever is greater. Absorbents will be readily available to respond to potential leakage/spillage events. • Relevant fire-fighting equipment (i.e. mobile fire extinguishers) will be kept readily outside the storage areas of liquid chemicals and hazardous materials. Adequate ventilation will be provided in areas designated for storage of volatile hazardous and chemical wastes. • All the hazardous and non-hazardous temporary waste storage areas will be subject to regular visual inspections by assigned site personnel.

VIII. WATER RESOURCES

This Chapter identifies the existing water resources' characteristics (physical, biological, and chemical) and usage along the Motorway route and assesses the potential impacts of the Project on these aspects. Measures proposed to mitigate the potential impacts, and the residual impacts are also described in this Chapter.

VIII.1. Assessment Methodology and Data Sources

To assess the impacts to the water resources and possible water usage by the Project Sponsor, the main water resources in the area have been determined and evaluated by considering the physical and chemical characteristics of the resources. The data concerning the dam lakes near the project area has been obtained from State Hydraulic Works (DSI) database, Antalya Provincial Environmental Status Report prepared in 2023, and internet resources.

Sampling points for both surface water and groundwater resources have been carefully selected to represent areas where potential environmental impacts may occur. In addition to considering possible future water use, the selection of groundwater sampling locations also takes into account the distribution of different hydrogeological units. This approach helps to better characterize the spatial variability of groundwater quality in relation to the underlying geological formations. All water quality analyses have been carried out in accordance with relevant Turkish regulations, which are harmonized with EU standards. The results of this sampling and analysis campaign will serve as baseline data for both surface and groundwater resources, providing a scientific foundation for impact assessment studies.

Significance Criteria

The significance criteria for the impacts on water resources have been determined as high, medium, or low, based on the evaluation of the magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter 4 ("ESIA Methodology") are used to determine the magnitude of impact on the water resources. The sensitivity/value criteria to be used in the scope of impact assessment for the resources are based on the existing and potential use of the resource, existing quality, and expert judgment.

VIII.2. Baseline Conditions

The Motorway route crosses many surface water resources, including intermittent and perennial rivers and creeks. These resources may be affected by the Project activities in various ways during the construction and operation phases of the Project if not properly mitigated.

In general, the highway route passes through the Antalya River basin; it has river crossings with high flow rates, such as Köprüçay and Manavgat Stream. Hence, viaducts were included in the Motorway design.

An intensive baseline water quality sampling and analyses program (covering both surface and groundwater resources) has been conducted to characterize the baseline water quality conditions at such areas and other surface water bodies crossed by the Project. The program included in-situ measurements, sampling, and laboratory analyses. The interpretation of measurement results is done

in accordance with relevant national and international standards, and baseline conditions regarding surface and groundwater resources are provided in this Chapter.

VIII.2.1. Antalya Basin

The Antalya basin is surrounded by Sultan Mountains in the north, Alanya District and Toros Mountains in the east, Beydağları and Katrancık Mountains in the west, and is bordered by Antalya Bay in the south. There are Doğu Akdeniz and Konya Kapalı Basins to the east, the Batı Akdeniz and Burdur Basin to the west, and the Akarçay Closed Basin to the north in the region (see Figure VIII.1). The narrowest point in the east-west direction of the basin, which is approximately 200 km long and 170 km wide, is within the Eğirdir district of Isparta province and its width is approximately 30 km. Basin area is approximately 32,041 km^2 and covers approximately 4% of Türkiye's surface area. According to the population and area information in the Antalya Basin, the general population density is 109 people/km^2 and this value is above the 97 people/km^2 value determined by Turkstat for Türkiye *(TUBITAK MAM, 2013 & MoAF Web Site*).

Antalya Basin is located in the Mediterranean Region (south) of Türkiye, between the Western Mediterranean and Eastern Mediterranean, and covers the area where rivers Boğaçay, Düden Stream, Köprüçay, Aksu Stream, Karpuz, Alara, Kargı, Oba and Dim Streams flow into the Mediterranean Sea. In the upper part of the basin, there are mainly Pupa Stream, Hoyran Stream, Yalvaç Stream and Korkuteli Stream.

The main point and diffuse pollutant sources that create pressure in the Antalya Basin are generally untreated wastewater from urban sources, discharge waters from industries (discharge waters from rural septic tanks operating on the untreated wastewater of Isparta Stream (leatherworks, marble enterprises), leachate from irregular solid waste landfills, fertilizers and pesticides used in agricultural activities mixing with surface and groundwater, and pollution from livestock activities mixing with groundwater. In addition, tourism activities and climate change are also pressure factors affecting the Antalya basin.

In basin management studies, a sub-basin based management approach was adopted by considering the pressure factors in the basin. For this purpose, sub-basin delimitations were made by taking into consideration the hydromorphological and topographical status of the basin; similarities and differences of pressure factors; studies carried out by institutions and administrative status.

Antalya Basin Conservation Action Plan studies were divided into 5 sub-basins in accordance with the above principles. These sub-basins are;

- Dim Stream Sub-basin
- Düden Stream Sub-basin
- Manavgat Stream Sub-basin
- Köprüçay Sub-basin
- Aksu Stream Sub-basin.

The route passes through the Manavgat, Aksu and Dim stream sub-basins. Sub-basins map of Antalya Province is given in Figure VIII.2.

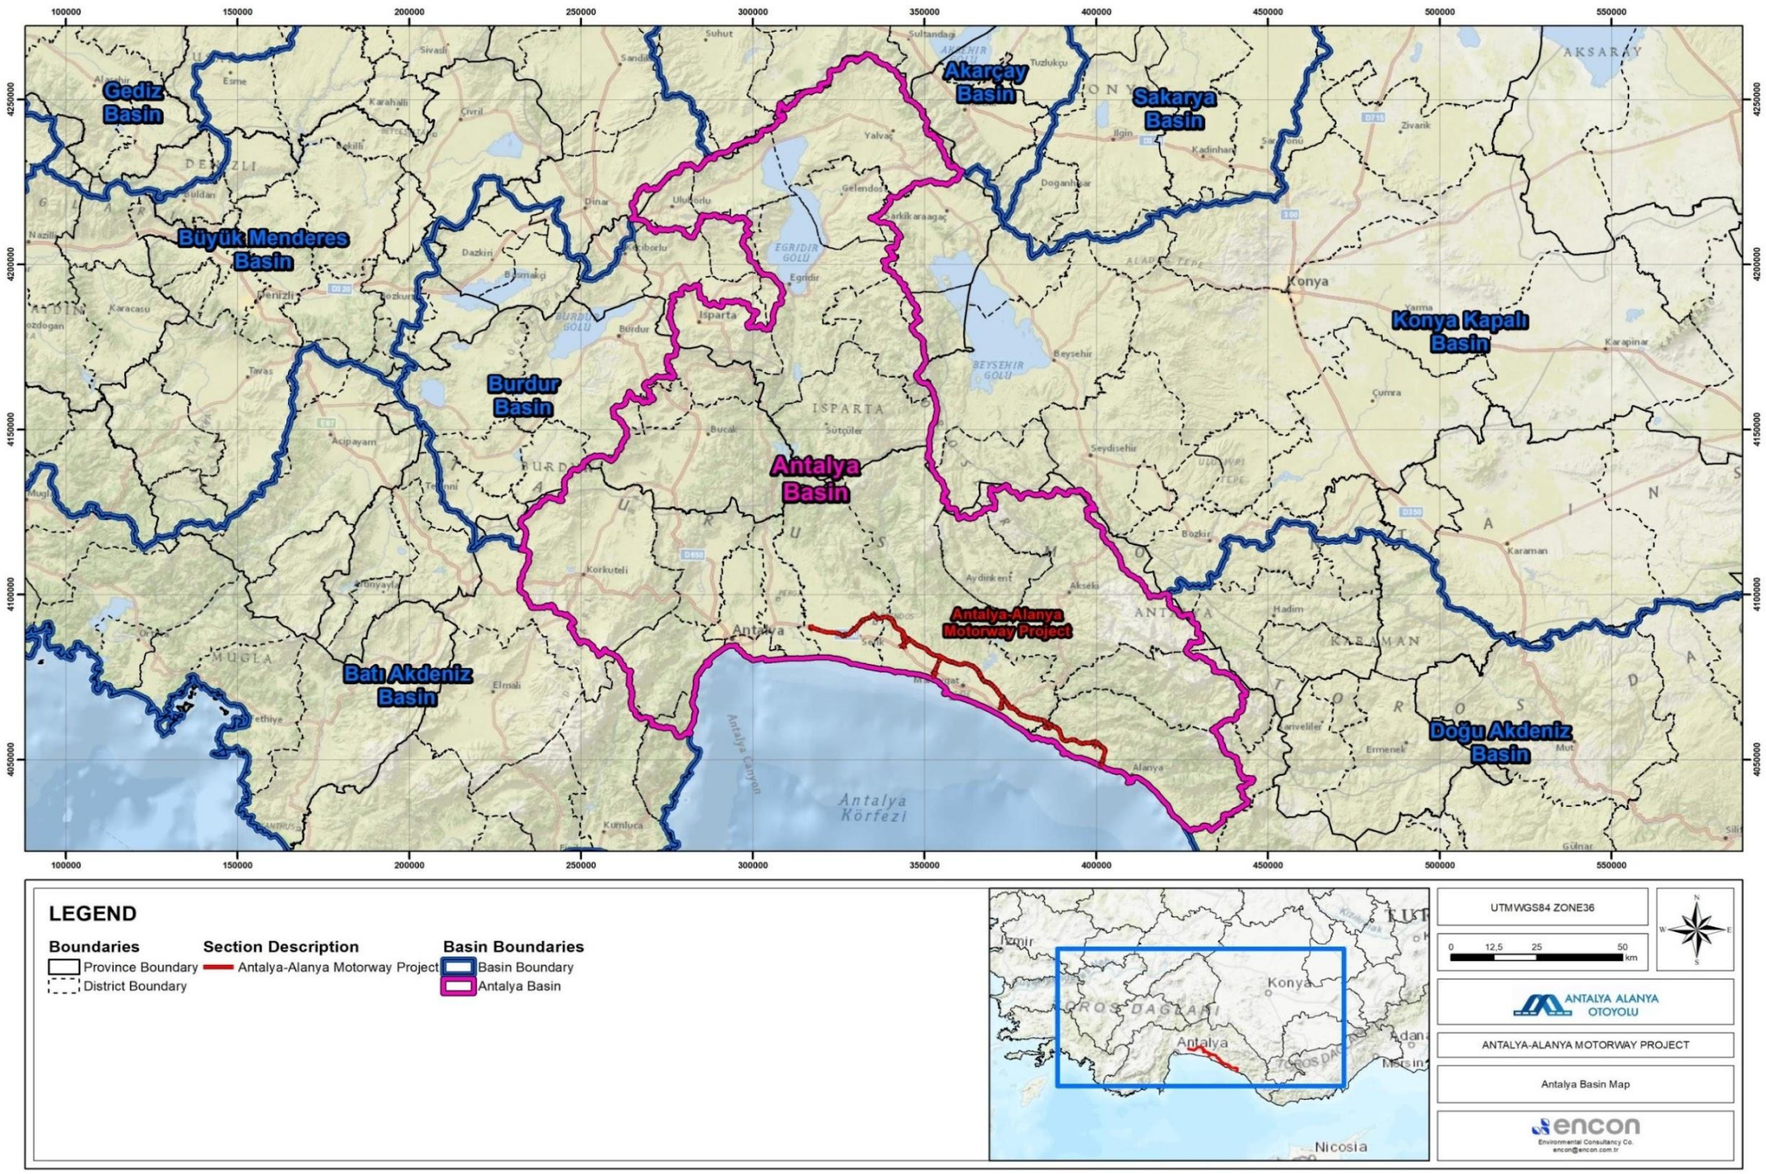

Figure VIII.1 Antalya Basin Map

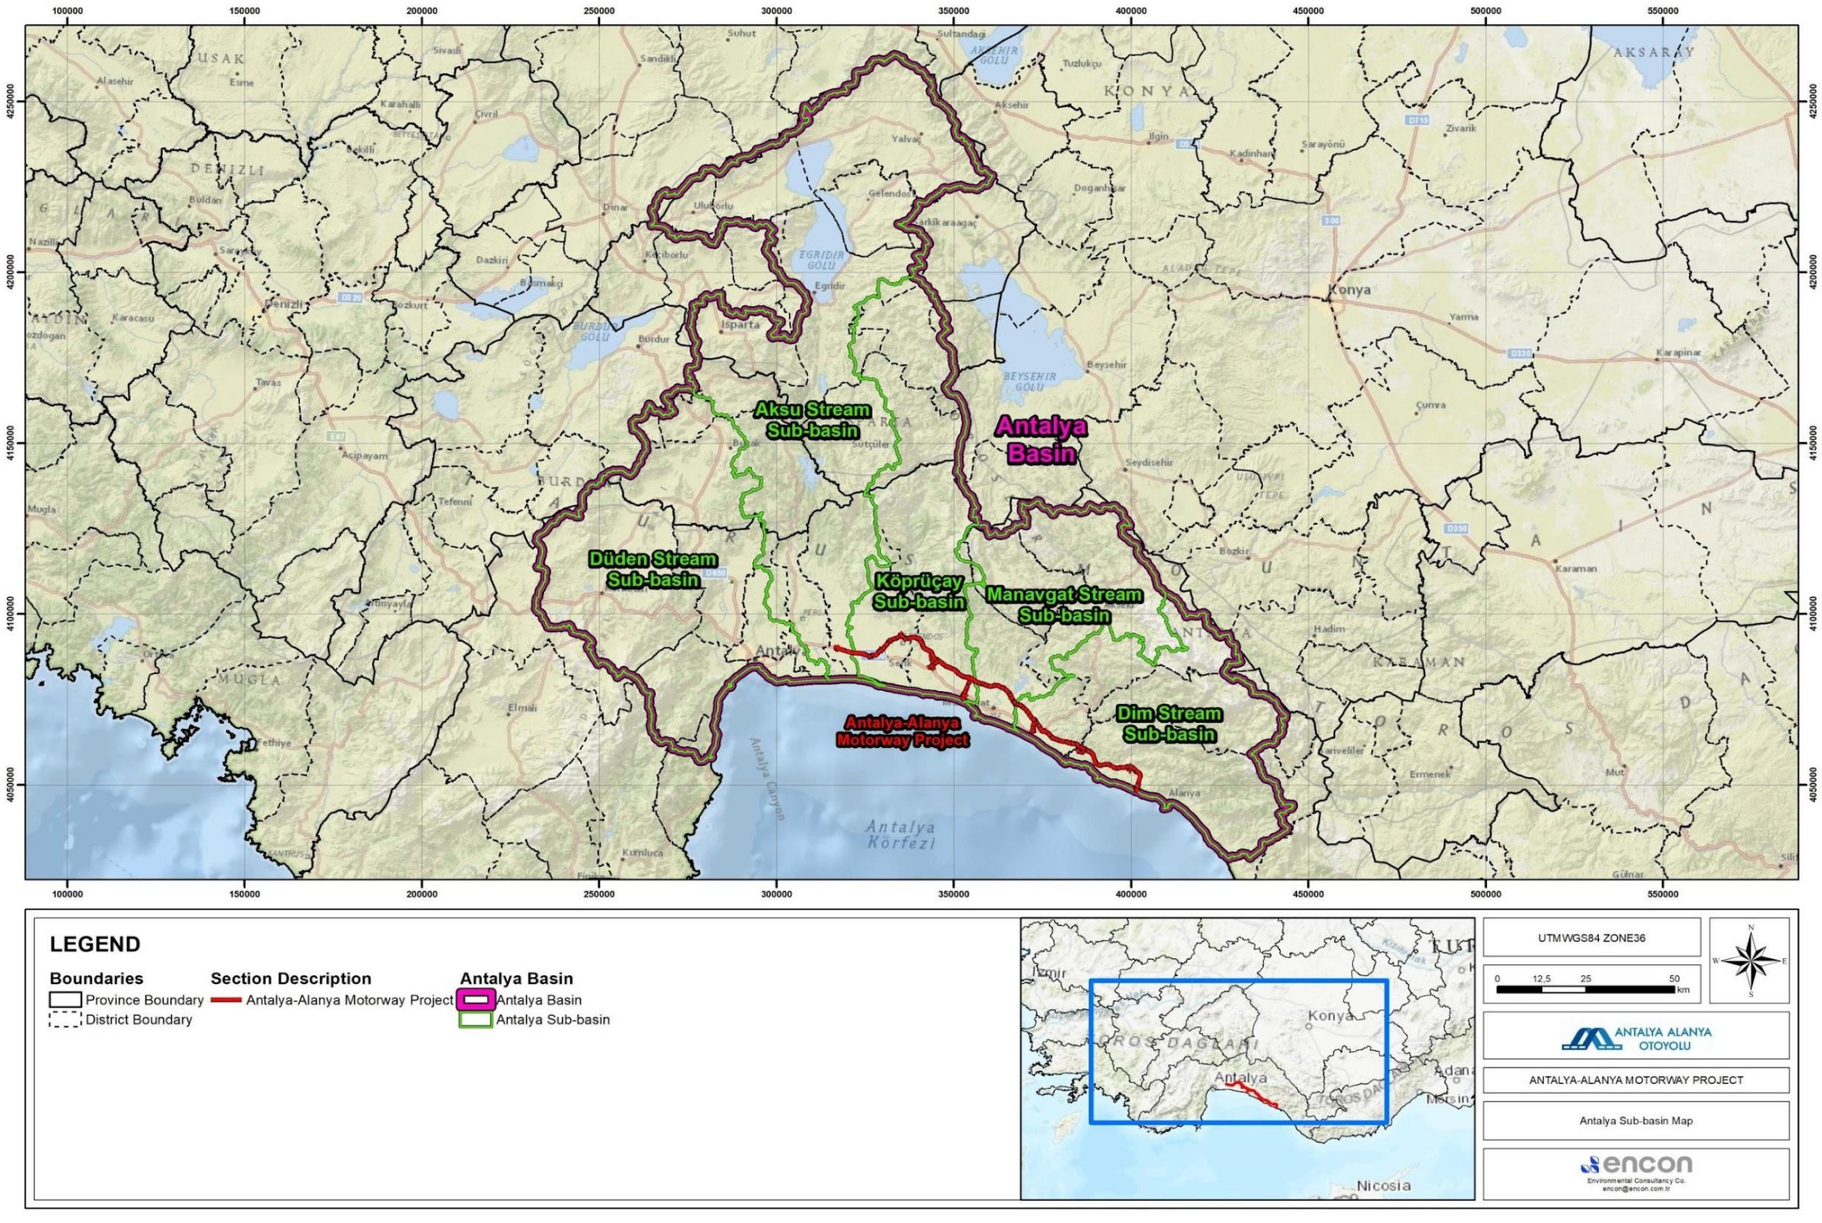

Figure VIII.2 Antalya Sub-basins Map

VIII.2.2.Water Resources

Antalya Basin is one of the richest regions of Türkiye in terms of water resources with 12,283.44 hm^3 of usable water potential. In order to identify and determine the surface water bodies in the Antalya Basin, a detailed assessment has been made. A total of 155 surface water bodies (109 rivers, 32 lakes, 11 transitional water bodies and 3 coastal water bodies) were identified[1].

VIII.2.2.1. Standing Water Bodies

Information on the dams in the Antalya Basin is presented in Table VIII.1 for each sub-basin and the drinking water.

Table VIII.1. Information on Dam Lakes in the Basin

No.	Dam Lake	Province	Surface Water	Area (ha)	Purpose
1	Karacaören -1 Dam Lake	Burdur	Aksu Stream	4,550	Irrigation, Energy, Flood
2	Karacaören 2 Dam Lake	Burdur	Aksu Stream	234	Irrigation, Energy, Flood
3	Sücüllü Dam Lake	Isparta	Sücüllü Stream	82	Irrigation
4	Uluborlu Dam Lake	Isparta	Pupa Stream	125	Irrigation
5	Alanya Dim Dam Lake	Antalya	Dim Stream	470	Irrigation, Energy, Drinking
6	Kokuteli Dam Lake	Antalya	Korkuteli Stream	220	Irrigation, Flood, Drinking
7	Onaç-2 Dam Lake	Burdur	Onaç Stream	356	Irrigation,
8	Oymapınar Dam Lake	Antalya	Manavgat Stream	470	Energy
9	Manavgat Barajı	Antalya	Manavgat Stream	860	Energy
10	Sorgun Dam Lake	Isparta	Sorgun Stream	122	Irrigation

The dams under construction in the basin and their construction start years are listed below (State Hydraulic Works Website).

- Manavgat Çardak Toksurlar Dam (2013),
- Serik Kırkgeçit Dam (2013),
- Küçük Aksu Dam (2013),
- Manavgat Yeşilbag Dam (2013),
- Alanya Yeniköy Dam (2015),
- Manavgat Çardak Dam (2018).

In addition to these dams in the Antalya Basin, the repair of the Manavgat Naras dam, which was commissioned for irrigation and flood services in 2014, will be started. (State Hydraulic Works Official Website)

[1] *MoEUCC, April 2024, River Basin Management Plan Strategic Environmental Assessment Scoping Report*

The construction of Manavgat Çaltepe Saçıdere pond, which was started to be constructed in 2013, continues. In addition, Manavgat Taşağıl Karabekir Dam, which was built for irrigation purposes and started operation in 2010, and Serik Akbaş Dam, which was built for irrigation and flooding and started operation in 2016, are the other dams in the basin[2].

Alanya Dim Dam Lake

The dam lake/reservoir is approximately 21.0 km east of the motorway route (see Figure VIII.3). The dam was constructed between 1977-1984 period for irrigation, energy and drinking purposes. The dam's height is about 135 m from the river bed, while reservoir water volume is 250,000,000 m^3 and reservoir surface area is 4.7 km^2 on normal water level.

Oymapınar Dam Lake

The dam lake/reservoir is approximately 8.8 km north of the motorway route (see Figure VIII.3). The dam was constructed between 1977-1984 period for energy purposes. The dam's height is about 185 m from the river bed, while reservoir water volume is 300,000,000 m^3 and reservoir surface area is 4.7 km^2 on normal water level.

Manavgat Dam Lake

The dam lake/reservoir is approximately 2.0 km north of the motorway route (see Figure VIII.3). The dam was constructed between 1986-1987 period for flood control and irrigation purposes. The dam's height is about 29 m from the river bed, while reservoir water volume is 88,980,000 m^3.

Manavgat Naras Dam Lake

The dam lake/reservoir is approximately 3.5 km north of the motorway route (see Figure VIII.3). In operation since 2014, the dam's height is about 116 m from the river bed while the reservoir water volume is 106,550,000 m^3.

As presented, there is one water resource used for drinking purposes within the project area (Alanya Dim Dam). The Regulation on the Protection of Drinking and Utility Water Basins describes the horizontal terrestrial area with a width of 300 m starting from the line between the maximum water level and land for artificial or natural lakes. The regulation has stringent provisions regarding this protection status restrictions can be summarized as follows:

- No activities causing water pollution are allowed within the area,
- These areas are only open for public use; no private operations shall be established,
- Disposal, transfer, or storage of solid wastes or treated/untreated wastewaters,
- Quarries,
- Fuel storage,

[2] *2023-2027 Strategy and Action Plan for Combating Agricultural Drought in Antalya Province; Antalya Provincial Directorate of Agriculture and Forestry*

- Agricultural activities,
- Urbanization/touristic facilities/industrial activities,
- Livestock breeding activities are not permitted within the area.

VIII.2.2.2. Running Water Bodies

There are 3 important rivers intersecting with the route in the Antalya basin. One of them is the 178 km long Köprüçay. Köprüçay carries 2840 hm³ of water per year. The river is fed by a total of 180 karst springs. Therefore, it continues to flow even in dry summers. The flow rate of the river increases with the increase in precipitation in winter and melting of snow in spring. Ayvalı stream and Karacahisar streams originating from Anamas (Güllüce) Mountain in the south-east of Lake Eğirdir merge to form Köprüçayı. It also receives Kocadere and Sağırini streams in its lower parts. First, the water flowing in the wide valley enters the narrow canyon in Bolhasan village. It meanders through the Serik plain and flows into the Mediterranean Sea. The canyon valley stretching between Bolasan village and Beşkonak town has been declared as Köprülü Canyon National Park. In the area where picnics and camping can be organized, fishing is also practiced. Köprülü Canyon has a length of 14 km and a side height of 100 m. It is one of the most important rafting areas in Türkiye.

Another important river crossing the route is the 93 km long Manavgat River with a flowrate of 4,020 hm³ of water per year. It is formed by the merger of the tributaries born between the Western Taurus mountain ranges. Heading south-west, it passes through narrow and steep-sided canyons and forms the Manavgat Waterfall. It flows into the sea from an alluvial coastal plain east of Manavgat district center. It is the river with the most regular flow regime in Türkiye and has Oymapınar and Manavgat dams on it. As a river of the Mediterranean climate with dry and hot summers, it passes 30-65 m³ of water per second on average from July to the end of October. During normal swells, 150-200 m³ of water per second passes through its bed.

Alara, also known as Ulugüney Stream, is 82 km long and its flow rate is 31.2 m^3/sec. The stream takes its source from Kuşak Mountain and Akdağ at an altitude of 2647 km. It is formed by the combination of Oğuz, Çakalsakmak, Alıkpazı and Yukarıbük streams in the southeast of Gündoğmuş district. The Alara Stream valley serves as a gateway connecting the western part of Alanya to the interior. There is Karpuz Stream in the west and Kargı Stream basin in the east. The stream, which generally flows in the east-west direction, flows north-south south of Güneycik and reaches the sea at the borders of Boztepe, Manavgat village.

The road route also intersects with Karpuz Stream. The stream, which has a lower flow rate (4.2 m^3/sec) and a length of 36 km compared to the other three streams, takes its source from 2,544 m high in the Toros Mountains. It receives Uludere between the villages of Cendeve and Geriş and a few streams near Murtiçi. It flows in the canyon valley between Kızılkaya neighborhood and Gürleğen Mountain and into the sea between Uzunlar, Manavgat and Taşkesiği, Manavgat, east of Manavgat.

Kargı Stream Valley is a deep valley located about 12 kilometres north of Alanya. The stream originating from Akdağ is approximately 45 km long and flows in the east-west direction. It flows into the Mediterranean Sea at Çiftliği. The river is used for agricultural irrigation.

Pressure factors and their impacts on resources have been identified for the rivers in the Antalya basin (*Basin Protection Action Plans; TUBITAK MAM*). The pressures and impacts of the rivers in the route impact area are presented in Table VIII.2. The hydrology map with water crossings along the project route is shown in Figure VIII.4

Table VIII.2 Pressures and Impacts on Rivers/Streams on the Route

River name (if available)	Pressure Factor	Pressure Type
Köprüçay Stream	Domestic Wastewater Discharges Tourism Facilities Fish Farms	Point, Diffused
Manavgat River	Domestic Wastewater Discharges Agriculture Activities	Point, Diffused
Alara (Ulugüney) Stream	Pollutants from agricultural activities Water use for agricultural purposes	Diffused
Karpuz Stream	Sand and gravel purchase	Diffused

(Basin Protection Action Plans; TUBITAK MAM)

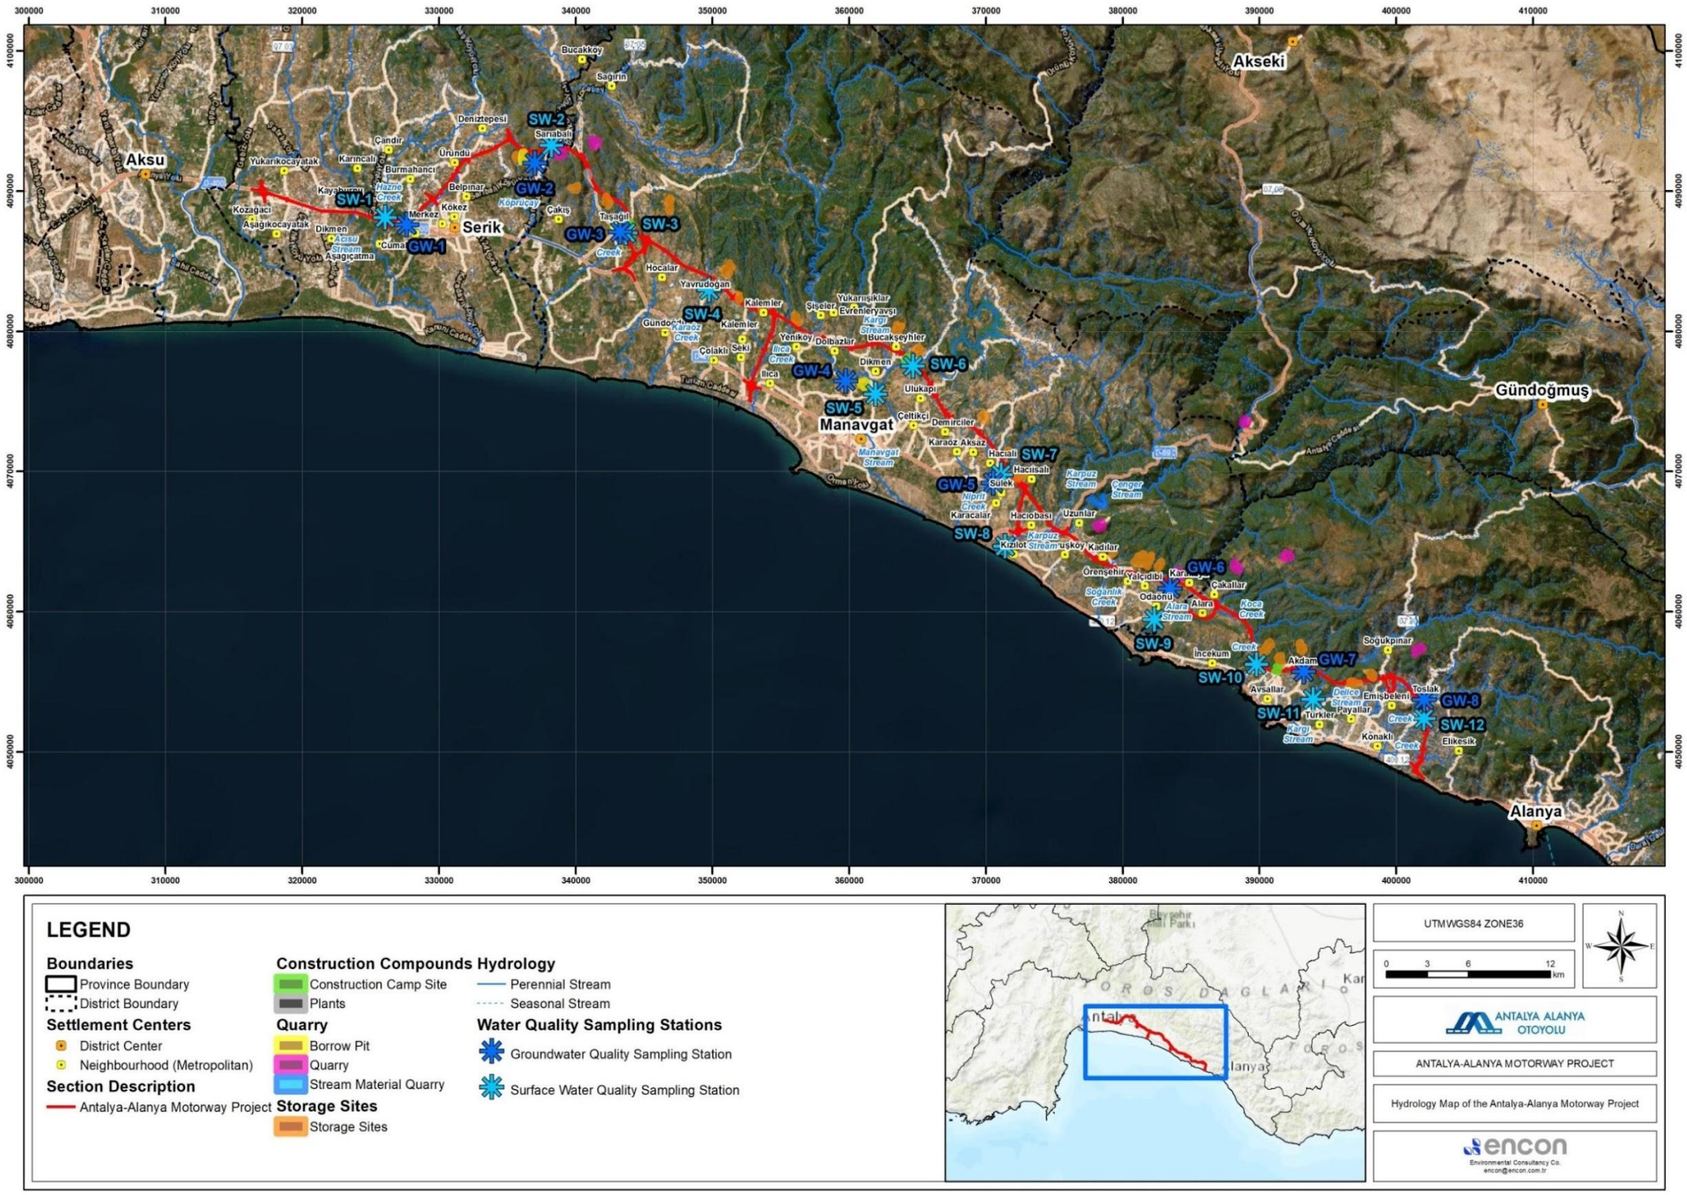

Figure VIII.4 Hydrology Map

Floods

Antalya Basin Flood Risk Management Plan, prepared in 2016 by the now-defunct General Directorate of Water Management under the former Ministry of Agriculture and Forestry, aimed to establish a structure focused on assessing and managing flood risks, and to reduce the adverse effects of floods on human health, the environment, cultural heritage, and economic activities.

Through this plan, it has been made possible to enhance Türkiye's administrative and technical capacity to a more advanced level in order to mitigate the negative consequences of floods; to ensure better coordination among various groups such as local authorities, industrial stakeholders, farmers, the tourism and construction sectors; and to raise awareness among the general public.

The province of Antalya is located within the Antalya Basin, one of the richest regions in Türkiye in terms of water resources.

Within the scope of the Antalya Basin Flood Risk Management Plan, the practices related to the assessment and management of flood risks in the basin were carried out by considering best practices. Accordingly, studies were conducted based on three different scenarios for the preparation of flood hazard and flood risk maps for the Antalya Basin. In these scenarios, hydrographs calculated for recurrence intervals of 50, 100, and 500 years were used as boundary conditions in the model, and flood simulations were performed. As a result of these studies, the hazard and risk status of different regions within the basin were determined based on water levels. The "Flood Hazard and Risk Maps" produced in this way provided insights into which areas are under threat, and these results were subsequently evaluated to conduct an intervention capacity analysis and a flood risk analysis.

The intersection areas of the project route and the 500-year recurring flood risk zones determined within the scope of the The Flood Risk Management Plan are shown in Figure VIII.5

Within the scope of this plan, Antalya Metropolitan Municipality and State Hydraulic Works (DSI) planned to implement various flood control measures in risky areas intersecting with the project route — on Manavgat Stream, northern part of Köprüçay and Alara Stream. Within this scope, measures such as improvement of irrigation channels and river connections and roads, reinforcement of dikes, regulation of river beds and construction of sea outlet structures have been completed between 2017 and 2022. An updated Flood Management Plan is expected to be published in recently 2025.

Culverts are drainage structures designed to allow water from natural channels—such as dry stream beds or small streams activated by rainfall—to pass beneath roads without causing damage. If culverts are not properly sized, intense rainfall can lead to excessive water accumulation in these channels, potentially overtopping the roadway. This may result in road closures, erosion of the embankment, and a reduction in the bearing capacity or stability of the embankment and its foundation. It is important to note that pavement deterioration around culverts—such as settlement or deformation—is often linked to insufficient culvert design. Furthermore, historical data shows that undersized culverts can contribute to downstream flooding. Therefore, drainage designs for highway systems must consider potential flood scenarios to ensure protection of the road infrastructure and nearby properties.

Within the scope of the project, a Hydraulic–Hydrological Study Report was prepared by Mega Mühendislik Müşavirlik A.Ş. in 2024.

According to the findings and planning framework outlined in the Hydraulic–Hydrological Study Report, the catchment area was delineated in the hydrologic studies, and floods with 10-,100, and 500 years were extracted with rational, synthetic unit hydrograph for 305 culverts. In the Hydraulic–Hydrological Study Report prepared within the scope of the Project, the bridges, viaducts and all culverts, the precipitation data of the region and the 10, 100 and 500 year recurring flow amounts of the river or stream bed on which each structure is located were calculated. As a result of these calculations, the relevant art structure was designed in such a way that the worst case maximum flow of the river bed to be crossed is not obstructed. The flow quantities used in the calculations and the flow quantities and maximum flows given in the Antalya Basin Flood Risk Management Plan were also used in the Hydraulic–Hydrological Study Report and the flood risk assessment of the Project was carried out in all art structures at all river and dry stream bed crossings. In addition in the desing stage of the Project, Hydraulic–Hydrological Study Report is approved by the General Directorate of DSİ and during this approval process, it is checked whether the design of the art structures (bridges, viaducts and culverts) in the design phase of the Project meets the worst case flow amount.

The Project design includes engineering structures such as tunnels, viaducts, underpasses, overpasses and culverts. All of these infrastructure units will be designed according to the Technical Specifications of General Directorate of Infrastructure Investments and other applicable standards including flood risks, as an internal adaptation.

In the scope of the Project;

- Consultations will be held with DSI and SYGM regarding the hydrological studies and any additional studies will be conducted upon the opinions of these institutions prior to the construction phase.
- during the construction phase, the surface drainage and site runoff, particularly in heavy rainy seasons will be properly managed by constructing temporarily or permanent channels which were designed to manage maximum flow capacity against the flood risk;
- at the construction areas without cover, ground will be seeded and the areas with highest slopes will be flattened to prevent erosion and sediment transport with surface run-off water;
- During operation it is essential that the water intake structures, canals and other structures be regularly inspected and be periodically maintained to ensure proper conveyance of water, avoid stagnation and prevent flooding and damages.

Moreover, Emergency Response Plans (ERP) will be prepared both for the construction phase and operation phases in order to prevent the damages that can be caused by flood. Also, necessary trainings related to flood will be given to the workers for both phases of the Project.

Figure VIII.5 Map Showing The Intersection of Q500 Flood Risk Maps And The Project Route

VIII.2.2.3. Groundwater

Groundwater is the water present beneath Earth's surface in soil pore spaces and the fractures of rock formations. A unit of rock or an unconsolidated deposit is called an aquifer when it can yield a usable quantity of water. Groundwater is recharged to the surface naturally; natural discharge often occurs at springs and seeps and can form oases or wetlands. Groundwater is usually withdrawn for agricultural, municipal, and industrial use by extraction wells.

Groundwater is often cheaper, more convenient, and less vulnerable to pollution than surface water. Therefore, it is commonly used for public water supplies. Groundwater is managed and controlled by State Hydraulic Works under the Ministry of Agriculture and Forestry in Türkiye.

According to the research of the State Hydraulic Works, according to the annual groundwater potential by basins, the groundwater operating reserve of the Antalya basin for 2020 was determined as 576.3 hm^3. The usable water potential of the basin is also found to be 12,9 $x10^9$ m^3/year considering the operational reserves of ~13 $x10^9$ m^3/year usable surface water and 576$x10^6$ m^3/year groundwater *(State Hydraulic Works, 2020*).

Antalya province exhibits a distinct karst character with Mesozoic aged limestones, which are widely observed around the Beydağları and Taşeli Plateau, especially in the southern foothills of the Western Taurus Mountains. These carbonate units, thanks to their high solubility potential, have formed advanced karst morphologies and consequently complex hydrogeologic systems. Karst aquifers are characterized by their high permeability and rapid groundwater flow, but are also highly susceptible to contamination due to their limited natural filtration capacity. Systems such as Kırkgöz, Düden and Kurşunlu, which are the main karst springs in Antalya, are of critical importance in both drinking water supply and protection of ecosystem integrity with their high flow rate and low mineralization waters. The high flow variability, sensitivity to precipitation regime and short hydraulic response times observed in these systems reveal the dynamic nature of karst aquifer behavior and necessitate effective monitoring of hydrogeological processes in the region. Those karstic formations described above have not the intersection with the main project route and the auxillary facilities needed for the realization of the project.

The hydrogeological properties of the geological units within the Project route vary depending on their lithological composition and structural status. In this context, while some units show important aquifer properties in terms of groundwater storage and transmission, some of them are weak aquifers or aquifers due to their low permeability. Groundwater fed from the mountainous regions in the north moves along the valleys and heads south towards the Mediterranean coast.

Ophiolitic Melange: The unit consisting of sandstone, claystone, micritic limestone, recrystallized limestone, oolitic limestone blocks and gabbro, diabase and altered serpentinites, has the ability to trap and transmit groundwater due to its fractured and fractured structure and is semi-permeable-permeable.

Sugözü Formation: The unit consists of shale and marbles and is impermeable-semi-permeable.

Aksu Formation: The unit consists of claystones, siltstones, sandstones and limestones; they are semi-permeable-impermeable because they have less fractured-fractured structure.

Çakallar Formation: The unit consisting of clayey limestone-limestones has semi-permeable-permeable properties due to its fractured-fractured structure and has the ability to trap and transmit groundwater within its structure.

Karpuzçay Formation: Consisting of clayey limestone-limestones, the unit has a fractured-fractured structure and has the characteristics of trapping and transmitting groundwater and is semi-permeable-permeable.

Eskiköy Formation: The unit consisting of pebbles, sandstones, fractured, fractured and granular structure has the characteristics of trapping and transmitting groundwater and is semi-permeable-permeable.

Yenimahalle Formation: The unit consisting of conglomerates, claystones, siltstones and sandstones is semi-permeable.

Slope Rubble: The unit consisting of clay, silt, sand, gravel-blocks and clay, silt, sand, gravel-blocks observed at the foot of steep slopes, has the characteristics of trapping and transmitting groundwater and is semi-permeable-permeable.

Alluvium: The unit, consisting of clay, silt, sand, gravel, and blocks, observed in the creek and valley floors, has the characteristics of both trapping and transmitting groundwater, and is semi-permeable to permeable.

Groundwater pollution most often results from improper disposal of wastes on land. Primary sources include industrial and household chemicals and landfill leachate, excessive fertilizers and pesticides used in agriculture, industrial waste lagoons, tailings and process wastewater from mines, leaking underground oil storage tanks and pipelines, sewage sludge and septic systems.

Considering that groundwater could be used as domestic water needs at campsite facilities the nearest groundwater resources were studied within the scope of this study. The quality of the groundwater is presented in the next section. The hydrogeology map and legend of the project are shown in Figure VIII.6 and Figure VIII.7, respectively.

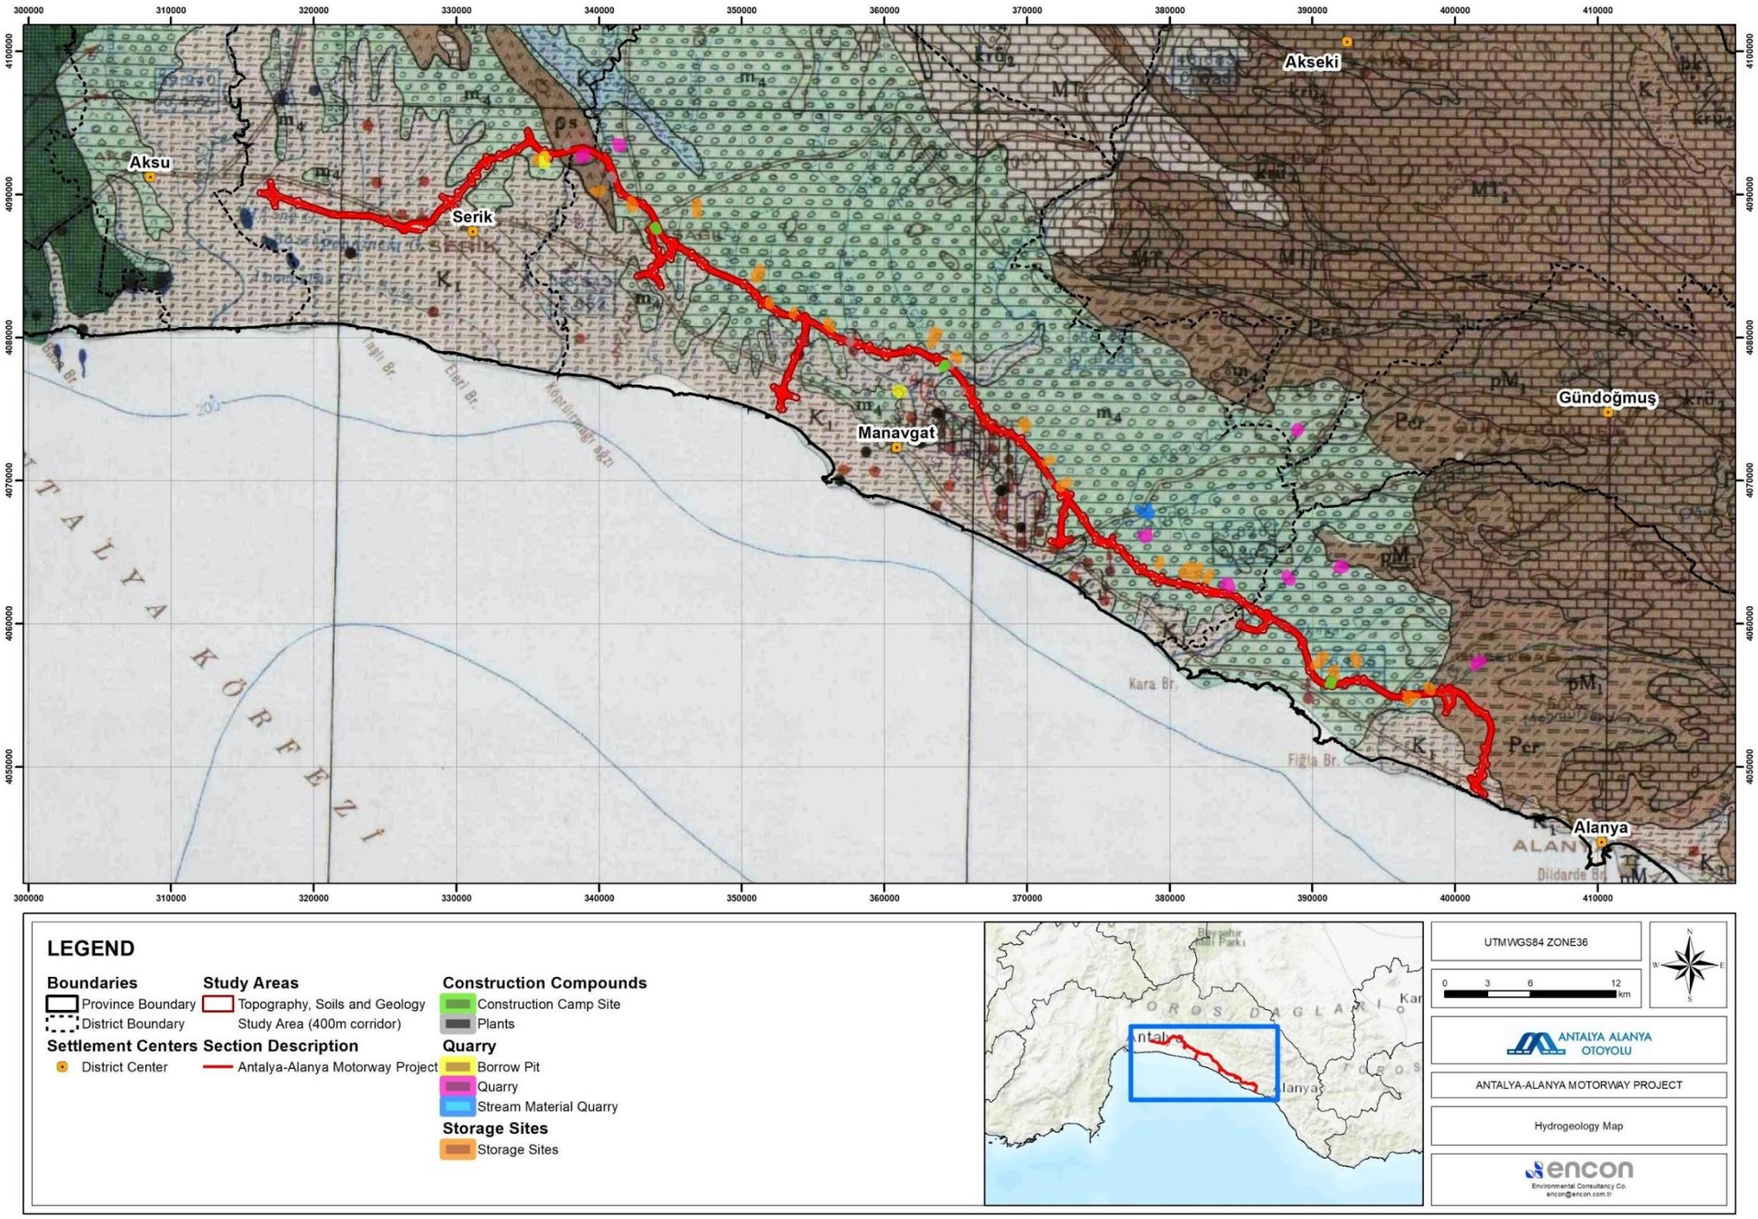

Figure VIII.6 Hydrogeology Map

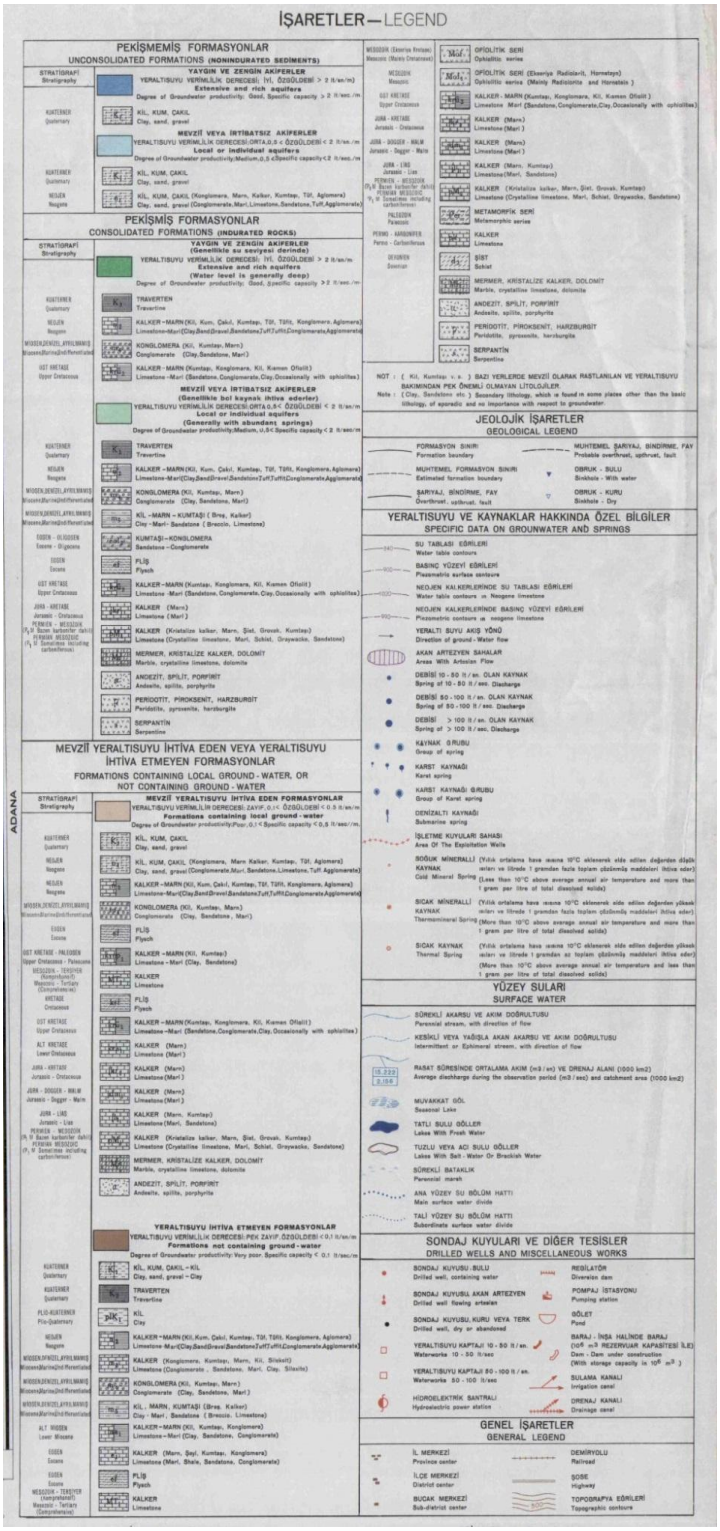

Figure VIII.7 Legend of the Hydrogeology Map

VIII.2.3.Field Surveys and Findings

A water quality assessment survey was undertaken in the scope of the ESIA studies to establish a description of the baseline conditions through Project route. In this regard, samples are taken, and relevant analyses were conducted by ENCON Laboratory Inc. in September and December 2024. The coordinates of the groundwater and surface water sampling points and corresponding KMs of the project route are given in Table VIII.3 and Table VIII.4, respectively.

Table VIII.3 Groundwater Quality Sampling Stations

Sampling Station	Location / Km	Coordinates

Surface water sampling locations were selected from the main streams that intersect the project route, focusing on areas where the project activities may potentially influence water quality. Similarly, groundwater sampling points were determined based on the potential impact zones and with consideration of the local hydrogeological setting. In this context, the selection process took into account the permeable, semi-permeable, and impermeable lithologies along the project route, to ensure that different hydrostratigraphic units are adequately represented. This integrated approach aims to provide a comprehensive understanding of the baseline conditions of both surface water and groundwater resources, particularly in environmentally sensitive areas and at key water crossings. The locations of water quality sampling are presented in Figure VIII.8. and, locations of water quality sampling locations with hydrological and hydrogeological features map, is presented in Figure VIII.9

According to the Surface Water Quality Regulation, a water resource can be classified into one of the three classes provided in Annex-5, Table 2 (Quality Class Criteria of Inland Surface Water Resources According to General Chemical and Physicochemical Parameters), only if the measured values of all parameters comply with the criteria for that class. Consequently, the lowest water quality class observed for any parameter determines the overall class of the water resource, even if other parameters suggest higher quality (with Class III being the lowest).

The threshold values that define each water quality class, as specified in Annex-5, Table 2 of the Regulation, are presented in Table VIII.5 and Table VIII.6 below, alongside the measurement and analysis results for each parameter at the water quality sampling stations. Samples taken from locations SW-1 through SW-12 were analyzed for all relevant parameters listed in Annex-5, Table 2.

	December 2024	Class III	Oil and Grease, Sulphur, Endosulfan
SW-9	September 2024	Class III	Oil and Grease, Sulphur, Endosulfan
	December 2024	Class III	Oil and Grease, Sulphur, Endosulfan
SW-10	September 2024	Class III	Oil and Grease, Sulphur, Endosulfan
	December 2024	Class III	Oil and Grease, Sulphur, Endosulfan
SW-11	September 2024	Class III	Oil and Grease, Sulphur, Endosulfan
	December 2024	Class III	Oil and Grease, Sulphur, Endosulfan
SW-12	December 2024	Class III	Oil and Grease, Sulphur, Endosulfan

When analysis results given in Table VIII.5 and Table VIII.6 are evaluated with respect to the standards provided in the Surface Water Quality Regulation, the water quality class of all samples, for September and December 2024 sampling periods, was determined as Class III. The details of the parameters defining the given water classes are provided in Table VIII.7.

As seen in Table VIII.7, all surface water samples collected in September and December 2024 fall under Class III according to the Surface Water Quality Regulation. The dominant parameters determining the classification are Oil and Grease and Sulphur, consistently observed across all sampling stations. This indicates a widespread, likely non-point source pollution pattern, potentially associated with diffuse agricultural or transportation-related runoff.

In particular, the presence of Total Kjeldahl Nitrogen, Ammonium Nitrogen, and Biochemical Oxygen Demand (BOD) at SW-1, SW-2, and SW-4, though limited, suggests intermittent organic or nutrient-based pollution inputs, possibly from nearby domestic or agricultural activities.

According to Table VIII.8 and Table VIII.9, when the parameters are evaluated based on the values specified in Table 5 of Annex-5 of the Regulation on Surface Water Quality, it is observed that the majority of the examined pollutants are below the environmental quality standards. In particular, Alachlor, Anthracene, Atrazine, Benzene, Diuron, and many pesticides were not detected at any of the sampling stations. However, concentrations of Lead (especially at SW-5, SW-6, SW-10, and SW-12), Mercury (at SW-6 and SW-8), and Nickel (at SW-2, SW-5, SW-6, SW-9, and SW-12) exceeded the threshold limits.

In September and December 2024, eight groundwater samples were collected along the Project route to assess the groundwater quality in the area, in addition to surface water samples. To evaluate baseline groundwater quality conditions, Annex-5, Table 2 of the Surface Water Quality Regulation was used, ensuring consistency in evaluating both surface and groundwater quality. The results of the groundwater analyses are provided in Table VIII.10 and Table VIII.11.

The analysis results for the groundwater monitoring stations, presented in Table VIII.10, were evaluated solely according to the environmental quality standards in Annex-5, Table 2 of the Surface Water Quality Regulation. Exceedances of Class III limits for parameters such as conductivity, oil and grease, total nitrogen, fluoride, and sulfur were noted at some stations; meanwhile, parameters such as color, pH, dissolved oxygen, COD, BOD, ammonium nitrogen, orthophosphate phosphorus, and total phosphorus predominantly fell within Class I and II ranges. Due to oil and grease and Sulphur parameters, the water quality of eight locations was defined as Class III.

The exceeding of water quality limits for certain parameters, such as conductivity, oil and grease, total nitrogen, fluoride, and sulfur, can be attributed to various factors. These include pollution from agricultural activities, such as the excessive use of fertilizers and pesticides, industrial discharges, urban runoff, and improper waste management.

In Table VIII.11, the limit values defined by national regulations (Regulation on Water Intended for Human Consumption; Regulation on the Protection of Groundwater Against Pollution and Deterioration), international standards (WHO Guidelines for Drinking-water Quality; EU Directive 2020/2184; Directive 2006/118/EC), and the project standard are shown, and the parameters exceeding these limits are indicated.

Detailed water quality analysis reports are presented in Annex-2.

According to Table VIII.11, the values exceeding the parameters as follows,

- The Lead and Compounds parameter exceeded the permissible limit at GW-1 in September 2024.
- The Manganese parameter exceeded the permissible limit at GW-6 in September 2024.
- The pH parameter exceeded the permissible limit at GW-6 in September 2024.
- The Fluoride parameter exceeded the permissible limit at GW-6 in both September and December 2024.
- The Manganese parameter exceeded the permissible limit at GW-7 in December 2024.
- The Cadmium and Compounds parameter exceeded the permissible limit at GW-7 in September 2024.
- The Manganese parameter exceeded the permissible limit at GW-8 in September 2024.

Hydrogeochemical Study

In order to understand the water-rock interactions and the fundamental hydrogeochemical characteristics of the basin, hydrochemical analyses were conducted on groundwater samples. In hydrogeochemical studies, various graphical methods are employed to represent the concentration or relative abundance of ions in individual water samples, providing insight into the origin and classification of the waters. Among these, the Piper diagram is one of the most widely used approaches. This diagram consists of three separate fields: the cation triangle, in which the relative abundances of $Na^+ + K^+$, Ca^{2+}, and Mg^{2+} (expressed in %meq/L and summing to 100%) are plotted; the anion triangle, which reflects the proportions of $HCO_3^- + CO_3^{2-}$, Cl^-, and SO_4^{2-}; and a central diamond-shaped field where projections from the two triangles intersect to define a compositional point. Through this diagram, groundwater samples can be classified into hydrochemical facies.

In this study, to evaluate the chemical characteristics of the groundwater, major cations (Calcium – Ca^{2+}, Magnesium – Mg^{2+}, Sodium – Na^+, and Potassium – K^+) and major anions (Carbonate – CO_3^{2-}, Bicarbonate – HCO_3^-, Sulfate – SO_4^{2-}, and Chloride – Cl^-) were analyzed and interpreted using Piper and Schoeller diagrams.

Piper Diagram

The results of the analysis of the sample points are shown in the Piper Diagram in Figure VIII.10

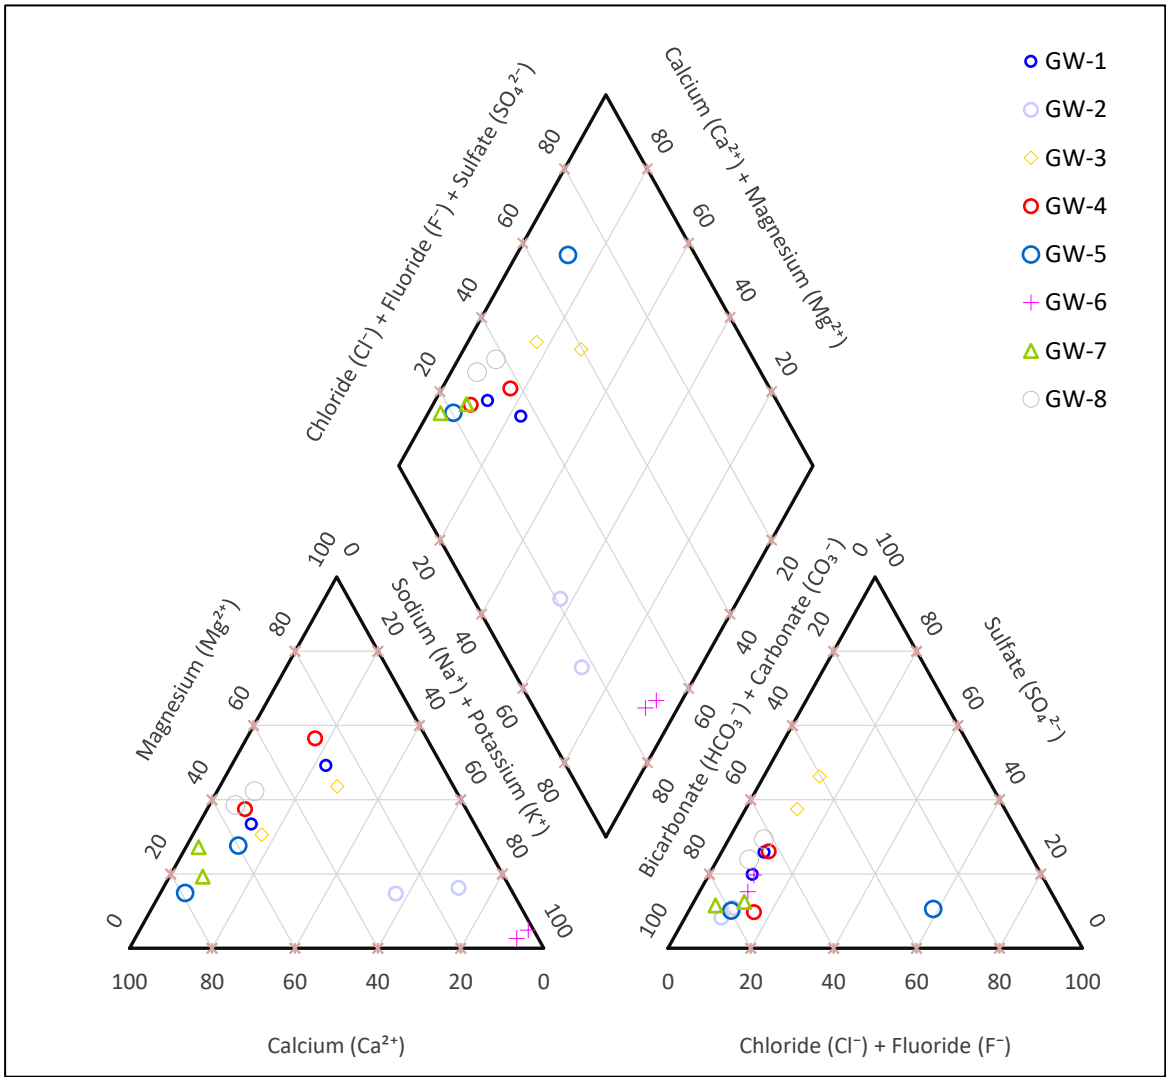

Figure VIII.10 Piper Diagram

GW-1

September, 2024
Cations: Ca^{2+} 53.78%, Mg^{2+} 33.48%, Na^{+} 11.98%, K^{+} 0.76%Anions: HCO_3^{-} 73.74%, SO_4^{2-} 17.25%, Cl^{-} 9.01%Facies: Ca–HCO_3
Interpretation: Classified as a Ca–HCO_3 water type, indicating recharge dominated by carbonate dissolution.

December, 2024
Cations: Mg^{2+} 49.22%, Ca^{2+} 27.92%, Na^{+} 21.38%, K^{+} 1.49%Anions: HCO_3^{-} 68.27%, SO_4^{2-} 22.69%, Cl^{-} 9.03%Facies: Mg–HCO_3
Interpretation: Mg–HCO_3 facies, pointing to dolomitic influence or longer residence time.

GW-2

September, 2024
Cations: Na^+ 56.72%, Ca^{2+} 28.38%, Mg^{2+} 14.70%, K^+ 0.21%Anions: HCO_3^- 82.00%, SO_4^{2-} 9.21%, Cl^- 8.79%Facies: Na–HCO_3
Interpretation: Na–HCO_3 facies is clear, indicating ion exchange or deep groundwater influence.

December, 2024
Cations: Na^+ 70.96%, Mg^{2+} 16.25%, Ca^{2+} 12.42%, K^+ 0.37%Anions: HCO_3^- 85.62%, Cl^- 7.43%, SO_4^{2-} 6.95%Facies: Na–HCO_3
Interpretation: Strong Na–HCO_3 ; dominant sodium reflects advanced ion exchange processes.

GW-3

September, 2024
Cations: Ca^{2+} 52.77%, Mg^{2+} 30.62%, Na^+ 15.85%, K^+ 0.76%Anions: HCO_3^- 55.03%, SO_4^{2-} 33.79%, Cl^- 11.18%Facies: Ca–HCO_3 with secondary SO_4
Interpretation: Ca–HCO_3 facies dominates; elevated SO_4 reflects minor influence from evaporite dissolution.

December, 2024
Cations: Mg^{2+} 41.17%, Ca^{2+} 26.41%, Na^+ 25.35%, K^+ 1.08%Anions: HCO_3^- 45.89%, SO_4^{2-} 41.46%, Cl^- 12.65%Facies: Mixed Mg–HCO_3–SO_4
Interpretation: Mixed facies trending toward Mg–SO_4–HCO_3 zone, consistent with sulfate enrichment.

GW-4

September, 2024
Cations: Ca^{2+} 52.02%, Mg^{2+} 36.53%, Na^+ 10.49%, K^+ 0.24%Anions: HCO_3^- 74.86%, Cl^- 13.08%, SO_4^{2-} 12.06%Facies: Ca–HCO_3
Interpretation: Classic Ca–HCO_3 facies indicates fresh recharge dominated by carbonate dissolution.

December, 2024
Cations: Mg^{2+} 54.71%, Ca^{2+} 25.90%, Na^+ 15.35%, K^+ 4.04%Anions: HCO_3^- 67.32%, SO_4^{2-} 22.81%, Cl^- 9.87%Facies: Mg–HCO_3
Interpretation: Facies shift to Mg–HCO_3 dolomitic water-rock interaction.

GW-5

September, 2024
Cations: Ca^{2+} 76.78%, Mg^{2+} 14.46%, Na^+ 7.41%, K^+ 1.35%Anions: HCO_3^- 78.50%, SO_4^{2-} 13.24%, Cl^- 8.26%Facies: Strong Ca–HCO_3
Interpretation: Ca–HCO_3, consistent with recently recharged, unpolluted groundwater.

December, 2024
Cations: Ca^{2+} 62.05%, Mg^{2+} 28.66%, Na^+ 8.76%, K^+ 0.53%Anions: Cl^- 50.19%, HCO_3^- 32.00%, SO_4^{2-} 17.81%Facies: Ca–Cl
Interpretation:Ca–Cl ; likely due to saline intrusion or anthropogenic influence.

GW-6

September, 2024
Cations: Na^+ 92.55%, Ca^{2+} 4.59%, Mg^{2+} 2.39%, K^+ 0.47%Anions: HCO_3^- 78.83%, SO_4^{2-} 10.83%, Cl^- 10.34%Facies: Na–HCO_3
Interpretation: Strong Na–HCO_3 dominance, indicating ion exchange and deeper circulation.

December, 2024
Cations: Na^+ 93.40%, Mg^{2+} 4.28%, Ca^{2+} 1.11%, K^+ 1.21%Anions: HCO_3^- 72.65%, SO_4^{2-} 18.08%, Cl^- 9.27%Facies: Na–HCO_3
Interpretation: Na–HCO_3 type remains dominant; SO_4 rise confirms mineral dissolution.

GW-7

September, 2024
Cations: Ca^{2+} 65.49%, Mg^{2+} 25.76%, Na^+ 2.66%, K^+ 6.08%Anions: HCO_3^- 82.48%, SO_4^{2-} 12.82%, Cl^- 4.70%Facies: Ca–HCO_3
Interpretation:Ca–HCO_3 type with fresh recharge characteristics.

December, 2024
Cations: Ca^{2+} 60.99%, K^+ 16.21%, Mg^{2+} 16.22%, Na^+ 6.59%Anions: HCO_3^- 74.09%, SO_4^{2-} 16.08%, Cl^- 9.83%Facies: Ca–HCO_3
Interpretation: Ca–HCO_3 facies; elevated K remains secondary.

GW-8

September, 2024
Cations: Ca^{2+} 51.25%, Mg^{2+} 36.01%, Na^+ 5.70%, K^+ 7.04%Anions: HCO_3^- 70.63%, SO_4^{2-} 23.01%, Cl^- 6.36%Facies: Ca–HCO_3
Interpretation: Ca–HCO_3 dominance with minor SO_4.

December, 2024
Cations: Ca^{2+} 44.24%, Mg^{2+} 38.60%, Na^+ 7.78%, K^+ 9.38%Anions: HCO_3^- 63.03%, SO_4^{2-} 30.02%, Cl^- 6.95%Facies: Ca–HCO_3–SO_4 transitional
Interpretation: Shift toward Ca–SO_4–HCO_3 zone, likely reflecting increased mineral interaction.

Schoeller Diagram

The Schoeller diagram is a graphical method used to classify groundwater based on its chemical characteristics and intended use, facilitating the interpretation of water origin and similarity. One of its key applications is the estimation of aquifer lithology within a groundwater system, essentially identifying the rock types with which groundwater has interacted. According to Schoeller (1955), waters are classified based on the concentrations of chloride, sulfate, and carbonate plus bicarbonate ions.

In the construction of the Schoeller semi-logarithmic diagram, ion concentrations (in milliequivalents per liter, meq/L) are plotted on the vertical logarithmic axis, while the ions themselves are evenly spaced along the horizontal axis. The chemical composition of groundwater is primarily controlled by the geochemical properties of the rocks it contacts. Waters originating from the same reservoir or recharge

area, and having similar lithological interaction, tend to display comparable patterns or “peaks” on the diagram.

The Schoeller Diagram thus provides a means to compare and classify waters by plotting the concentrations of major cations and anions—typically Mg^{2+}, Ca^{2+}, Na^{+}, K^{+}, Cl^{-}, HCO_3^{-}, and SO_4^{2-}—on a semi-logarithmic scale. Each water sample produces a distinct profile based on its ionic composition, enabling clear visualization and comparison of chemical similarities or differences between samples. When profiles overlap or show similar trends, it suggests a common hydrogeochemical origin or similar aquifer conditions. The results of the analysis of the sample points are shown in the Schoeller Diagram in Figure VIII.11.

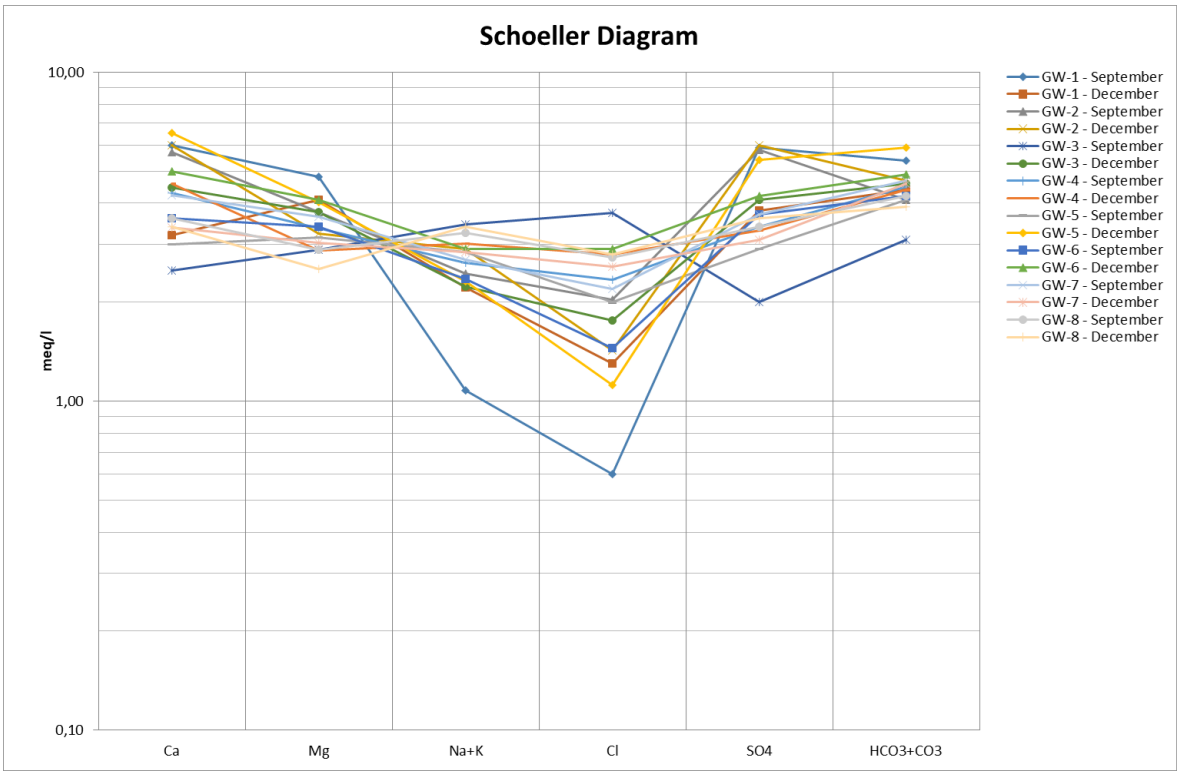

Figure VIII.11 Schoeller Diagram

This Schoeller diagram reveals that the hydrogeochemical types of the samples are mostly of the Ca-Mg-HCO_3 type, with no major seasonal variation. The similarities in the diagram suggest that the water comes from the same aquifer or similar geological units.

US Salinity Diagram

Groundwater may contain excessive amounts of undesirable substances such as salts, and thus should be evaluated prior to its use for irrigation purposes. High concentrations of dissolved ions in irrigation water can adversely affect both plants and agricultural soils through various physical and chemical interactions, ultimately leading to reduced crop yield. Although numerous parameters influence irrigation

water quality, their impacts can vary—some may not affect certain plant species, while others can have detrimental effects. For example, sodium ions (Na^+) present in saline water can replace calcium ions (Ca^{2+}) in the soil matrix, reducing soil permeability and aeration. This, in turn, hinders plant growth. Therefore, assessing the quality of irrigation water is essential for maintaining agricultural productivity. In this study, the classification of water samples was conducted using the 'U.S. Salinity Laboratory Diagram' developed by Richards (1954). This diagram is based on two key parameters: Electrical Conductivity (EC) measured in µS/cm at 25°C, and the Sodium Adsorption Ratio (SAR). The SAR values in this study were calculated using the formulas provided below.

Figure VIII.12 US Salinity Diagram

According to the Figure VIII.12, all water samples were located in the C2S1 and C3S1 zones. This indicates that the studied waters are generally of suitable quality for irrigation purposes. The samples in the C2S1 zone are waters with moderate salinity and low sodium hazard. Such waters are agriculturally safe as they do not carry the risk of sodium accumulation in the soil and can be easily used for irrigation of various crops. However, regular monitoring is recommended to ensure that soil salinity does not increase over time.

The samples in the C3S1 zone have higher salinity levels but still contain low sodium content. These waters are particularly suitable for crops with high salt tolerance (e.g. barley, cotton, corn). However, due to the high salinity, good drainage conditions should be ensured in lands irrigated with these waters and salt accumulation in the soil should be monitored regularly. Otherwise, soil fertility may decrease over time.

Overall, both groups have low risk for sodium and therefore low potential for soil structure degradation. Therefore, the vast majority of available water samples can be safely used for irrigation purposes, but caution is recommended for plants with high salt sensitivity and regular analysis of soil and water.

Charts showing the anion and cation distributions of the groundwater samples is shown in Figure VIII.13

VIII.2.4.Wastewater Management

During the land preparation and construction activities, wastewater will be generated from construction sites and accommodation facilities for workers (campsite, kitchen, cafeteria, etc.). The basic approach will be to reuse the wastewater generated by project activities in the activity cycle during construction. This approach will not require any water discharge to environmental media. Especially for the reuse of wastewater generated in concrete batching plants, three-compartment settling ponds will be constructed. In order to reuse the water used during vehicle washing operations, vehicle washing stations will be established and the necessary pools and installations will be constructed for the reuse of water at these stations.

For the areas where reusing will not be an option, water should be treated to reduce or eliminate the contaminants before being discharged to receiving environment.

According to the data published by TurkStat (2022), the daily average municipal wastewater generation by a person is 197 L/capital/day in Türkiye, 318 L/capital/day in Antalya. Assuming that the wastewater consumption at the construction site is 70% of the consumption under normal conditions, the wastewater produced by one person per day is calculated as 223 liters. The number of people planned to be employed during the construction period of the project is 3300, and it is accepted that 1100 people will work on a construction site. In this context, Table VIII.12 indicates the total amount of wastewater will generated during the construction phase.

Table VIII.12 Amount of Wastewater to be produced in the Construction Phase

Location	Maximum Personnel* (persons)	**Total Amount of Daily Wastewater Generation (L/day)
1.Camp Site	1,250	250,875

2.Camp Site	1,250	250,875
3.Camp Site	1,250	250,875
Total	**3,750**	**752,625**

** Number of Maximum Personnel Anticipated including contractor and sub-contractors (provided by Project Sponsor).*
***Detailed calculations are provided in Chapter IX Use of Resources and Waste Management.*

Throughout the project construction phase, package Wastewater Treatment Plants (WWTP) and non-leaking septic tanks were planned and to be constructed for each construction campsite. Although it is accepted that 1,100 people are planned to work in a campsite during the construction period of the project, each package WWTP will have a capacity equivalent to the maximum number of people, 1,250 people (including personnel of contractor and sub-contractors). Therefore, no significant impact is expected due to domestic wastewater discharges.

All the permits related to WWTP and environmental has applied as of June/2025 and waiting for the approvals. Discharge points of WWTP's permit approval has been granted from Turkish State Hydraulic Works (DSİ).

Treated wastewater shall be analyzed in order to ensure that the quality and quantity of the wastewater to be discharged will be in compliance with the limit values indicated in national and international regulations. In addition, necessary permits will be obtained from regulating administrations. The quality of the wastewater will be in compliance with the limit values indicated in Regulation on of Control Water Pollution and IFC standards, which are given in Table VIII.13. It is planned to reuse treated water to prevent dusting.

Table VIII.13 Domestic Wastewater Discharge Requirements

Parameter	Turkish Legal Requirement ([a])	IFC ([b])
	2-hr Composite Sampling	
Biochemical Oxygen Demand (BOD_5) (mg/L)	50	30
Chemical Oxygen Demand (COD) (mg/L)	160	125
Total Suspended Solids (TSS) (mg/L)	60	50
pH	6-9	6-9
Total Nitrogen (mg/L)	-	10
Total Phosphorus (mg/L)	-	2
Oil and Grease (mg/L)	-	10
Total Coliform Bacteria MPN([c])/100 ml	-	400

([a]) Water Pollution Control Regulation, Table 21.1 Domestic Wastewater Discharges (Class 1: BOD load 5-120 kg/day, Population: 84-2000)
([b]) Table 1.3.1-Indicative Values for Treated Sanitary Sewage Discharges, IFC Environmental, Health, and Safety General Guidelines, April 30, 2007.
([c]) MPN: Most Probable Number

In operation phase, rest and maintenance areas and toll booth area will be the sources of wastewater generation. Generated wastewater may contain organic and inorganic pollutants, suspended solids,

heavy metals or toxic materials, etc. Wastewater will be either discharged into the local/municipal sewage network or treated prior to discharge to the suitable receiving environment or collected onsite and transported by tanker for disposal at the local sewage treatment works There is no planned discharge to the riverbeds (dry or running) that are used for the drinking water supply to the settlements. The total amount of wastewater expected to be generated during the operation phase will be calculated by the project sponsor after sharing the number of employees and visitors during the operation period. How to calculate the amount of wastewater to be generated in the facilities to be used during the operation period is presented in Chapter VII.

VIII.3. Potential Impacts

In order to assess potential impacts of the Project on water resources, the project is considered in two phases: Land Preparation and Construction Phase and Operation Phase. In this way, relevant impacts are evaluated separately for each phase since the project activities and potential releases from these activities are different for each phase.

VIII.3.1. Land Preparation and Construction Phase

Potential impacts on water resources during the land preparation and construction phase are generally expected to be more significant than the ones during operation phase for motorway projects. The main sources of land preparation and construction phase impacts of a motorway project on water resources are typically suspended sediment in runoff waters from the work sites and accidental spillages of hazardous materials from construction activities and machinery.

VIII.3.1.1. Impacts on Surface Water

Potential impacts on surface water bodies and quality can mostly be considered temporary.

These impacts can be listed as follows:

- Construction activities on existing surface water bodies, such as rivers, creeks, drainage systems, or irrigation channels, may lead to the permanent alteration or destruction of these water features if proper design and construction management precautions, including reinstatement measures, are not implemented.
- Silty, soiled, and high turbidity water would arise from construction activities, which might contaminate surface waters. Main construction activities that may cause these impacts are;
    - excavation
    - soil stockpiling
    - quarry activities
    - plant and wheel washing
    - road construction
    - washing of finished road surfaces to remove accumulated soil

- Spills of hazardous substances including fuel, oils, lubricants and cement might take place at construction sites, refueling site or storage depot and reach to close by surface and groundwater. These would affect the water quality such that aquatic life (mainly fish) and downstream users might also be affected.
- Bitumen and materials used for waterproofing of concrete surfaces will be used during the construction phase of the Project. These materials are also a contamination source for surface water, especially when they are mixed with surface runoff upon precipitation and reach a surface water body.
- All wastewaters from construction activities (sanitary or process) pose a risk to the water environment if not treated before discharge.

VIII.3.1.2.

VIII.3.1.3. Impacts on Groundwater

The potential impacts on groundwater would be on both water quality and water quantity (groundwater levels) in the area. These can be listed as follows:

- Some deeper excavation works may require permanent dewatering of a groundwater component.
- During earthworks and other soil-related activities; in sections cut into the bedrock or shallow overburden, any fissure permeability is at risk of blockage by infiltrating sediment/fines.
- Especially on areas with shallow overburden, accidental discharges of hazardous materials to the ground can contaminate aquifers.
- Site clearance, earthwork, spillages/leakages from construction sites, and refueling vehicles may contaminate aquifers.
- All wastewaters from construction activities (sanitary or industrial) pose a risk to the water environment if not treated before discharge.

VIII.3.2.Operation Phase

Potential impacts on water resources during the operation/use of the motorway are generally more limited than construction phase, and there are temporary, one-time and long term impacts.

VIII.3.2.1. Impacts on Surface Water

Impacts on Surface Water Quality

- Maintenance activities like using de-icing agents may affect surface water quality if they reach any close surface water, but this impact will be temporary.
- During the operation of the motorway, spills during road accidents and from filling stations might be of concern. This type of water pollution risk is high within all road sections close to surface water bodies. However, this type of impact would be temporary since accidents and/or spillages should be considered as one-time events.
- Routine deposits (tire and brake deposits, hydrocarbons from engines, liquid exhaust emissions etc.) of vehicles travelling on motorway and leakage of road body itself (tar soils) and road marking materials have the possibility to impact nearby surface water quality. As these events are continuous, such impacts would be considered as permanent.

Structural Impacts on Surface Water

- Construction of viaducts, culverts, etc. might change the hydrological regime with potential impacts on the beds and banks of rivers (scour, erosion, deposition etc.).
- In case of inappropriate design, physical interference of a stream by the installation of culverts and roadways has the possibility to impact the hydrological regime of a stream.

Impacts on Drainage and Flooding

- The final structure of a motorway will increase the impermeable surface area because of its nature. That situation leads to an increase in the rate of surface water runoff, and high storm water flow rates can lead to erosion and flooding.

- During flood times, culverts, and diversion channels may impede flow. This situation causes an increase in the water level at the upstream of relevant structures.

VIII.3.2.2. Impacts on Groundwater

Impacts on Groundwater Quality

- Runoff from the road pavement is likely to contain some degree of silt/dust and pollutants from atmospheric deposition, vehicle emission, litter, and general road maintenance, as well as from possible accidental road spillage incidents. This runoff has the possibility to infiltrate into the groundwater and contaminate it.
- In areas where groundwater wells are located down-gradient and short distances from fill sections, and at fill sections where the subsoil thickness is shallow, surface water runoff has the potential to infiltrate into the subsoil and migrate to the groundwater.

Impacts on the Groundwater Table

- Deep cuttings are a necessity for Project in some areas. Deep cuttings may have impacts on the groundwater regime and also have subsequent impacts on groundwater abstraction wells.
- Groundwater recharge may decrease because of sealing of surfaces of motorway.

VIII.4. Mitigation Measures

Relevant mitigation measures according to potential impacts identified are described in this section. Impacts of the project should be mitigated by measures to be taken at different phases of project development and implementation. Therefore, mitigation measures to be considered are categorized into three phases, namely, design, land preparation and construction, and operation.

VIII.4.1. Design Phase

- General hydrological considerations/design of the Project will be in accordance with KGM design standards and AASHTO Highway Drainage Principles. In this regard, generally, 100-year flood flow will be taken into account on stream passage designs (Ref. State Highways Technical Requirements, Item 9.3). Minimum dimensions of all culverts will be 2m x 2m except discharge culverts. Culverts will be designed with one outlet whenever possible. Any change in the project design will be implemented once approved by KGM.
- Project elements will be located such that risks on groundwater would be minimized. Groundwater use for project activities would be planned to be limited and would be done only after getting relevant permissions from the authorities.
- In case of a need, new or replacement of irrigation structures will be constructed.
- In order to minimize changes in the hydrology and flow of water courses, design of structures will be done accordingly. The design will also ensure an appropriate capacity for culverts through embankments when flood plains are cut off.
- The design will be done in a way to minimize the risks of flooding. During the operation phase, Emergency Preparedness and Response Plan (See Annex-3) will be used to mitigate flood events.

- Storm water management practices that slow peak runoff flow, reduce sediment load, and increase infiltration, including vegetated swales (planted with salt-resistant vegetation), filter strips, terracing, detention ponds or basins, and infiltration trenches, will be planned.
- In order to limit the volume of water requiring specialized treatment (during land preparation and construction, and operation phases), segregation of liquid effluents, principally along industrial, sanitary, and stormwater categories, will be planned.
- Fish and terrestrial animal passages will be located in design where necessary.
- Appropriate designs and structures, such as viaducts will be used for stream and river crossings.
- Drainage projects have been developed to collect surface runoff along the Motorway by means of ditches and diversion of the collected water to the nearest receiving water bodies. The design criteria for the drainage system are in accordance with motorway standards.
- Pleas refer to Chapter 7 about the details of the drainage network.

VIII.4.2. Land Preparation and Construction Phase

VIII.4.2.1. Mitigation Measures for Surface and Groundwater Quality

- Equipment and vehicles will get their fuels at designated areas.
- Hazardous materials will not be stored within excavated areas. Handling of all hazardous materials will be supervised. Impervious bunds and other containment techniques will be used where hazardous materials are handled.
- Throughout the project construction phase, package Wastewater Treatment Plants (WWTP) and non-leaking septic tanks were planned and to be constructed for each construction camp site. All wastewater discharges from all components of construction will comply with relevant legal requirements.
- All wastewater discharges will comply with relevant Turkish legal requirements (Water Pollution Control Regulation 2004, No. 25687) and Project Standards before disposal, and relevant permits and monitoring shall in place.
- Wastewater from all construction compounds and the associated buildings will either be discharged into the local/municipal sewage network or treated on site before discharge to a suitable receiving environment (as allowed for under permit conditions) or collected on site and transported by tanker for disposal at the local sewage treatment works and wastewater discharge permit according to the provisions of the “Environmental Permit and License Regulation” (Official Gazette: 10.09.2014-29115) will be secured before operation of the plant.
- All wastewater produced during construction activities will be temporarily stored on site in suitable, leakage-proof and spill-proof above-ground storage tanks or similar containers based on available technology (non-corrosive and suitable for storing wastewater) and periodically collected by licensed companies appointed by AAOAİŞ and trucked to appropriate and licensed wastewater treatment/disposal facility authorized according to national regulations.
- The disposal of the wastewater collected by the vacuum trucks will be carried out at appropriate district municipal treatment facilities under a contractual agreement which contractual agreement will be reached before the installation of septic tanks. The frequency of vacuum truck wastewater removal will be recorded.
-
- Package wastewater treatment plants designed for the maximum number of employees will be used in construction campsites.
- The regular cleaning, maintenance, and inspection of package wastewater treatment plants will be ensured.
- The pipeline from the wastewater source to the package wastewater treatment plant will be robust enough to withstand heavy vehicle loads. This will prevent blockages and/or leaks.

- All wastewater discharges from all components of construction will comply with relevant legal requirements. Treated water will be reused where possible and feasible.
- For facilities with a small number of workers where a treatment plant is not feasible, septic tanks will be used, and these tanks will be frequently emptied by vacuum trucks.
- The disposal of the wastewater collected by the vacuum trucks will be carried out at appropriate district municipal treatment facilities under a contractual agreement. The frequency of vacuum truck wastewater removal will be recorded.
- When water quality criteria allow, stormwater will be managed as a resource for meeting the Project's water needs whenever feasible.
- Drainage water from excavations will be collected and treated to remove contaminants before discharging. Perimeter drains will be constructed around all working areas to collect potentially contaminated run-off and direct it to a system of settlement tanks before discharge in accordance with required permits. Direct discharge of contaminated run-off from work sites will not be allowed.
- Channels, bunds, and sandbag barriers will be used to provide direct run-off to the collection system.
- Biodegradable cleaning agents will be used to remove the asphalt residues.
- High sediment generating activities will be avoided, exposed surfaces and stored materials covered, if necessary, to reduce sediment erosion and reach surface waters.
- For any emergency during construction, Emergency Preparedness and Response Plan will be implemented.
- Exposure of areas of the open ground will be kept at a minimum in size and duration.
- All details related to wastewater management, including records, maintenance, cleaning frequencies, inspections, and responsible personnel, will be defined in the Water Quality, Wastewater and Stormwater Management Procedure.
- In case of groundwater utilization within the scope of the Project, necessary permits and approvals will be obtained from the General Directorate of State Hydraulic Works (DSİ), taking into account the adequacy and sustainability of the water resource. A detailed hydrogeological study will be carried out within the scope of the Project.
- Calculation of radius of impact on groundwater abstraction and discharge on natural flow system, groundwater dependent ecosystems and groundwater users will be analysed if applicable.
- Groundwater will not be used in areas at risk of contamination; in such cases, surface water sources or outsourced water sources will be used as an alternative.

VIII.4.2.2. Mitigation Measures for Surface Water Bodies and Channels

- Whenever and wherever possible, construction of viaducts, retaining walls, and other structures will be done during dry water season months.
- Fencing will be used in sensitive areas of rivers and drains for protection.
- Isolation techniques such as berming or diversion during construction to limit the exposure of disturbed sediments to moving water will be used during in-stream works.
- In order to protect small drains within construction areas, they will be covered with metal plates that construction machines can pass over.
- Stream crossing works will be carried out from the banks above the channel and avoiding direct intervention in the watercourse unless existing bank reinforcement needs to be replaced. The works will be undertaken during periods of low flow, and the duration of in-stream activities will be restricted.
- Use of grass turf from adjacent areas to cover the soil surface, use of erosion control blankets or mats, and other relevant soil erosion prevention measures will be implemented after the finalization of an earthwork.

VIII.4.2.3. Mitigation Measures for Water Ingress into the Tunnels

- The volume of water expected to enter the tunnels will be calculated before the construction area layout is finalized, and water management strategies will be based on this data.
- Tunnel water settling basins will be appropriately sized, taking into account these calculations and best practice guidance for settling basin design.
- Measures to prevent cement contamination of tunnel water will be clearly defined and described in detail. Water exiting the tunnels will be directed to settling basins with sufficient capacity to receive all surface runoff.
- After passing through the settling basins, the effluent will be discharged if the measured parameters meet discharge standards. If needed, and after achieving the required quality standards, the water will be reused within the system(e.g., for dust suppression, construction activities, etc.).

VIII.4.2.4. Mitigation Measures for Water Usage

- The water use of project activities would be planned to be limited and would be done only after getting relevant permissions from the authorities.
- For the reuse of wastewater generated in concrete batching plants, three-compartment settling ponds will be constructed.
- In order to reuse the water used during vehicle washing operations, vehicle washing stations will be established and the necessary settlement pools and installations will be constructed for the reuse of water at these stations. It is planned to reuse treated water to prevent dusting. Water used in concrete plants will be filtered in watertight sedimentation ponds and reused. These ponds will be frequently cleaned by the responsible person(s) according to the plan, thus preventing overflow.
- To reuse of wastewater generated in concrete batching plants, three-compartment settling ponds that each compartment will be 1 m depth, 2 m width and 3 m length should be constructed. The settlements in the settling ponds will be removed bi-weekly. In order to reuse the water used during vehicle washing operations, vehicle washing stations will be established and the necessary pools and installations should be constructed for the reuse of water at these stations.
- Treated wastewater will be analyzed to ensure compliance with relevant quality limit as defined in regulatory frameworks. The Project's approach to water management focuses on minimizing adverse environmental impacts and ensuring that all discharges meet established regulatory thresholds.

VIII.4.3. Operation Phase

VIII.4.3.1. Mitigation Measures for Surface and Groundwater Quality

- Sealed basement and bunds with a capacity of the 100% of the storage capacity of the largest tank will be used at fuel stores and other harmful substance stores.
- In case of any large-scale spill, absorbent materials within spill response kits will be used. The kits will be available at relevant centers and locations and will be used by trained personnel.

- Sand layers as filters in seepage pits (detritus basins in the form of a shallow pit connected to drain trenches) would be used, allowing hardly any harmful substance to percolate into deeper soil layers or into the groundwater.
- Inspection and maintenance of permanent erosion and runoff control features will be done regularly.
- Oil separators will be installed at fuel stations.
- Facilities designed according to the maximum number of people at the operational sites will be used, and the reuse of the effluent or its connection to the city sewer network will be planned.
- Motorway will be paved in dry weather to prevent runoff of asphalt or cement materials.
- In need of deicing, mechanical deicing methods (sweepers and plows) will be used at first. It will be complemented by chemical means if necessary. In addition to that, anti-icing and deicing agents will be selectively applied based on expected pavement temperatures and the use of road weather information systems. Furthermore, employees applying anti-icing and deicing agents will be trained to use these at optimum rates and times. Anti-icing and deicing agents will be selected based on the potential environmental impacts of the particular agent.

VIII.4.3.2. Mitigation Measures for Groundwater Flow Regime

- Measures will be developed to ensure that no indirect impacts on any important groundwater resource take place. Where medium to long-term or permanent dewatering is required, the water would not be drained to the Motorway drainage system but to a near surface water course.
- Infiltration will be promoted if water depletion arises in areas of groundwater wells to ensure the supply, especially in urban settings.

VIII.5. Summary of Assessment and Residual Impacts

Table VIII.14 provides a summary on water resources assessment. The significance of the identified impacts before and after the implementation of mitigation measures are summarized in this table. With proper implementation of good water management practices, water pollution risks would not cause any significant impact on the ecosystem or bring associated risks on the health and safety of the community and/or Project personnel.

Table VIII.14 Summary of the Assessments on Water Resources

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude

Adverse	Local	Short	Low	Irreversible	One-off	Modarate (B)	Low (1)	Low (B1)	● Stormwater management practices that slow peak runoff flow, reduce sediment load and increase infiltration; including vegetated swales (planted with salt-resistant vegetation), filter strips, terracing, detention ponds or basins, and infiltration trenches will be planned.	Low

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Operation Phase												
Contamination of surface waters with de-icing material	Surface Water	Adverse	Local	Short	Low	Short-term reversible	Intermittent	Minor (C)	Low (1)	Low (C1)	● In need of deicing, mechanical deicing methods (sweepers and plows) will be used firstly, it will be complemented by chemical means if necessary. In addition to that, anti-icing and deicing agents will be selectively applied based on expected pavement temperatures and the use of road weather information systems. Furthermore, employees in the application of anti-icing and deicing agents will be trained to use these at optimum rates and times. Anti-icing and deicing agents will be selected based on the potential environmental impacts of the particular agent.	Low
Contamination of surface waters with hazardous materials due to spills from stations		Adverse	Local	Short	Medium	Short-term reversible	One-off	Minor (C)	High (3)	Medium (B2)	● Sealed basement and bunds with a capacity of the 100% of the storage capacity of the largest tank will be used at fuel stores and other harmful substance stores. ● For case of any large scale spill, absorbent materials within spill response kits will be used. They kits will be available at relevant centers and locations and will be used by trained personnel. ● Sand layers as filters in seepage pits (detritus basins in the form of a shallow pit connected to drain trenches) would be used allowing hardly any harmful substance to percolate into deeper soil layers or into the groundwater. ● Oil separators will be installed at fuel stations.	Low
Contamination of surface waters due to dumped waste from vehicles		Adverse	Local	Long	Medium	Long-term reversible	Continuous	Modarate (B)	Low (1)	Low (B1)	● In order to provide direct run-off to the collection system; channels, bunds and sandbag barriers will be used.	Low
Contamination of surface waters due to wastewater discharge.		Adverse	Local	Long	Medium	Long-Time reversible	One-off	Modarate (B)	High (3)	High (B3)	● Package treatment plants designed according to the maximum visitor capacity anticipated for the highway service areas will be used. ● Package treatment plants will be used for facilities with continuous operations.	
Increase on the rate of surface water runoff and high storm water flow rates can lead erosion and flooding		Adverse	Wide	Long	Moderate	Long-Time reversible	Continuous	Major (A)	High (3)	High (A3)	● In order to limit the volume of water requiring specialized treatment (during land preparation and construction, and operation phases) segregation of liquid effluents, principally along industrial, sanitary and stormwater categories, will be planned. ● All wastewater discharges from all components of construction must comply with relevant legal requirements. Treated water will be reused where possible and feasible.	Low

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Contamination of groundwater by possible contaminated runoff from road pavement	Groundwater	Adverse	Local	Short	Low	Irreversible	One-off	Modarate (B)	High (3)	High (B3)	● Measures will be developed to ensure that no indirect impacts on any important groundwater resource take place. Where medium to long-term or permanent dewatering is required, the water would not be drained to the Motorway drainage system but to a near surface water course. ● Project elements will be located to minimize risks on groundwater. Groundwater use for project activities would be planned to be limited and would be done only after getting relevant permissions from the authorities.	Low
Contamination of groundwater resources with hazardous substances due to accidents and leakages		Adverse	Local	Short	Medium	Irreversible	One-off	Modarate (B)	High (3)	High (B3)	● Hazardous materials will not be stored within excavated areas. Supervision will be used during handling of all hazardous materials. Impervious bunds and other containment techniques will be used where hazardous materials are handled.	Low
Infiltration of surface water run-off to groundwater		Adverse	Local	Short	Low	Irreversible	One-off	Modarate (B)	Low (1)	Low (B1)	● Stormwater management practices that slow peak runoff flow, reduce sediment load and increase infiltration; including vegetated swales (planted with salt-resistant vegetation), filter strips, terracing, detention ponds or basins, and infiltration trenches will be planned.	Low
Contamination of ground water due to wastewater discharge.		Adverse	Local	Long	Medium	Long-Time reversible	One-off	Modarate (B)	High (3)	High (B3)	● The water exiting the wastewater treatment plants will first be planned for reuse, and if discharge is necessary, it will be connected to the city sewerage system.	
Decrease of groundwater recharge due to expending impermeable surface area		Adverse	Local	Long	Low	Irreversible	Continuous	Moderate (B)	Low (1)	Low (B1)	● Infiltration will be promoted if water depletion will arise in areas of groundwater wells to ensure the supply, especially in urban settings.	Low

IX. ECOLOGY AND BIODIVERSITY

This chapter of the ESIA report describes the ecological characteristics of the Antalya-Alanya Motorway Project Area. Furthermore, it identifies the potential impacts on the biological environment arising from the Project activities.

In the scope of the biological studies for the Antalya-Alanya Motorway Project, biological environment studies that included terrestrial flora and fauna, aquatic flora and fauna, and protected areas have been conducted with desktop studies and field surveys, which are described in detail in the following sections. The assessment follows the recommendations and requirements of the IFC Performance Standard 6 (PS6): Biodiversity Conservation and Sustainable Management of Living Natural Resources.

Biological environment field studies conducted in July 6-22 2024 in the summer, September 28 – October 12 2024 in the autumn, January 10-29 2025 in the winter and February 28 – March 31 2025 in the spring. Within these field studies, terrestrial and aquatic flora-fauna studies were carried out at the selected sampling points. The team members that conducted the field study are listed below.

Table IX.1. Biodiversity Field Study Team Members

Name	Profession	Occupation
Prof. Erdoğan Çiçek	Hydrobiologist / Ecologist	Prof. at Nevşehir Hacı Bektaş Veli University
Prof. Ferhat Celep	Botanist	Prof. at Kırıkkale University
Dr. Medine Münevver Koçum	Botanist	Hana R&D and Consulting Ltd. Co.
Assoc. Prof. Hakan Karaardıç	Zoologist / Ornithologist	Assoc. Prof. at Alanya Alaaddin Keykubat University
Assoc. Prof. Yasin Ünal	Zoologist / Mammalogist	Assoc. Prof. at Isparta University of Applied Sciences
Assoc. Prof. Sevil Sungur	Zoologist / Hydrobiologist	Assoc. Prof. at Nevşehir Hacı Bektaş Veli University
Assist. Prof. Mert Karış	Zoologist / Herpetologist	Assist. Prof. at Nevşehir Hacı Bektaş Veli University
Expert Biologist Mehmet Gül	Biodiversity Expert	Biocon Environmental and Ecological Consulting
Assoc. Prof. Kubilay Toyran	Mammalogist	Biocon Environmental and Ecological Consulting

To evaluate the Project's potential impacts on the biological environment and various species inhabiting natural habitats within and around the Project Area, terrestrial and aquatic ecosystems were studied to identify the existing biological conditions. As a result, the Ecology and Biodiversity Chapter was prepared in accordance with two main lines of studies as terrestrial and aquatic on the biological environment.

IX.1. Baseline Data Collection

A study area is defined within a 400 m buffer along the length of the route for terrestrial studies. In the scope of the terrestrial field studies, sampling points representing different habitat types and natural and/or sensitive areas chosen by analyzing appropriate satellite imagery, and field surveys were carried out within and in the vicinity of those sampling points (see Figure IX.1 and Figure IX.2). Within the context of aquatic studies, rivers crossing on the motorway route and some streams were

chosen according to importance by hydrobiology experts. General information about methodologies is described in the following topics.

Within the scope of the field studies, a review of existing information was undertaken, and the ecological composition of the Motorway routes in terms of terrestrial and aquatic flora and fauna elements, potential sensitive areas, and critical species were identified.

The information gathered included information on:

- Internationally Recognized Areas (KBAs, IBAs, RAMSAR sites)
- Biological components of terrestrial environment
    - Terrestrial flora and ecosystems
        - Vegetation and habitats
    - Terrestrial fauna components
        - Amphibians and reptiles
        - Birds
        - Mammals
- Biological components of aquatic environment

IX.2. Legal Framework and Reference Standards

The observation and sampling locations are identified based on the previous knowledge regarding the area, expert's opinion and the available maps, images and information in hand. The aim of the data review was to collect existing baseline information on ecological receptors potentially present in the study areas (including designated sites, habitats and species). This was then used to inform the scope and design of the detailed methodologies for the field survey work. The data review also provided contextual information about the status of ecological receptors (e.g. local, regional and global distribution, population size and level of extinction risk) and ecological information about the receptors (e.g. habitat requirements and behaviour of species) to assist with the valuation and assessment of potential impacts. The data review included an extensive review of published scientific literature, websites and other sources.

The ecology assessment has considered relevant Turkish (national) legislation, applicable standards and guidelines for international finance, and international agreements to which Türkiye is a signatory. Applicable policy and legislation relevant to the ESIA are presented in Chapter 2 ("Institutional and Legal Framework") with those of particular relevance to ecology summarized below.

Internationally accepted criteria are considered while choosing sampling points in the study area together with the species characteristic and habitat needs. This were done by overlaying the Project Area with the distribution of species of conservation concern; with sites identified as globally important for migratory species (e.g. IBAs, RAMSAR sites); with national parks, protected areas, and key biodiversity areas.

IX.2.1. International Agreements

In evaluating the threat/protection status of species; CITES (Convention on International Trade in Endangered Species of Wild Fauna and Flora), Bern Convention, and IUCN (International Union for Conservation of Nature) Red List Database were used. Additionally, hunting status of all fauna

elements was determined according to 2024-2025 Decision of the Central Hunting Commission (CHC) of Türkiye.
Species covered in CITES are given under three different appendices according to their conservation status. Appendix I cover the species, which are under the threat of extinction. Trade in the specimens of these species is not allowed except extraordinary circumstances. Appendix II includes species, which are not threatened with extinction, but trade in specimens is restricted in order to prevent utilization incompatible with their survival. Appendix III includes species, for which other parties of CITES is applied for assistance in controlling trade and which are conserved at least in one country.

Convention on Wetlands of International Importance, especially as Waterfowl Habitat (Ramsar Convention) provides a framework for national action and international cooperation for the conservation and wise use of wetlands and their resources. Türkiye became a contracting party in 1994.

BERN Convention aims at conserving and promoting biodiversity, developing national policies for the conservation of wild flora and fauna and their natural habitats, protection of the wild flora and fauna from the planned development and pollution, developing trainings for protection practices, promoting and coordinating the research made regarding this subject. It has been signed by 26 member states of the European Council (as well as Türkiye) with the aim of conserving the wildlife in Europe. Species that are protected under the Bern Convention are classified according to the following categories:

- Appendix I: Strictly protected flora species.
- Appendix II: Strictly protected fauna species.
- Appendix III: Protected fauna species.

All the nations, which are party to the BERN Convention, have signed the Convention on Biological Diversity as well. These parties are responsible from ensuring sustainable use of resources in line with their national development trends and conserving threatened species.
To determine the threatening status of species IUCN classifications are also used, which are used in Turkish classification as well. IUCN Red List is published to highlight those species that are facing a risk of extinction. A species may be listed in IUCN Red List after studies on its population decrease. Thus, since IUCN List is based on research (annual updates are being made for species lists of countries), many countries attach more importance to species taking place in IUCN list than species taking place in Bern List.

The IUCN categories were updated in 2001 as ver. 3.1 (previous one was 1994 as ver. 2.3) and are provided below:

Table IX.2. International Union for Conservation of Nature (IUCN) Categories

IUCN Red List Categories and Criteria, 1994 (ver. 2.3)		IUCN Red List Categories and Criteria, 2001 (ver. 3.1)	
EX	: Extinct	**X**	: Extinct
EW	: Extinct in Wild	**EW**	: Extinct in Wild
CR	: Critically Endangered	**CR**	: Critically Endangered
EN	: Endangered	**EN**	: Endangered
VU	: Vulnerable	**VU**	: Vulnerable
LR	: Low Risk		
	cd : conservation dependent	**NT**	: Near Threatened
	nt : near threatened	**LC**	: Least Concern
	lc : least concern		
DD	: Data Deficient	**DD**	: Data Deficient
NE	: Not Evaluated	**NE**	: Not Evaluated

As an environmental treaty of the United Nations, CMS provides a global platform for conserving and sustainable use of migratory animals and their habitats. CMS brings together the States through which migratory animals pass, the Range States, and lays the legal foundation for internationally coordinated conservation measures throughout a migratory range.
As the only global convention specializing in the conservation of migratory species, their habitats, and migration routes, CMS complements and co-operates with a number of other international organizations, NGOs, and partners in the media as well as in the corporate sector.

Migratory species threatened with extinction are listed in Appendix I of the Convention. CMS Parties strive to strictly protect these animals, conserve or restore the places where they live, mitigate obstacles to migration, and control other factors that might endanger them. Besides establishing obligations for each State joining the Convention, CMS promotes concerted action among the Range States of many of these species.

Migratory species that need or would significantly benefit from international cooperation are listed in Appendix II of the Convention. For this reason, the Convention encourages the Range States to conclude global or regional agreements.

IX.2.2. Turkish Legal Requirements

It is the responsibility of the Ministry of Agriculture and Forestry (MoAF), together with the MoEUCC and their affiliated organizations to formulate policies concerning the conservation of biodiversity in Türkiye designate and manage protected areas, to develop and implement plans and programmes, to carry out activities in this scope and to provide coordination among all relevant institutions.

The affiliated organizations of the MoAF are the Special Environmental Protection Agency, the General Directorate of Forestry, the General Directorate of the State Meteorological Service, and the General Directorate of State Hydraulic Works. The provincial organization of the MoAF consists of the Provincial Directorates of Agriculture and Forestry, as well as the regional directorates of the affiliated organizations.

The MoAF's unit with primary authority and responsibility for the conservation and sustainable use of biological diversity is the General Directorate of Nature Conservation and National Parks, which is also the CBD focal point. The General Directorate of Nature Conservation and National Parks is the principal unit responsible for the management of protected areas designated under the National Parks Law, for the conservation of wildlife and for the regulation and supervision of terrestrial hunting.

The Central Hunting Commission (CHC) is established under the Terrestrial Hunting Law and includes members from MoAF and General Directorate of Nature Conservation and National Parks, Directorate of Hunting and Wildlife, universities, Ministry of Food, Agriculture and Livestock, non-governmental organizations, hunting associations and Gendarmerie General Command. CHC prepares a resolution every year and this resolution is published in the official gazette. The recent resolution covers the hunting season for 2024-2025. These resolutions define hunting periods, limits (in terms of number of individuals that can be hunted and dates for hunting), areas where hunting is banned, as well as the species that can and cannot be hunted. Thus, CHC resolutions provide some measure of regulation over the exploitation of wildlife within Türkiye. In this regard, according to 2024 and 2025 Resolutions of the CHC appendixes are as follows:

- Appendix I; Includes game animals which are protected by the CHC.
- Appendix II; Includes game animals which are allowed to be hunted in seasons predefined by CHC.

The legislations listed in Chapter 2, provide some areas protection status based on the presence of significant biological diversity, local endemics of importance, and threatened species. These designations include Natural Protected Sites, National Parks, Nature Protection Areas, Wildlife Protection and Development Sites and Specially Protected Areas.

Activities in such designated areas are also covered various regulations, but these areas are not specifically provided a protection status. In Türkiye, there is no conservation status for habitats as defined by a specific vegetation as there is provided in European Union (EU) countries where the EU Habitats Directive applies. In Türkiye, there is no specific habitat compensation requirement. There is only a policy regarding forested areas, which aims to replant at least as much of the forest area that is lost due to development activities.

There are also laws and regulations that are in effect to protect other environmental components, as well as to minimize pollution, promote sustainable development and management of natural resources. Legislation relating to air quality, environmental management and permitting, health and safety, management of chemicals and other dangerous substances, noise, soil quality, water quality and waste management, also provide management of issues that might have secondary impacts on biodiversity components. Environmental laws and regulations that do not primarily relate to ecology will be referenced in the relevant chapters of the ESIA.

In addition some national to the public were used for to collect existing baseline information. Birds of the study area were assessed according to national threat categories defined in the Red Data Book of Birds of Türkiye (Kiziroglu, 2009) according to the categories defined in Table IX.3.

Table IX.3. National Threat Categories for Bird Species

Category A		
A.1.2	(CR)	Critically endangered and breeding species in Türkiye
A.2	(EN)	Endangered and breeding species in Türkiye
A.3	(VU)	Vulnerable and breeding species in Türkiye
A.3.1	(D)	Declining, vulnerable and breeding species in Türkiye
A.4	(NT)	Near Threatened, breeding species not facing risk now, but are likely to qualify for threatened category in the near future in Türkiye
A.5	(LC)	Least Concern, breeding species that are widespread in Türkiye
A.6	(DD)	Data Deficient, breeding species on which there is deficient information in Türkiye
A.7	(NE)	Not evaluated, breeding species which have not been evaluated in Türkiye
Category B		
B.1.2	(CR)	Critically endangered and non-breeding species in Türkiye
B.2	(EN)	Endangered and non-breeding species in Türkiye
B.3	(VU)	Vulnerable and non-breeding species in Türkiye
B.3.1	(D)	Declining, vulnerable and non-breeding species in Türkiye
B.4	(NT)	Near Threatened, non-breeding species not facing risk now, but are likely to qualify for threatened category in the near future in Türkiye
B.5	(LC)	Least Concern, non-breeding species that are widespread in Türkiye
B.6	(DD)	Data Deficient, non-breeding species on which there is deficient information in Türkiye
B.7	(NE)	Not Evaluated, non-breeding species which have not been evaluated in Türkiye

In determining threat statuses of flora species identified within the study area Red Data Book for Turkish Plants (Ekim et al., 2000), which was prepared in accordance with 1994 IUCN Red List Categories and Criteria was utilized, and the evaluations will be presented in the Annex-10 of the ESIA Report.

Law No. 3573 on Olive Cultivation and Grafting of Wild Species provides protection for olive groves in Türkiye. It defines olive-growing areas broadly and prohibits cutting or removing olive trees without official approval. The law also restricts industrial facilities within 3 km of olive groves to preserve agricultural and environmental values.

IX.2.3. Standards and Guidelines for International Requirements

The Project is committed to implementing the IFC Performance Standards (PS) in order to manage social and environmental risks and impacts. IFC PS6 covers areas of biodiversity conservation, ecosystem services and sustainable management of living resources, which are all fundamental to achieve sustainable development. The objectives of PS6 are outlined as follows:

- To protect and conserve biodiversity.
- To maintain the benefits from ecosystem services; and

- To promote the sustainable management of living natural resources through the adoption of practices that integrates conservation needs and development priorities.

The requirements of PS6 are applied to projects:

i. Located in modified, natural, and critical habitats;
ii. that potentially impact on or are dependent on ecosystem services over which the client has direct management control or significant influence;
iii. or that includes the production of living natural resources (e.g. agriculture, animal husbandry, fisheries and forestry) based on the risks and impacts identification process.

Ecosystem Services Review (ESR)

Ecosystem Services Review (ESR) was prepared in relation to the IFC Biodiversity Conservation and Sustainable Management of Living Natural Resources Guidance Note 6 requirements to determine ecosystem services to The Project.

Biodiversity and ecosystems are closely related concepts. Biodiversity is defined by the Convention on Biological Diversity as “the variability among living organisms from all sources including, inter alia, terrestrial, marine and other aquatic ecosystems and the ecological complexes of which they are part; this includes diversity within species, between species and of ecosystems” (United Nations 1992:Article 2). Ecosystem Services (ES) which are the goods provided by ecosystems upon are the benefits that people obtain from ecosystems (MA 2003). For example, a stand of trees can reduce air pollution, purify the water supply, reduce the likelihood of floods and help regulate the climate by capturing and storing carbon. It might also provide timber for buildings, a space for recreation and improve the aesthetic qualities of the landscape.

The environment provides mankind with the food, water and air that are essential for life and with the minerals and raw materials for industry and consumption. Less obviously, it provides the processes that purify air and water, and which sequester or break down wastes. These services that the environment provides as all ecosystem services which require the existence of living organisms for their delivery, but in many cases it is not the diversity of the organisms that is important, but the presence of a viable population of at least one species representing a particular functional group and the delivery of many ecosystem services requires a non-trivial amount of biodiversity, but not necessarily the maximum amount possible in that environment. Also recreation and health are found in which human culture finds its roots and sense of place are included in ecosystem services. Taking into consideration overall ecosystem services are the many different benefits that ecosystems provide to people (MA, 2005). Therefore, both ecological and socio-economic studies support to identification ecosystem services of Motorway Project Area in the line with IFC Performance Standards and the initial literature studies.

The overall aim of the ecosystem service concept is to bring a holistic approach to environmental decision-making by valuing the environment in terms of the benefits people obtain from ecosystems. It is practical and pragmatic, focusing on goals that provide greatest environmental benefit at least cost to society and the natural environment with the aim of avoiding taking decisions with unintended secondary consequences that may be costly, increase risk or be detrimental to ecosystems and human well-being. The evaluation of the effects, both desirable and undesirable, of approaches to landscape management on the delivery of ecosystem services allow for a broader assessment of the true costs and benefits of actions and policies.

Ecosystem service principles and/or cost-benefit analyses are enshrined in European environmental protection legislation and policies such as the Environmental Liability Directive (2004/35/EC), the Habitats Directive (92/43/EEC), the Water Framework Directive (2000/60/EC) and the REACH Directive (1907/2006). Recent initiatives such as the United Nations Millennium Ecosystem Assessment (2004), UK National Ecosystem Assessment (2011) and The Economics of Ecosystems and Biodiversity (TEEB, 2010) have built on concepts and methods developed over more than 20 years in the United States to deal with legacy contamination (US Natural Resource Damage Act). Many of the US approaches have informed more recent European initiatives on environmental liability, habitat banking, biodiversity offsetting, life cycle assessment (foot printing), strategic planning, operational risk reduction and now product registration. ES are depicted within four service subset categories as follows:

- Provisioning Services are ecosystem services that describe the material or energy outputs from ecosystems. They include food, water and other resources.
- Regulating Services are the services that ecosystems provide by acting as regulators e.g. regulating the quality of air and soil or by providing flood and disease control.
- Cultural, Spiritual, and Recreational Services are provide that benefits which are non-material obtains include recreational facilities and tourism, aesthetic appreciation, inspiration, a sense of place, and educational value.
- Supporting Services are necessary for the production of all other ecosystem services such as soil formation nutrient cycling and primary production. They differ from provisioning, regulating, and cultural services in that their impacts on people are either indirect or occur over a very long time, whereas changes in the other categories have relatively direct and short-term impacts on people.

In addition, when the projects may affect ecosystem services of relevance to local people, Affected Communities attached to biodiversity and ecosystem services will participate in the determination of priority ecosystem services in accordance with the stakeholder engagement process which is one of the key means to understanding impacts on biodiversity and identifying appropriate responses to such impacts as defined in IFC Performance Standard.

The IFC Performance Standards which is in line with the definition provided by the Millennium Ecosystem Assessment are covered divide Ecosystem services into two priority types:

Priority 1: Provisioning, regulating, cultural and supporting ecosystem services, over which the client has direct management control or significant influence, and where impacts on such services may adversely affect communities.

Priority 2: Provisioning, regulating, cultural and supporting ecosystem services, over which the client has direct management control or significant influence, and on which the Project directly depends for its operations.

Within the scope of the Motorway Project, the ecosystem services that are relevant to the Project AoI and categories them according to either priority 1 or priority 2 are summarized in “9.8. Ecosystem Services” section.

IX.3. Ecological Baseline Research

Ecological studies related to the Motorway were carried out in collaboration with subject-matter experts, covering both terrestrial and aquatic environments. As a result, the biological environment field study was carried out 06-22 July 2024 in the summer, 28 September-12 October 2024 in the autumn, 10-29 January 2025 in the winter and February 28 – March 31 2025 in the spring. These field studies carried out terrestrial and aquatic flora-fauna studies at the selected sampling points.

An additional Bat survey has been conducted as a pre-construction survey on August 21-22-23 2025 for day and night surveys. This survey and its finding have been added to this ESIA.

All ecological research was conducted with desk-based and field studies to determine the baseline conditions in the study area. These baseline data/information collections were provided with an overall picture of the conditions and sensitivities in the area that will be considered in the assessment of potential impacts and the development of relevant mitigation measures for design.

For terrestrial environment studies, it is not practical to survey the entire route. Therefore, the locations chosen by experts were visited by survey team according to the representativeness of each habitat type within the study area. These locations are named as sampling points. These sampling points can be revised according to the result of the field surveys observations. Sampling points were chosen to ensure that each habitat type displayed in the European Nature Information System (EUNIS) habitat classification was visited. All of the different habitats were ground-truthed in the study area.

During the flora and fauna studies, surveys were conducted along nine distinct transect lines based on habitats and vegetation composition. Observations were carried out along each line, with adjustments made based on changes in habitat characteristics.

Bird surveys were conducted over a period of 30 days each during the autumn migration period of 2024 (August–November) and the spring migration period of 2025 (March–June). Bird survey activities have been completed in June 6^{th,} 2025. Surveys were carried out along nine transect lines, in addition to point count surveys. Furthermore, data from the bird ringing studies conducted during both migration periods at the Boğazkent Bird Ringing Station were incorporated into the assessment.

A sound recording device (Batcorder) was used for bat surveys. Based on interviews conducted with the local village governance, the device was installed on trees near buildings used as barns in six pre-determined villages. In each village, the Batcorder recorded continuously for a minimum of 24 hours before being retrieved. Bat monitoring studies were also conducted in the area designated as 7. Karakaya TO. As part of these studies, rocky areas were surveyed to identify potential bat nesting and roosting sites. Although no cave formations were detected, wide cracks and fissures were observed within the rock structures. A Batcorder device was deployed in this area for duration of seven days. Additionaly pre-construction surveys have been carried out in 2 bat survey locations (between KM104+000 – 105+000) identified within the scope of baseline surveys conducted before.

Additionally, aquatic studies that cover both desk-based and field studies to determine the baseline conditions in the study area were conducted. River crossings with the well-conditioned flow during the field studies along the motorway route were determined and studied according to suitable methodologies during the aquatic field surveys.

The overall approach to determine the baseline conditions in the context and objectives provide above included the following data collection and interpretation means:

- Review of pertinent literature and previous works,
- Field studies carried out in the Project Area,
- Satellite image interpretation, as available,

- Communication with the inhabitants in the study area during the field studies,
- Consultation with nature conservation administration and related agencies and institutions concerned.

In the scope of the ESIA report, based on the assessed impacts, significant relevant measures for mitigating adverse impacts were developed. The importance/sensitivity of the habitats and species were given special attention in reporting, and detailed data such as identified species list, their habitats, endemism, and protection status were included.

IX.3.1. Definition of the Study Area and Area of Influence

The study area definition was made for both terrestrial and aquatic environments. In this context for terrestrial environment studies, the survey encompassed as much of the habitat along the proposed Motorway route and facility areas used in the scope of the Project as access and topography allowed. Thus, at each sampling point and their vicinity, the features of the landscape and environment include the dominant habitats and species of note. In addition, 200 m buffers on either side of the route were used to guide the habitat survey to ensure a suitable habitat sample was covered. “Study area” is defined as a 400 m buffer zone.

In addition to investigations conducted within the project corridor, field studies were also carried out in the expropriation corridor of the Project. These components include:

- Quarry and fill areas
- Temporary construction sites, campsites, and material storage zones
- Soil dumping sites and landfill areas
- Service roads and temporary transportation routes

Furthermore, faunal monitoring activities extended beyond the stations with predefined coordinates. These studies aimed to assess the potential presence of species anticipated from literature and site survey data but not previously observed within the main project corridor or designated side areas.

For instance, to assess the distribution range of *Lyciasalamandra atifi*—a species endemic to the region—targeted field investigations were conducted in the suitable habitats for the species approximately 5 kilometers north of the proposed motorway alignment.

400 m buffer along the length of the route for terrestrial studies, there are 36 sampling locations for fauna and flora studies and 14 for the aquatic environment according to different habitat types (see Table IX.4). The observation points which batcorder device used was for bat surveys are given in Table IX.5.

In the scope of the Project terrestrial and aquatic environment site, surveys were carried out in vegetation periods by experts. As a result, terrestrial and aquatic flora-fauna observation and sampling points and transect lines are given in Figure IX.1,Figure IX.2,
Figure IX.3,
Figure IX.4,
Figure IX.**5**, Figure IX.6, Figure IX.7. Studies were also carried out at wider project components such as storage areas Table IX.6, quarries and borrow pits Table IX.7.

The Project's Biodiversity Area of Influence (AoI) is defined as the geographic area where the Project's direct, indirect, and cumulative impacts on biodiversity and ecosystem services are reasonably expected to occur. This includes the direct footprint of the motorway, incorporating carriageways, interchanges, viaducts, tunnels, and associated infrastructure, where permanent land take and habitat conversion will occur. It also includes a zone of influence beyond the footprint where indirect impacts may arise, such as habitat fragmentation, edge effects, species disturbance, alteration of surface water and groundwater regimes, and increased accessibility to previously undisturbed areas.

Temporary facilities such as construction camps, borrow pits, spoil disposal areas, and access roads are considered part of the AoI due to their potential to generate short- and medium-term impacts on habitats and species. Therefore for terrestrial and aquatic habitats, flora, mammals, herpetofauna and birds a 400m buffer zone was identified as a study area (not including transect locations) and a 2 km perimeter was decided around each project component designated as AoI. As transect locations, at some points the study area was extended as seen necessary (e.g. 5 km for Transect 15 and 2.5 km for D-7 storage area). The map for Area of Influence is given in Figure IX.8.

The overall corridor of the Antalya–Alanya Highway was defined by the General Directorate of Highways (KGM) prior to the Project Company's involvement. Within this fixed corridor, the Project design was further refined by the Project Company and EPC to address local topographic, geotechnical, and environmental conditions.

This included the use of viaducts around the Köprüçay Basin Natural Protected Area to cross the riparian zone without in-channel works, as well as adjustments to the location of temporary facilities to avoid sensitive habitats where feasible. Two examples of such adjustments include:

Dikmen Borrow Pit (Km 83+000): Initially planned in the vicinity of the Manavgat Waterfall, this location was changed to avoid potential disturbance to the adjacent stream and riparian zone.

Storage Area D-23 (Km 110+820): The layout of this temporary area was refined to prevent habitat loss and disturbance to nearby forest and riverside ecosystems.

Within the fixed corridor, further route-level changes were screened but found not feasible given corridor restrictions and land acquisition implications.

In line with the IFC Performance Standards, the principle of avoidance will continue to guide the Project throughout all design and construction stages — not only during initial planning. Any future design modifications will be reviewed by the Project's biodiversity specialists, and where sensitive habitats are identified, the hierarchy of avoidance, minimisation and restoration will be applied. Avoidance will remain the preferred approach wherever technically and spatially feasible, with mitigation measures implemented only when avoidance cannot reasonably be achieved.

Figures regarding the locations of Dikmen Borrow Pit and Storage Area D-23 are given in Annex 11C of this ESIA report.

IX.3.2. Internationally Recognized Areas within the Region of the Project Area

Internationally Recognized Areas are located in the surroundings of the Project Area located in the provinces of Antalya, and Mersin. These areas include Key Biodiversity Areas (KBA), Important Bird Areas (IBA) and Important Plant Areas (IPA). KBAs are the most critical areas according to their characteristics in terms of supporting biological components. There are 33 internationally Recognized areas found, and there are no RAMSAR areas within or around the Project Area. The studies determined that a portion of Antalya Plains KBA and IBA is within the Project Area. The total area and the part remaining within the Project's Study Area of this KBA/IBA are given in Table IX.8.

Table IX.8. Internationally Recognized Areas within the Region of the Project Area

Internationally Recognized Areas	Total Area (ha)	within the Study Area (400 m corridor)	
		ha	%
Antalya Plains KBA, IBA	27,039	277	1.02

The Internationally Recognized Areas included in the provinces covered in the Project Area are shown in Figure IX.9. Distance of the regions from the Project Area and the provinces located are summarized in Table IX.10.

The Project also intersects with Belek Special Environmental Protected Area (SEPA) and Köprüçay Basin Natural Protected Area, which are nationally protected areas. The total area and the part remaining within the Project's Study Area of this SEPA are given in

Table IX.9 Nationally Recognized Areas within the Region of the Project Area

Nationally Protected Areas	Total Area (ha)	Within the Study Area (400 m corridor)	
		ha	%
Belek SEPA	11,320	140.06	1.25
Köprüçay Basin Natural Protected Area	4,019	47.44	1.18

Designation criteria of SEPAs are based on the relevant Biodiversity Protocols of the Barcelona Convention, Bern Convention, Ramsar Convention and the Convention of Biodiversity commitments for endangered species, etc.

Table IX.10. Distances of Internationally Recognized Areas from the Project Area

Internationally Recognized Areas	Province	Distance from the Project Area (km)

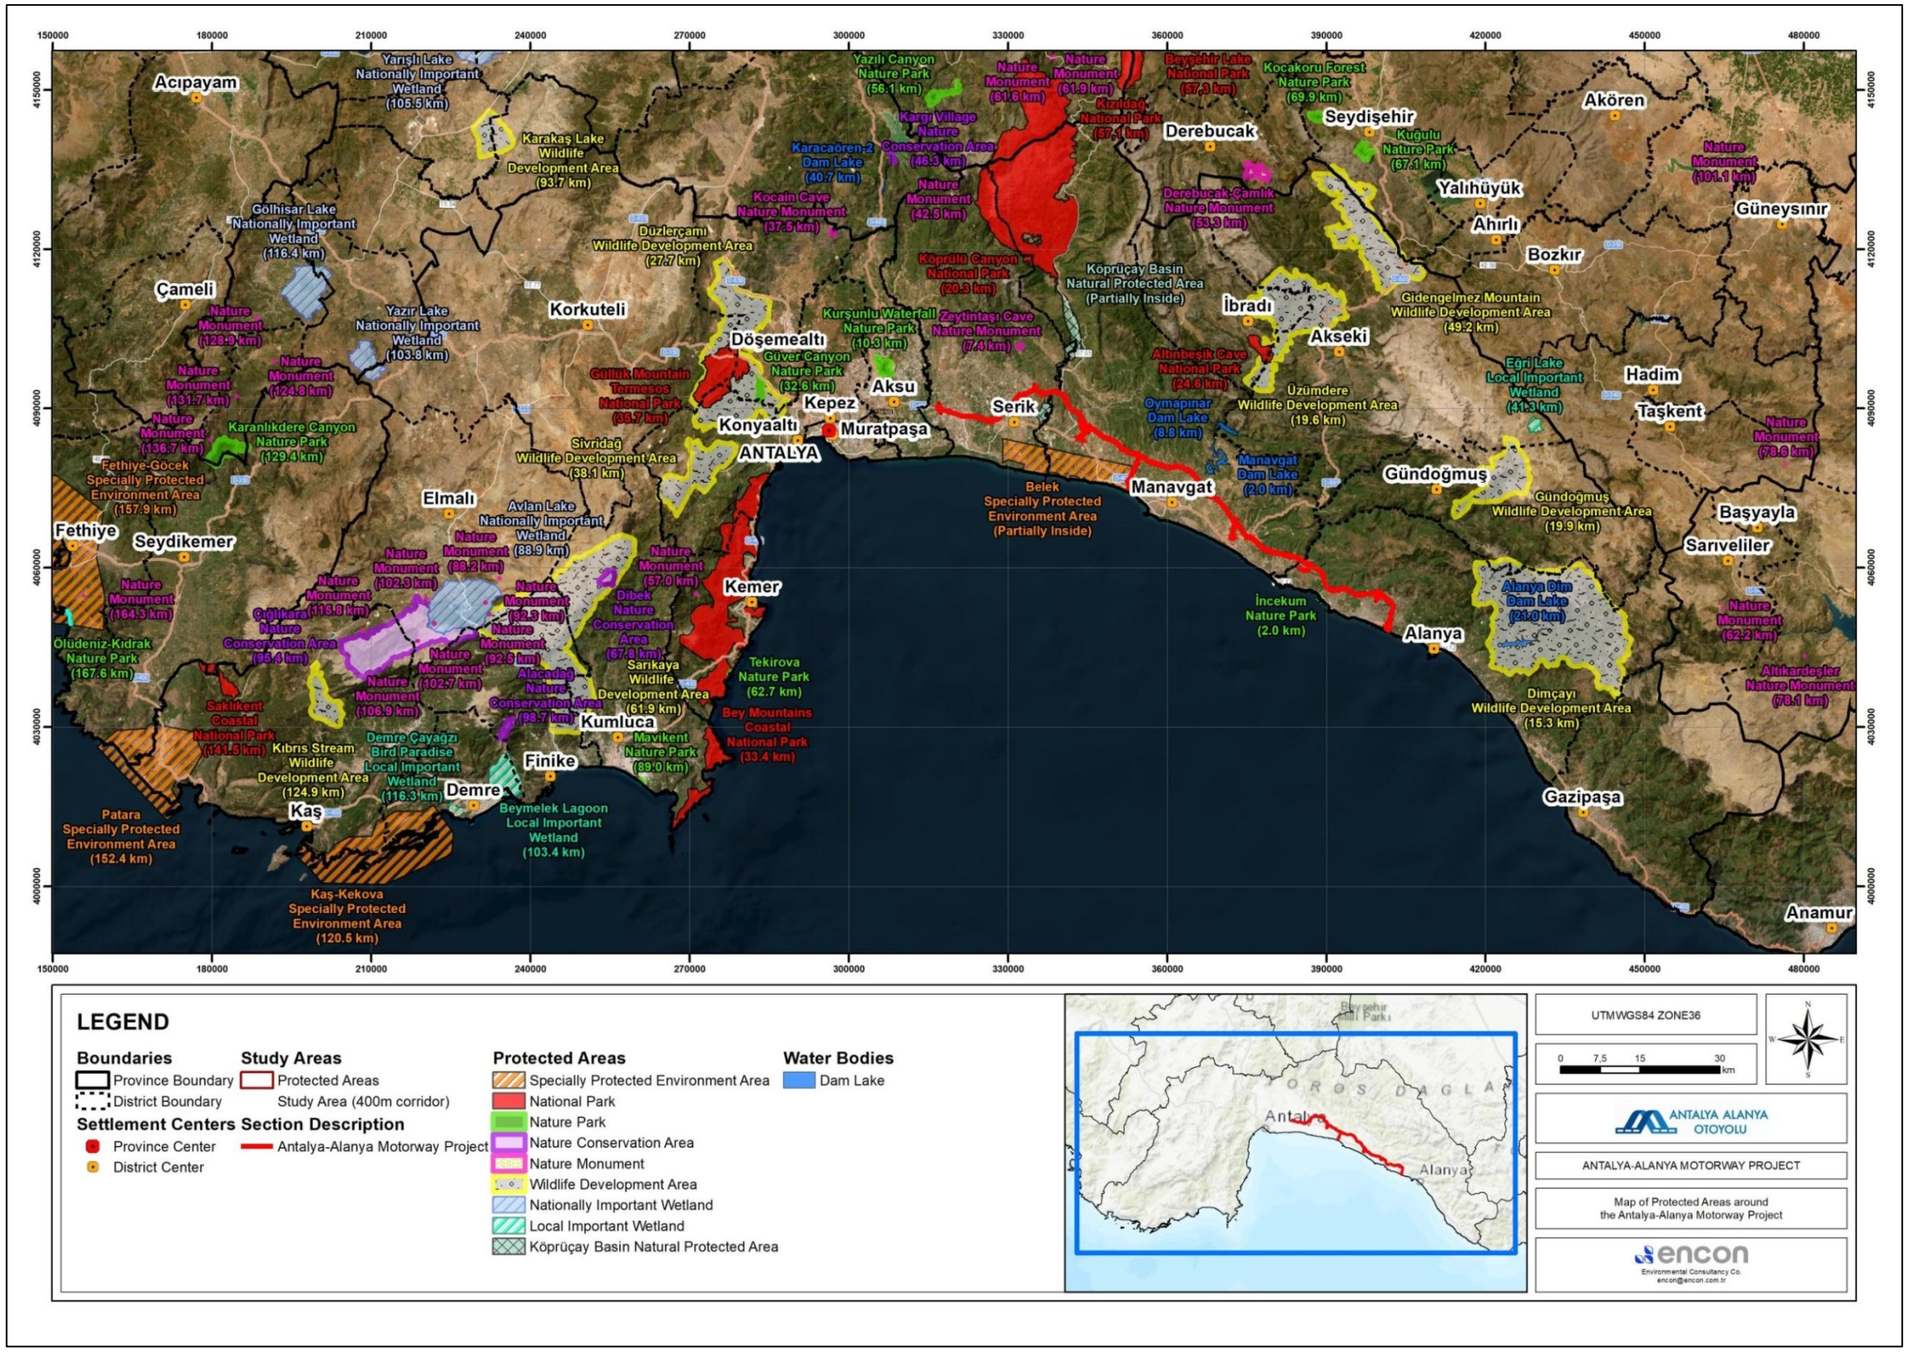

Figure IX.9. The Internationally Recognized Areas within the Region of the Project Area

IX.4. Methodology of Biodiversity Surveys

IX.4.1. Terrestrial Biodiversity

This section revealed terrestrial flora, fauna, ecosystem structures, and habitat features at the Motorway Project Area.

This baseline data/information collection provided an overall picture of the conditions and sensitivities in the area that were considered in assessing potential impacts and development of relevant mitigation measures for the design, construction, and operation phases of the Project. Terrestrial biodiversity studies investigated as following parts.

Population, ecology, and reproductive biology of the threatened and endemic flora-fauna species likely to occur within the study area of interest were studied. In addition, the literature survey was intended to give information on the identification of endemic, endangered, and rare species and species defined under the national and international conservation classes. Accordingly, species at risk of being affected due to the Project and, therefore, require special attention, and protection measures were determined.

The species identified during the field studies were recorded systematically to establish a species inventory for the baseline conditions and a description of the habitats. Also, endemic, protected, and restricted-range flora-fauna species were determined as the target species within the scope of the study. The most important area for these species is in natural habitats. The Project Area covers mostly plantation habitats and agricultural lands. Potential target species of each habitat were identified as a result of the literature review, and the identified target species were confirmed through field studies.

IX.4.1.1. Terrestrial Habitats and Flora Survey

Field surveys were carried out in order to determine the habitat and flora species present along the proposed route. Surveys were conducted for four seasons between 06-22 July 2024, 28 September-12 October 2024, 10-29 January 2025 in the winter and February 28 – March 31 2025 in the spring. Baseline surveys were conducted by Prof. Ferhat Celep and Dr. Medine Münevver Koçum.

Terrestrial habitats within the baseline study area are categorized as modified, natural, or critical habitats, according to IFC (2019). The definition of critical habitats depends on the presence of endemic, threatened, restricted-range species. As a result, distribution of the endemic, threatened, restricted-range species and EUNIS Level 3 habitat distribution within the Project Area were obtained.

The habitat classification follows the EUNIS habitat type classification. This comprehensive pan-European system facilitates the harmonized description and collection of data across Europe, including Türkiye, using habitat identification criteria. The preliminary habitat distribution in the study area is determined based on EUNIS Level 3 habitat type classification. A variety of habitat types were determined by analyzing appropriate satellite imagery and aerial photos (most of the territory of the Republic of Türkiye is covered by satellite imagery available through Google Earth). Since there are different habitat types within the study area, the European Nature Information System (EUNIS) habitat classification determines the number of different habitat types.

The habitats within the Motorway were determined with desktop studies according to EUNIS Habitat Classifications used satellite imagery. After the field studies, habitat types were verified and revised by expert observations.

Within the scope of the terrestrial flora studies, the flora and vegetation types within the study area were identified and served as a basis for determining the impacts of the Project on biological resources and developing appropriate mitigation measures, where necessary. In this context, floristic studies were conducted, including both desk-based and field studies, to determine the baseline conditions in the study area.
The objectives of the desktop study are to review and organize the existing information on terrestrial flora, habitats, and ecosystems within the study area. Therefore, potential species of conservation concern natural habitats and critical habitats present in the study area were determined before the field study and examined during field visits. As a result, terrestrial flora studies were carried out light on the following key baseline issues:

- To determine the flora species spreading on the Antalya-Alanya Motorway route,
- To identify habitat typesalong the route,
- Developing mitigation measures (in-situ and ex-situ) for rare, locally endemic or endangered species (CR, EN, and VU according to IUCN) that may be affected by construction and operation on the Antalya-Alanya Motorway route,
- If there are critical habitats in the Project Area, to provide habitat protection and development measures and suggestions so that these habitats will be affected by the project at least or not at all
- It is to identify the adverse effects that the project may have on the flora, develop mitigation measures to minimize these effects,
- To prepare a comprehensive flora report by IFC standards.

To determine the flora and vegetation structure on the Antalya-Alanya Motorway route, to determine if there are critically distributed plant species or habitats on the route, and to minimize the impact of the activity on these species and habitats, firstly, the number of sampling points to represent each habitat was determined on satellite images. The sampling points are planned to include both the areas representing the natural habitats on the route and the quarries where stone and gravel will be taken to be used in construction activities. Considering the effects that may occur on both sides of the road during the activity, 400 meter buffer zone was determined. Accordingly, 36 different sampling points and 19 transect lines representing different habitats were determined on the 117.8 km long motorway route. While determining the sampling points, priority was given to natural habitats and areas where critically distributed species were distributed.

Field studies were carried out in vegetation periods to study the stations determined on the route. The habitats determined during the field study were examined in detail, and the field notes were recorded in the field book. The habitat-based species in the floristic list were prepared based on the findings and observations obtained during the field trip.

Figure IX.10 Terrestrial Flora Field Studies

Floristic list; ferns (Pteridophyta), gymnosperms (Gymnospermae), and angiosperms (Angiospermae) are given, respectively. Families in each group are presented in phylogenetic order.

The plants collected from the Project Area were identified by "Flora of Türkiye and East Aegean Islands" (Davis, 1965-1985; Davis et al., 1988; Güner et al., 2000), Flora Europaea (Tutin et al., 1964-1980), Botanical Latin Basic sources such as (Stearn, 1966), Dictionary of Plant Science Terms (Altınayar, 1987) and Türkiye Plants List (Güner et al., 2012). In addition, sources such as Tubives (2022), Bizimbitkiler (2022), Euro+Med PlantBase (2022), ThePlantList (2022), The International Plant Names Index (2022), Kew (2022), GBIF (2022) were also used. The Turkish names of the detected plants were prepared using "Great Plants Guide" (Akalın, 1952), "Turkish Plant Names" (Baytop, 1997), "Plants in Anatolian Culture" (Akaydın et al., 2014) and "Our Natural Plants" (Akaydın, 2008). While determining the danger categories of endemic plants, the "Red Book of Plants of Türkiye" prepared by Prof. Tuna Ekim and his friends was used as the primary reference work, and these danger categories were reinterpreted considering the population of endemic species in the area and threat factors determined according to IUCN criteria.

In addition, in-situ and ex-situ protection measures related to locally or regionally distributed endemic, rare, or internationally protected species and critical habitats among the species identified in the project route are evaluated.

IX.4.1.2. Terrestrial Fauna Survey

Field surveys were conducted in order to determine the terrestrial fauna species present along the proposed route for four seasons between 06-22 July 2024, 28 September-12 October 2024, 10-29 January 2025 in the winter and February 28 – March 31 2025 in the spring. Baseline surveys were

conducted by Dr. Hakan Karaardıç (Ornithology expert), Dr. Yasin Ünal (Mammalogy expert) and Dr. Mert Karış (Herpetology expert).

The study areas were identified in collobration with flora expert and were located in the same positions as the flora survey areas in order to cover all habitat types along the proposed route.

The main objective of fauna studies is to identify the fauna elements (amphibians, reptiles, birds, mammals, and terrestrial invertebrates) of the study area, define the habitats these fauna elements inhabit and evaluate fauna and ecological characteristics of the study area. Terrestrial fauna field studies were conducted in a 400 m buffer which experts determined with desktop studies according to different habitat types. Twenty sampling points and 19 transect lines were based on during the site visits for fauna species. The expert have investigated and reported each fauna group as amphibian-reptiles, birds, and mammals during the terrestrial fauna field studies.

Besides these, objectives of the terrestrial fauna survey within the study area were described as follows;

- To determine the characteristics and importance of the Project Area in terms of terrestrial fauna species,
- To determine the critical and sensitive habitats and critical fauna species,
- To determine the protection status of the fauna species according to national and international conventions, decisions, and requirements.
- To determine potential impacts of motorway project on terrestrial fauna components.
- To determine mitigation measures to minimise offset- eliminate impacts on terrestrial fauna components.
- To determine the necessary measures to be taken to reduce the possible effects of the project activities (during construction and operation periods), especially on the breeding, migratory, and wintering fauna species, and to determine the faunistic monitoring study areas and times that will be carried out in the future periods,
- To determine the places/numbers of culverts that provide fauna passage.

In the Motorway route with the stated objectives, faunistic and ecological field studies were carried out.

- A total of 36 fauna study areas have been identified on the motorway line, representing different habitat types, suitable feeding, sheltering, and breeding areas for fauna species.
- In addition, habitats along the route, if any, in nearby areas that may be suitable for fauna were also included during the field studies.
- According to observation, literature, and habitat suitability, bird species were detected and included in the lists.
- “Line-transect method” was applied to determine fauna species and densities. In the study area, 400 m buffer were investigated.
- The presence of habitats suitable for the preferences of birds, traces of fauna (nests-cubs, feathers, footprints, vomit and feces, identifiable bone fragments), and feeding signs were also used to identify fauna species.
- Interviews and surveys were also conducted with the local people and the hunters in the region about the fauna elements in the study areas.
- In addition, the literature information obtained from the studies of this region in the past years was also used.

- In the species list tables, the systematic categories (Ordo - Familya) scientific names, Turkish - English names, threatened categories, and evaluations / recommendations of each species.
- Türkiye Vertebrates and Birds Red Lists (Ali Demirsoy - 2009-Kiziroglu 2009) and Central Hunting Commission Decisions 2021-2022 were used to determine the species' national hazard categories.
- The IUCN Red List, the Bern Convention, the CMS Convention, and CITES were used to determine the species' international hazard categories.
- It has been used in field studies advanced optical instruments (Binoculars and monocular telescopes) for avifauna and mammal observations and batcorder (bat sound recorder) device was used to record bat vocalizations. Additionally, camera traps have been used for mammal studies.

Figure IX.11 A Camera Trap Device Installed Within The Project Site

IX.4.1.3. Bat Surveys

Bat surveys were conducted using static detectors deployed for two nights between February 28 – March 31 2025. Survey locations chosen focused mainly around the quarries. These areas are located in the potentially important habitats for bats, due to the presence of caves and rocky formations.

A batcorder was used to record the bats' vocalizations in the survey locations. The vocalization data were analyzed to identify the potential species present within these habitats.

Additional bat surveys will be carried out in key habitats pre-construction to enhance understanding of bat species presence and distribution within the project area, and to ensure compliance with IFC Performance Standard 6 (PS6).

One pre-construction bat survey have already been carried out between August 21 2025, August 22 2025, and August 23 2025 for day and night surveys.

IX.4.2. Aquatic Environment

Field surveys were conducted in order to determine the terrestrial fauna species present along the proposed route for four seasons between 06-22 July 2024, 28 September-12 October 2024, 10-29 January 2025 in the winter and February 28 – March 31 2025 in the spring. Baseline surveys were conducted by Prof. Erdoğan Çiçek at 14 sampling points which were identified in correspondence of permanent or seasonal waterbodies crossed by the Project.

Within the scope of the Antalya-Alanya Motorway Project, the effects of the Project on the stream and river crossing areas on aquatic ecosystems were studied.

Fish species were evaluated within the scope of the monitoring since they are the indicator group that will be primarily affected by the motorway construction works. Investigations were made at 14 different stations where water was in the streambed based on the above. The availability, relative abundance, and conservation status of the fish caught were evaluated. In addition, the effects of the motorway transit points on the aquatic ecosystems and the precautions to be taken with the results were assessed.

The temporary or permanent streams along the motorway route will be crossed via bridges and viaducts. Since the bridge piers will be constructed on land, no intervention will be made in the riverbed. Therefore, it was not deemed necessary to plan a study on phytoplankton, zooplankton, and macrobenthic invertebrates in the aquatic ecosystem. A study was conducted on fish populations in the aquatic ecosystem within the Project Area.
During the construction of the Antalya-Alanya Motorway Project route, it may cause some effects on the aquatic ecosystem in the areas where aquatic ecosystem transitions will be made. It is important to know the reactions of aquatic organisms exposed to these effects and the precautions to be taken. For this purpose, aquatic organisms at the determined stations were examined, and the effects and precautions to be taken were given.

Accordingly, the following studies were carried out within the scope of aquatic studies:

- Habitat assessment of the aquatic stations where the motorway passes was made according to EUNIS.
- Sampling and laboratory studies were carried out for fish species from aquatic stations.
- National and international protection status and endemism status of the species were stated.
- The Project's effects on aquatic environments and the measures to be taken were defined.

IX.4.2.1. Aquatic Habitat Assessment

The assessment of habitat quality of the aquatic environment is based on the important physical characteristics of the water body and the surrounding terrains, particularly the catchment areas of the investigated site. All habitat parameters evaluated are related to aquatic life use and are a potential source of limitation of the aquatic environments.

The matrix used for assessing habitat quality of aquatic environments is based on the important physical characteristics of the water body and the surrounding terrain, particularly the catchment area of the investigated site. All habitat parameters evaluated are related to aquatic life use and are a potential source of limitation of the aquatic environment. The parameters used in habitat assessments mainly consist of epifauna substrate and its properties, velocity and depth conditions, sedimentation, stream bed width, occupancy conditions, riparian zone stability, and cover condition.

Sampling of Aquatic Organisms

Freshwater Fishes

Freshwater fishes were sampled using electrofisher and cast nets on the motorway axis to determine fish species in the Project Area (see
Figure IX.12). The captured specimens were placed in a bucket filled with water and sedated using MS-222 before species identification was performed. Species identification was conducted using various morphological, metric, and meristic characteristics.

In cases where morphometric methods were insufficient for species identification, small tissue samples (weighing 1-2 g) were taken from the caudal fins in a way that would not affect the individuals' survival. After taking live photographs of the species, all individuals were returned to their original capture locations.

Figure IX.12 Aquatic Ecosystem Sampling Studies

Fish species were identified according to Geldiay and Balık (2007), Kuru (2004), Fricke et al. (2007), Kottelat and Freyhof (2007), Kuru et al. (2014), and Çiçek et al. (2015, 2020, 2023). For systematic classifications, Nelson et al. (2016), Tan and Armbruster (2018), and van der Laan et al. (2023) were followed, and the latest status of the species was verified using the Catalog of Fishes database (Fricke et al., 2024).

IX.4.3. Significance Criteria

The significance criteria for the impacts on ecology and biodiversity were determined, as high, moderate or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria presented in Chapter 4 ("ESIA Methodology") are described the significance criteria used while sensitivity/value criteria to be used in the scope of ecological impact assessment is summarized in Table IX.11. Detailed explanation of the sensitivity components for each ecosystem component is provided in the following sections.

The IFC Performance Standard 6, Biodiversity Conservation and Sustainable Living Revenue Natural Resource Management rules were used to identify Critical Living Area in the study area. IFC criteria for identifying Critical Habitats include:

Criterion 1: Habitats important for critical and/or endangered species;
Criterion 2: Habitats of significant importance to endemic and/or restricted species;
Criterion 3: Habitats containing significant intensive species or migrating species and/or indigenous species in the global sense;
Criterion 4: Highly threatened and/or unique ecosystems;
Criterion 5: Key evolutionary processes.

Based on these criteria, sensitivity criteria for ecological components within the scope of the Project have been determined as follows:

Table IX.11. Criteria for Sensitivity/Value of Resource/Receptor

Ecosystem Component	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Designated Areas	Internationally Recognised Areas (e.g. UNESCO Natural World Heritage Sites, UNESCO Man and the Biosphere Reserves, Key Biodiversity Areas, and wetlands designated under the Convention on Wetlands of International Importance (Ramsar Convention)).	Nationally designated areas.	N/A
Habitats	Habitats that triggers under the following IFC PS6 Criteria: • Criterion 1: Critically Endangered (CR) and/or Endangered (EN) species; • Criterion 2: Endemic and/or restricted-range species; • Criterion 3: Migratory and/or congregatory species. • Criterion 4: Highly threatened and/or unique; and/or ecosystems • Criterion 5: Key evolutionary processes Habitats that support species of High sensitivity	Areas of habitat that represent >1% distribution within Türkiye or are threatened at a national level. Habitats that support species of Medium sensitivity.	Modified habitats that do not meet the criteria for either medium or high sensitivity. Habitats that support species of Low sensitivity.
Species	Critically Endangered (CR) and/or Endangered (EN) species; Endemic and/or restricted-range species; Migratory and/or congregatory species.	Nationally/regionally important concentrations of a Vulnerable (VU) species, or locally important concentrations of Critically Endangered (CR) and/or Endangered (EN) species. Locally important populations of endemic / rangerestricted species. Populations of migratory species that represent >1 % of the national (Turkish) population.	Locally important populations of Near Threatened (NT) or Vulnerable (VU) species, or locally important populations of species listed on Annexes to the Bern Convention.

IX.4.4. Critical Habitat Assessment Process

Critical habitats are areas with high biological diversity value. Their identification is based on the following key criteria:

i. Habitats supporting Critically Endangered and/or Endangered species.
ii. Habitats of significance for endemic and/or range-restricted species.
iii. Habitats that support globally important populations of migratory species and/or are crucial for migratory corridors.
iv. Highly threatened and/or unique ecosystems.
v. Areas associated with key evolutionary processes.

These criteria are essential for determining critical habitats and ensuring their protection and conservation within the scope of ecosystem assessments and environmental management planning.

The criteria for critical habitats are defined according to IFC PS6, 2019, as follows:

Criterion 1: Critically Endangered (CR) and/or Endangered (EN) species.
Criterion 2: Endemic and/or restricted-range species.
Criterion 3: Migratory and/or congregation species.
Criterion 4: Highly threatened and/or unique ecosystems.
Criterion 5: Key evolutionary processes.

Projects located in areas with high biological diversity value, recognized at the national and/or international level, may require a critical habitat assessment. These areas include:

- IUCN Protected Area Categories: Ia (Strict Nature Reserves), Ib (Wilderness Areas), and II (National Parks).
- Key Biodiversity Areas (KBA) and Important Bird and Biodiversity Areas (IBA).

A critical habitat assessment is vital to ensure that project activities do not adversely affect ecologically important areas and that appropriate conservation measures are incorporated into project planning and execution.

To support informed decision-making, numerical thresholds have been established for four key criteria:

- Presence of Critically Endangered (CR) or Endangered (EN) species, endemic, or range-restricted species.
- Occurrence of migratory species or large aggregations.
- Existence of threatened ecosystems.
- Identification of unique ecosystems.

These thresholds, drawn from the IUCN Global Standard for Key Biodiversity Area Identification, serve as guiding indicators and are not prescriptive. There is no universally automatic formula for critical habitat designation; instead, professional judgment and case-specific analysis are required.

Given frequent limitations in biodiversity data, expert input and site-specific assessments are essential. The critical habitat assessment within the Project Area has been carried out in accordance with these criteria, as defined in IFC 2019 GN6.

To comply with IFC Performance Standard 6 (PS6) requirements and to conduct a critical habitat assessment, an ecologically reasonable analysis unit has been defined for each biodiversity component using Ecologically Appropriate Area of Analysis (EAAA).

Ecologically Appropriate Area of Analysis (EAAA) defines geographical boundaries based on the natural distribution and interaction areas of species, habitats and ecosystems to assess the potential impacts of a project.

In this context, data collection carried out with monitoring studies along the motorway route and in the 400 m buffer zone.

IX.4.5. Ecologically Appropriate Area of Analysis (EAAA)

Assessments conducted within the framework of the Ecologically Appropriate Area of Analysis (EAAA) have successfully evaluated the ecological sensitivities and conservation priorities across the broader project influence area. Preliminary findings have been established, and ongoing biodiversity monitoring is continuing to enhance the understanding of the area's ecological dynamics.

Presence of Critical Habitat

The assessment confirmed the presence of one species of high conservation concern within the Study Area:

Habitat Fragmentation Risk

The project currently demonstrates a low potential to disrupt habitat connectivity within the EAAA. While initial evaluations suggest minimal fragmentation risk, further detailed analysis was conducted to:

- Identify species and ecological zones vulnerable to fragmentation
- Assess movement corridors and maintain ecological connectivity
- Develop and implement adaptive mitigation strategies to prevent habitat disruption during construction and operational phases

These outcomes will inform an Adaptive Management Plan designed to mitigate fragmentation impacts effectively.

Cumulative Impact Considerations

Within the EAAA—spanning the region between Alanya and Antalya—the study addressed cumulative ecological pressures arising from multiple linear infrastructure projects, including existing highways. The cumulative impact assessment incorporated:

- Interactions between the project and other ongoing or planned developments
- Combined effects on habitat quality, species viability, and ecosystem services

The integration of spatial and ecological datasets has allowed for a comprehensive understanding of cumulative impacts, which will inform strategic management and conservation planning.

Compatibility with Species Life Cycles

Seasonal monitoring within the EAAA assessed project compatibility with the life cycles of key migratory and resident species. This analysis facilitated:

- Identification of critical periods and biologically sensitive areas for feeding, breeding, and sheltering
- Adjustment of construction timelines and conservation interventions to avoid disruption during key ecological windows
- Enhancement of mitigation measures in alignment with IFC PS6 requirements and biodiversity conservation goals

IX.5. Findings for Ecology and Biodiversity

IX.5.1. Natural and Modified Habitats

IFC PS6 (Biodiversity Conservation and Sustainable Management of Living Natural Resources) defines Natural Habitats as areas composed of viable assemblages of plant and/or animal species of largely native origin, and/or where human activity has not essentially modified an area's primary ecological functions.

Key principles related to Natural Habitats under PS6:

- Projects should avoid significant conversion or degradation of natural habitats.
- If avoidance is not possible, mitigation measures should be implemented, following the mitigation hierarchy: Avoid, Minimize, Restore, Offset.

Modified Habitats are areas that have been significantly altered by human activity. These habitats may contain a mix of native and non-native species, and their ecological structure and functions have been heavily transformed due to development, agriculture, or resource extraction.

Typical characteristics of Modified Habitats:

- Substantial human influence: Examples include urban areas, industrial zones, agricultural lands, and plantation forests.
- Reduced native biodiversity: Native species may be present but often in fragmented or altered populations.
- Ecological processes changed: Natural hydrology, nutrient cycles, and other processes may be altered or suppressed.

While these areas are often less ecologically valuable than Natural or Critical Habitats, they can still provide important ecosystem services and serve as refugia or corridors for biodiversity.

IFC PS6 guidance for Modified Habitats:

- Projects in these areas are expected to minimize further degradation and enhance biodiversity where possible.
- Where feasible, promote the restoration of ecological functions and support sustainable land use practices.

The Natural and Modified Habitats within the study area were identified through a combination of literature review, satellite imagery analysis using Google Earth and CORINE 2018 data, and comprehensive field surveys conducted by qualified flora and fauna experts. Natural Habitats, as defined by IFC Performance Standard 6 (PS6), are areas composed of viable assemblages of native species where ecological processes and functions are largely intact and human-induced modifications are minimal or absent. Within the study area, these habitats support self-sustaining populations of plants and animals of predominantly native origin and maintain essential ecological functions such as nutrient cycling, soil stabilization, and habitat connectivity. Modified habitats, by contrast, may exhibit some level of human alteration but may still retain significant ecological value, supporting native species and contributing to the overall biodiversity of the landscape.

During field surveys, certain areas within the study site were identified as Critical Habitat in accordance with IFC PS6, which defines Critical Habitat as follows:

- Habitat of significant importance to Critically Endangered and/or Endangered species;
- Habitat of significant importance to endemic and/or restricted-range species;
- Habitat supporting globally significant concentrations of migratory species and/or congregatory species;
- Highly threatened and/or unique ecosystems; and/or
- Areas associated with key evolutionary processes. These areas provide essential ecological functions and refuge for species that trigger Critical Habitat Criterions of PS6, making their protection a priority in project planning and impact mitigation.

The Antalya-Alanya Motorway route, where the Project will be carried out, features a vegetation structure shaped by the Mediterranean climate. Natural vegetation in the area includes maquis and coniferous natural forest habitats. The Project corridor passes through a variety of terrestrial ecosystems, including degraded forest areas, scrub, agricultural land, vineyards and gardens, greenhouse areas, and residential zones. It is observed that the Project Area encompasses six natural habitat types and six modified habitat type. The areas and percentages of EUNIS habitat types within the project study area are given in Table IX.12. Maps showing the habitat types in the project area are given in Figure IX.13, Figure IX.14, Figure IX.15, Figure IX.16, and Figure IX.17

Table IX.12. EUNIS Habitat Types and Their Respective Areas within the Project Study Area

EUNIS Habitat Code	EUNIS Habitat Type	Antalya-Alanya Motorway Project		
		Area (m2)	Area (ha)	Percent (%)
Natural Habitats				
C2	Surface running waters	366,990	37	0.5
S5	Maquis, arborescent matorral and thermo-Mediterranean scrub	3,471,732	347	5.1
S6	Garrigue	4,468,176	447	6.5

4

Figure IX.16. EUNIS Habitat Types within the Project Area (Part 4 of 5)

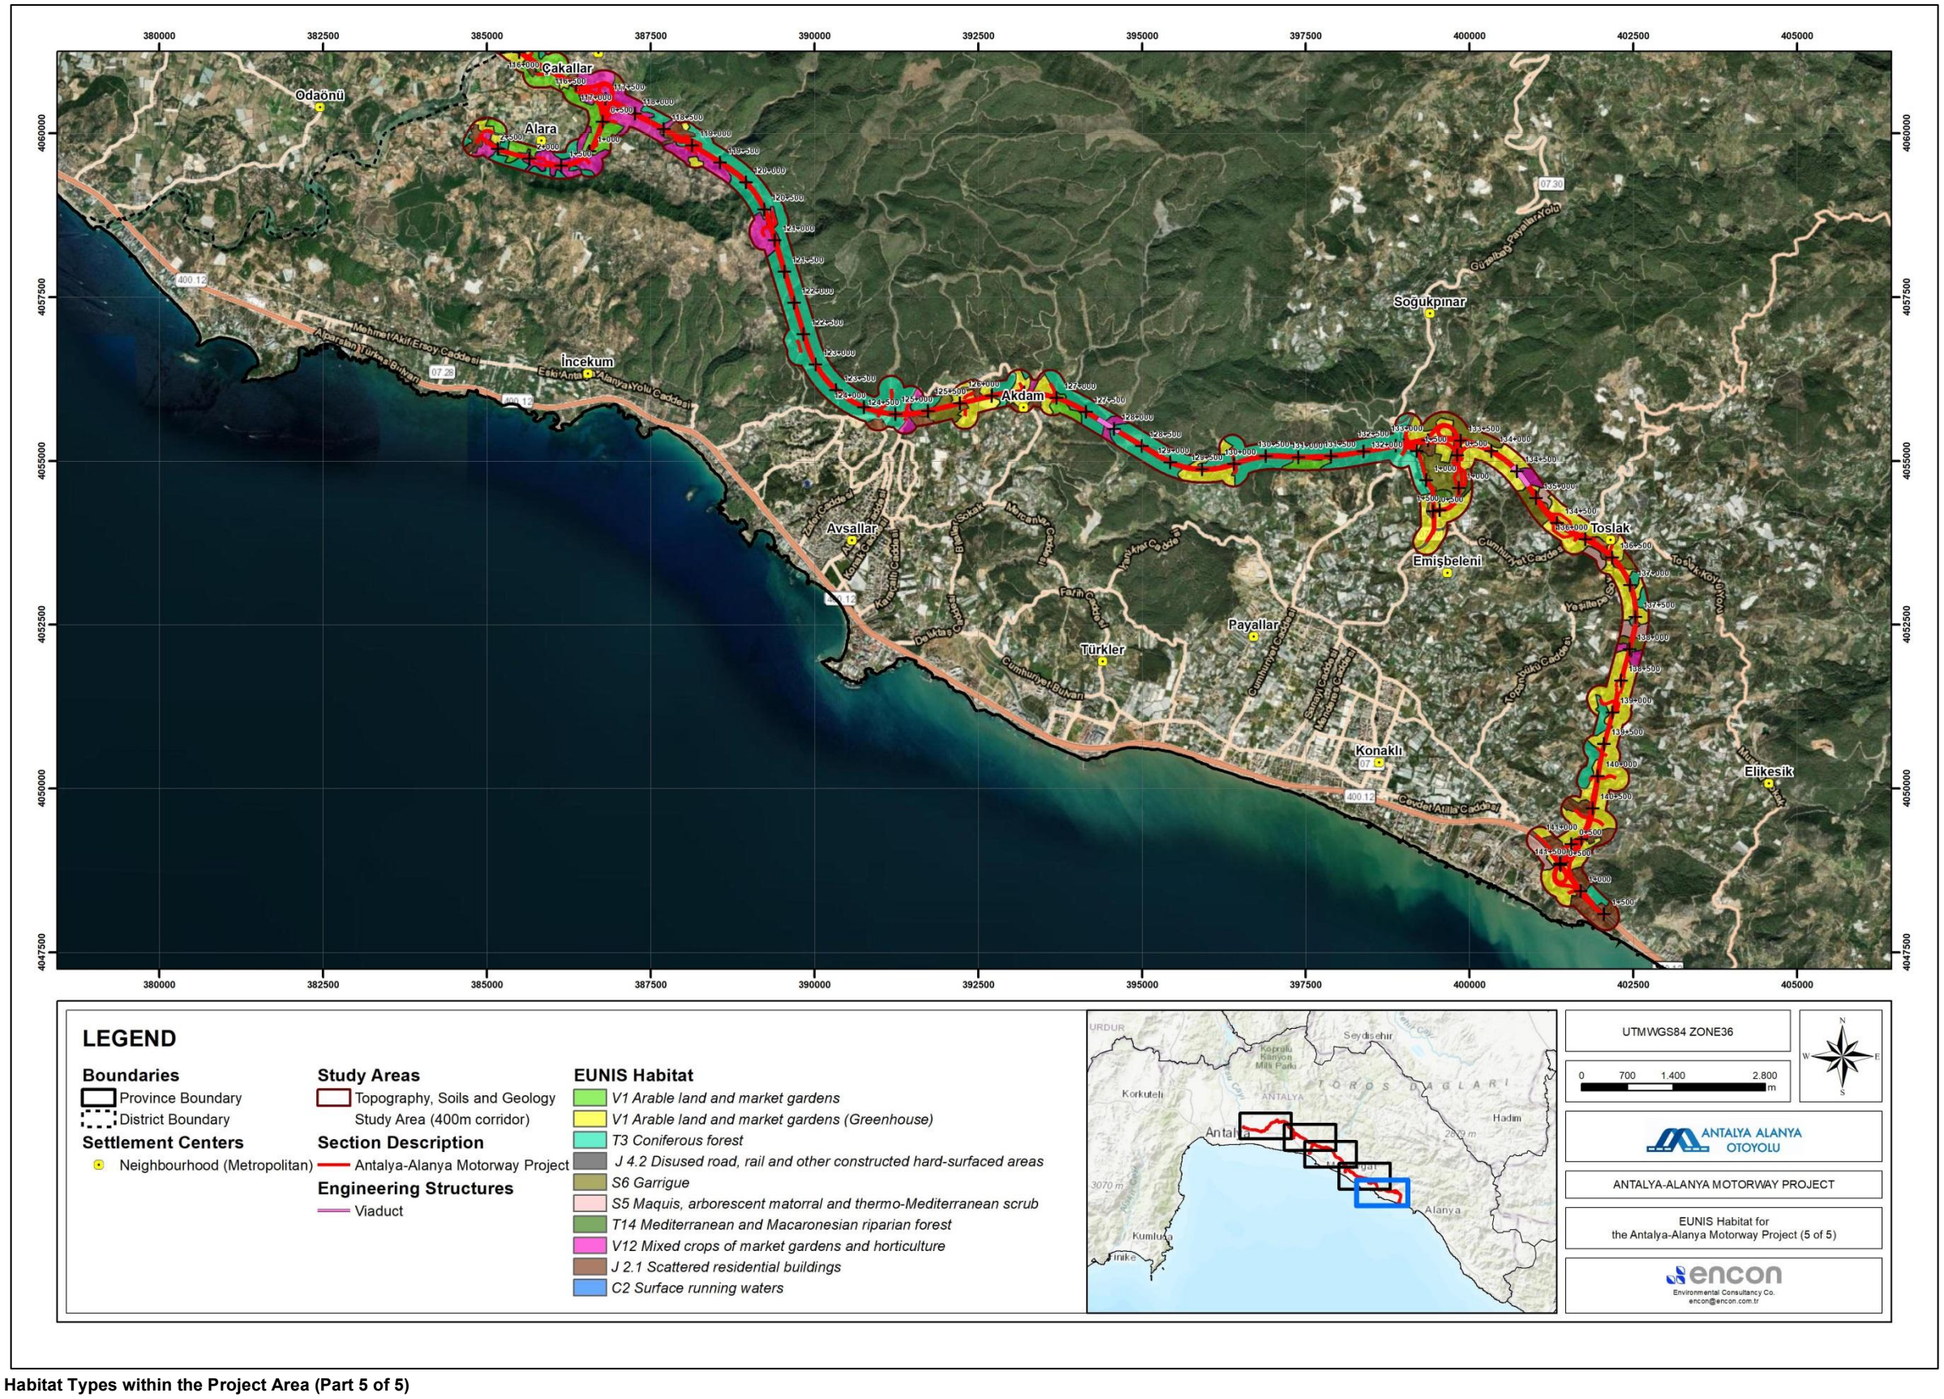

Figure IX.17. EUNIS Habitat Types within the Project Area (Part 5 of 5)

Photographs of habitat types are presented in Figure IX.18 to Figure IX.22.

C2 - Surface running waters: Running waters, including springs, streams and temporary water courses.

G1.1 - Riparian and Gallery Forests Dominated by *Alnus, Betula*, *Populus*, or *Salix* Genera: Riparian woods of the boreal, boreo-nemoral, nemoral and submediterranean and steppe zones, with one or few dominant species, typically *Alnus*, *Betula*, *Populus* or *Salix*. Includes woods dominated by narrow-leaved willows *Salix alba*, *Salix elaeagnos*, *Salix purpurea*, *Salix viminalis* in all zones including the mediterranean. Excludes riverine scrub of broad-leaved willows, e.g. *Salix aurita*, *Salix cinerea*, *Salix pentandra.*

Figure IX.18 C2 and G1.1 Habitats in the Project Area

S5 - Maquis, arborescent matorral and thermo-Mediterranean scrub: Evergreen sclerophyllous or lauriphyllous shrub vegetation, with a closed or nearly closed canopy structure, having nearly 100% cover of shrubs, with few annuals and some vernal geophytes; trees are nearly always present, some of which may be in shrub form. Shrubs, sometimes tall, of *Arbutus*, *Cistus*, *Cytisus*, *Erica*, *Genista*, *Lavandula*, *Myrtus*, *Phillyrea*, *Pistacia*, *Quercus* and *Spartium* are typical. These include pseudomaquis, in which the dominants are mixed deciduous and evergreen shrubs.

Figure IX.19. S5 Habitat in the Project Area

S6 - Garrigue: Evergreen sclerophyllous or lauriphyllous shrub vegetation, with an open canopy structure and some bare ground, usually with many winter annuals and vernal geophytes. Low shrubs of *Cistus*, *Lavandula*, *Rosmarinus* and *Stoechas* are usually present, and there may be some larger shrubs and scattered trees. Garrigue is found mostly in the Mediterranean, Macaronesian and Pontic regions, where it typically derives from degradation or regrowth of broad-leaved evergreen forests (T2), but it extends into deciduous forest areas in the supra-Mediterranean zone and sub-Mediterranean zones and into steppe areas in Anatolia. Additionally, it includes scrubby land with mainly herbaceous vegetation and a large component of unpalatable non-vernal monocots (*Asphodelus*, *Urginea*) and thistles, provided that shrub cover exceeds 10%.

Figure IX.20 S5 and S6 Habitats in the Project Area

S7.211 - Aegean *Sarcopoterium phrygana*: *Sarcopoterium spinosum*-dominated formations, by far the commonest *phrygana* facies, widespread in the Aegean archipelagoes and Crete, with local outposts in peninsular Greece, the Ionian islands and coastal Anatolia.
T3 - Coniferous forest: Forest dominated by coniferous trees, mainly evergreen (*Abies*, *Cedrus*, *Picea*, *Pinus*, *Taxus*, and Cupressaceae) but also deciduous *Larix*. This also includes forest with mixed coniferous and deciduous broadleaved trees, if the cover by coniferous trees exceeds that of deciduous trees. Old plantations which have many of the characteristics of natural or semi-natural forests are included, more intensively managed, and less natural, forests are included in vegetated man-made habitats.

Figure IX.21. T3 Habitat in the Project Area

T14 - Mediterranean and Macaronesian riparian forest: Deciduous broadleaved forest, most commonly dominated by poplars (*Populus*), willows (*Salix*) or oriental plane (*Platanus orientalis*), on periodically flooded alluvia or gravel terraces and streamsides in humid localities 39 in the Mediterranean and Macaronesia. Also includes streamside forests with *Rhododendron ponticum* and *Betula pendula* var. *fontqueri* in Spain.

V1 - Arable land and market gardens: Croplands planted for annually or regularly harvested crops other than those that carry trees or shrubs. They include fields of cereals, of sunflowers and other oil seed plants, of beets, legumes, fodder, potatoes and other forbs. Croplands comprise intensively cultivated fields as well as traditionally and extensively cultivated crops with little or no chemical fertilisation or pesticide application. Faunal and floral quality and diversity depend on the intensity of agricultural use and on the presence of borders of natural vegetation between fields.

Figure IX.22. V1 Habitat in the Project Area

IX.5.2. Terrestrial Flora

As a result of the studies carried out along the Antalya-Alanya Motorway route, 214 species and subspecies taxa belonging to 58 families were identified. Among these, 7 species are endemic taxa (*Eryngium kotschyi, Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis and Sideritis congesta*) which are considered restricted.

The general floristic structure of Antalya province is composed of maquis vegetation, which is the basic element of the Mediterranean coastal ecosystem. This vegetation is dominant along the Mediterranean coast of Türkiye.

As a result of the field study, 221 plant species belonging to 60 families were identified. Among the species that make up the flora of the area, the Asteraceae family is the most dominant with 29 species (13.1%), followed by Lamiaceae, Fabaceae, and Poaceae families, each with 18 taxa (8.1%). The Brassicaceae family follows with 15 taxa (6.8%), the Apiaceae family with 10 taxa (4.7%), and the Boraginaceae family with 9 taxa (4.1%). Other families, such as Rosaceae with 6 taxa (2.7%) and Caryophyllaceae and Ranunculaceae with 5 taxa (2.3%) each, are also represented. Other families are represented by four or fewer taxa. The top five families with the most taxa in the Project Area are also among the top 10 families with the most taxa in Türkiye's flora.

Photographs of some of the plant species identified during the monitoring studies carried out in and around the Project Area and as a result of observations made in and around the site in Annex-10.
As a result of the literature and field study, 7 endemic plants were found among the 221 plant taxa identified in the Project Area and its immediate vicinity. These are; *Eryngium kotschyi, Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis and Sideritis congesta*. There are no non-endemic but rare plant species in the area. Except for *Pyrus serikensis*,

these species have been observed as having a “Moderate” amount of individuals (20-100) around the study area. *Pyrus serikensis* assessed as having a “Low” relative abundance. Field observations recorded approximately 20 individuals of *Pyrus serikensis* (20 is the expected number at the moment maximum individual number is 10) in localized patches within the maquis habitat, with possibility of more. More detail in this regard is given in IX.7.

Among the plant taxa identified in and around the Project Area, *Pyrus serikensis* falls under the EN (Endangered) category, four species (*Eryngium kotschyi*, *Phlomis lycia*, *Phlomis monocephala*, and *Sideritis congesta*) are categorized as LC (Least Concern) and two species (*Phlomis leucophracta* and *Phlomis nissolii*) as NE (Not Evaluated). Therefore, considering the IUCN category, it was determined that apart from *Pyrus serikensis*, there are no endangered species in the area.

The IUCN category of *Phlomis monocephala* and *Sideritis congesta* species, which are regional endemic species identified from the area as a result of the fieldwork carried out in the Project Area, is “Least Concern, LC”. The IUCN Red List category for the widespread endemic species *Eryngium kotschyi* is “LC”. The list of flora elements identified from the area within the scope of the Project is given in Annex-10.

According to the CITES Convention, among the 221 taxa identified in the Project Area and its surrounding environment, only *Barlia robertiana* is listed in Appendix II. The remaining 220 species are not listed in any CITES appendix.

According to the Bern Convention, none of the 221 taxa identified in the Project Area and its surrounding environment are listed in the convention's appendices.

According to the Habitat Directive, there are no listed species among the 221 taxa identified in the Project Area and its immediate vicinity.

Relative abundance and presence species information regarding terrestrial flora is given in Table IX.13.

Table IX.13 Relative Abundance and Presence for Terrestrial Flora Species

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)
Terrestrial Flora	*Pyrus serikensis*	Low	Y
	Eryngium kotschyi	Moderate	Y
	Phlomis leucophracta	Moderate	Y
	Phlomis lycia	Moderate	Y
	Phlomis monocephala	Moderate	N
	Phlomis nissolii	Moderate	Y
	Sideritis congesta	Moderate	Y
	Barlia robertiana	Moderate	Y

IX.5.3. Terrestrial Fauna

IX.5.3.1. Amphibians

Along the Motorway route, there are many different habitat types such as agricultural areas, forest areas, maquis vegetation, streams and degraded areas. Rivers within the Project Area provide areas suitable for the breeding of amphibians. In addition, keeping the soil constantly moist due to agricultural irrigation and irrigation ponds provide suitable habitats for the reproduction of amphibians.

As a result of literature and field studies, five amphibian species belonging to four families of the Anura order were identified along the Motorway route. Regarding the species identified in the Project Area information can be found in Annex-10 as a table. Photographs of the amphibian species identified in the area are also presented in Annex-10.

Lyciasalamandra atifi is endemic to the region among the five species of amphibian identified in and around the Project Area as a result of literature and fieldwork. *Lyciasalamandra atifi* -Associated with the T3 - Coniferous Forest habitat type- has a highly restricted regional distribution and occurs at higher altitudes outside the direct project footprint. Monitoring studies for this species were conducted at an elevation where the motorway is ecologically suitable for ecological habitat, taking into account the natural distribution area of the species. No individuals were found in most of the identified areas. Only specimens were found 5 km north of the motorway at an altitude of 500 m.

There are no non-endemic but rare species in the area.

Among the amphibians identified in and around the Project Area, one species is categorized as EN, three species are categorized as LC, and no assessment has been made yet for the *Hyla orientalis* (NE). Considering the IUCN category, it is understood that *Lyciasalamandra atifi* which is endemic to the area, is a threatened species.

According to the CITES Convention, there are no species included in the relevant lists among the species detected in the Project Area and its immediate surroundings.

According to the Habitat Directive, there are no listed species among the amphibian species identified in the Project Area and its immediate vicinity.

Among the amphibian species encountered in the area, there are species listed under Assessment According to Central Hunting Commission Decisions (CHCD). These species, like other fish species in Türkiye, are considered under protection by the Ministry of Agriculture and Forestry.

Among the amphibian species identified in the Project Area and its immediate surroundings, there is no endangered species other than *Lyciasalamandra atifi*, which is endemic and endangered species according to IUCN, included in Bern and CITES conventions and Habitat Directive. Therefore, monitoring studies should be carried out for this species. This land salamander, which is endemic to Türkiye, is in the EN category and is under threat for many reasons such as climate change, collection, habitat destruction, alien species, and urbanization. Although the motorway corridor falls within its broader natural distribution range, no individuals have been recorded in suitable habitats within the Project Area. In February-March 2025, the species was observed in northern sections of the Project Area, outside the altitudinal range of its known distribution. Regarding *Lyciasalamandra atifi*, only 4 individuals were recorded during surveys, and all of them were outside of the Study Area. Other amphibian species in and around the Project Area have been assessed as having a wide distribution in general. Observation method and observed stations for amphibians is given in Table IX.14 and fauna sampling points are given in Figure IX.2.

Table IX.14 Observation Method and Observed Stations for Amphibians

Scientific Name	Observation Method	Observed Stations
Lyciasalamandra atifi (Başoğlu, 1967)	L	L
Pelophylax bedriagae (Camerano, 1882)	O+L	All Fauna Sampling Stations
Bufo verrucosissimus Pallas, 1814	O+L	All Fauna Sampling Stations
Bufotes viridis (Laurenti, 1768)	O+L	All Fauna Sampling Stations
Hyla orientalis Bedriaga, 1890	O+L	All Fauna Sampling Stations

** O: Observed, L: Literature*

IX.5.3.2. Reptiles

Field studies conducted in areas within the project application area and ecological impact boundaries and interviews with local people were evaluated together with literature data and the reptile species existing in the area were determined. As a result of observations and interviews in the field, 25 species belonging to 14 families from the Testudines and Squamata orders were identified in the Project Area and ecological impact areas. These include two turtle species, 13 lizards and 10 snake species (Annex 10, Table 9.6).

When the distribution of species according to families is analyzed, Colubridae is the most dominant family, represented by 5 species (20.0%), followed by Lacertidae with four species (16.0%), Scincidae with three species (12.0%), and Gekkonidae and Natricidae, each represented by two species (8.0%). The remaining families are each represented by a single species.

Among the reptile species identified within the Project Area and its vicinity, out of the 25 species with a potential distribution in the area, *Testudo graeca* is classified as VU according to IUCN conservation status, 20 species are categorized as LC, and four species have not yet been evaluated (NE).

Testudo graeca, which is considered to be under threat (VU), has a wide distribution in Türkiye. There are also healthy populations in the regions where it is distributed in Türkiye. The category determined for this species was made considering European populations. However, since the threat category has not been determined for Türkiye, this species should be monitored and whether the motorway project will pose any threat to the species and, if so, the measures to eliminate this threat should be determined and implemented by the contractor.

Among the reptile species that are likely to be encountered in the area, two species are listed in Appendix II of the CITES Convention.

All of the reptile species identified in the area are listed under the Bern Convention, with 8 species included in Annex II and 17 species in Annex III.
According to the EU Habitat Directive, 12 of the 25 reptile species identified in and around the Project Area are listed in Annex 10.

Among the reptile species encountered in the area, there are no species listed under CHCD. These species, like other fish species in Türkiye, are considered under protection by the Ministry of Agriculture and Forestry.

Among the 25 reptile species identified in the Project Area and its surrounding environment, there are four endemic lizard species: *Ablepharus anatolicus*, *Anatololacerta İbrahimi*, *Lacerta pamphylica*, and *Blanus aporus*.

Additionally, there are non-endemic species that are considered rare. It was observed that all the reptile species identified along the project route are species with wide distributions. Most of the reptile species in and around the Project Area have been assessed as having a "Low" relative abundance with wide distributions. More details are presented regarding this in section IX.7.

Relative abundance and species presence information regarding amphibians and reptile species is given in Table IX.16. Observation stations and observation method for reptiles is given in Table IX.15.

Table IX.15 Scientific Name, Observation Method, and Observed Stations

Scientific Name	Observation Method	Observed Stations
Testudo graeca Linnaeus, 1758	O+L	All Fauna Sampling Stations
Mauremys rivulata (Valenciennes, 1833)	L	L
Hemidactylus turcicus (Linnaeus, 1758)	L	L
Mediodactylus danilewskii (Satrauch, 1887)	L	L
Laudakia stellio (Linnaeus, 1758)	O+L	All Fauna Sampling Stations
Chamaeleo chamaeleon (Linnaeus, 1758)	O+L	All Fauna Sampling Stations
Pseudopus apodus (Pallas, 1775)	O+L	All Fauna Sampling Stations
Anatololacerta ibrahimi (Eiselt & Schmidtler 1987)	L	L
Lacerta pamphylica Schmidtler, 1975	O+L	All Fauna Sampling Stations
Ophisops elegans Ménétriés, 1832	O+L	All Fauna Sampling Stations
Phoenicolacerta laevis (Gray, 1838)	O+L	All Fauna Sampling Stations
Ablepharus anatolicus Schmidtler, 1997	L	L
Heremites auratus (Linnaeus, 1758)	L	L
Heremites vittatus (Olivier, 1804)	L	L
Blanus aporus Werner, 1898	L	L
Xerotyphlops vermicularis (Merrem, 1820)	L	L
Dolichophis jugularis (Linnaeus, 1758)	L	L

Table IX.16 Relative Abundance and Presence of Species for Reptile and Amphibian Species

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)
Amphibians and Reptiles	*Lyciasalamandra atifi*	Low	N
	Testudo graeca	Moderate	Y
	Lacerta pamphylica	Low	N
	Anatololacerta ibrahimi	Low	N
	Ablepharus anatolicus	Low	N
	Blanus aporus	Low	N
	Other herpetofauna species	Moderate	Y

IX.5.3.3. Birds

The area where the project is located generally consists of agricultural areas and maquis habitats. During the field study conducted in the area, it was determined that bird species that prefer these habitats are dominant. In addition, it has been determined that aquatic habitats in the areas where streams are located in the area are important for semi-aquatic water birds. This depends on what the birds use the area for.

As a result of observations and interviews in the field, it was determined that a total of 124 bird species belonging to 33 families from nine orders live in the Project Area and ecological impact areas (Annex 10, Table 9.7). There are no endemic bird species among the possible bird species identified by field work in the area and mentioned in previous studies, and all of their species have been observed to consist of species that can be considered as widely distributed and cosmopolitan. When looking at the distribution of species, it is observed that 88 species (71.0%) recorded in the field are passerine birds (Passeriformes). The orders that include species migrating by soaring (Accipitriformes, Falconiformes, and Ciconiiformes) consist of 16 species in total, which corresponds to 12.9% of the species count (Figure IX.23).

As a result of bird observations and literature searches along the motorway route, the majority of the species (88 species; 71%) were found to belong to the order Passeriformes followed by Accipitriformes (10 species, 8.1%), Strigiformes (five species, 4.0%), Columbiformes and Falconiformes (four species each, 3.2%), and Cuculiformes (three species, 2.4%).

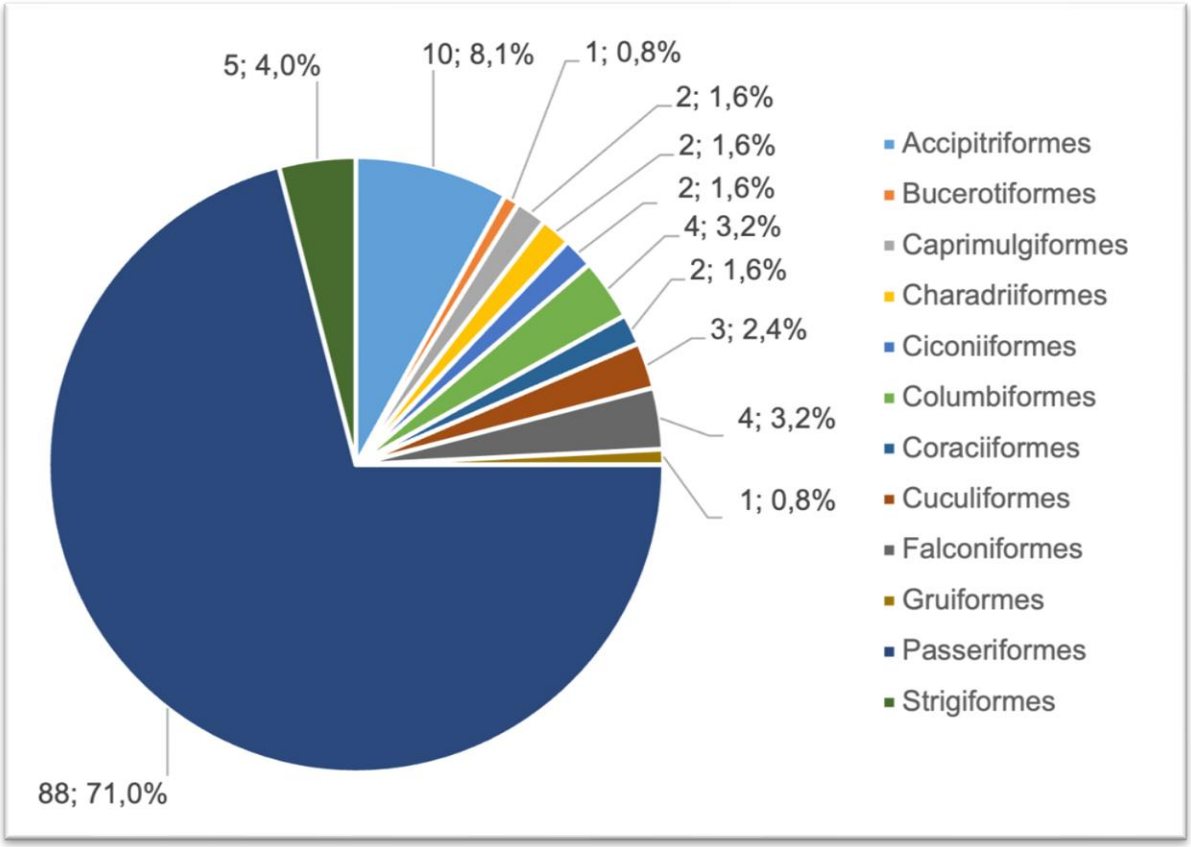

Figure IX.23 Distribution of number of bird species based on orders

When the distribution of species according to families is analyzed, Muscicapidae is the most dominant family, represented by 14 species (11.3%), followed by Motacillidae (11 species, 8.9%), Accipitridae (nine species, 7.3%), Sylviidae and Fringillidae (eight species each, 6.5%), Acrocephalidae (seven species, 5.6%), and Emberizidae, Hirundinidae, and Strigidae (five species each, 4.0%)

Photographs of some of the bird species observed during the monitoring studies carried out in the Project Area and its immediate surroundings and as a result of the monitoring studies carried out in the area and its surroundings in the past are given in Annex-10. The table regarding the bird species found and likely to be found in the Project Area and its immediate surroundings, along with their conservation status is presented in Annex-10.

Among the 124 bird species recorded in the Project Area and its surroundings, their IUCN conservation statuses are as follows: 1 species classified as Endangered (EN) (*Neophron percnopterus*), 1 species classified as Vulnerable (VU) (*Streptopelia turtur*), 1 species classified as Near Threatened (NT) (*Circus macrourus*), 1 species classified as Not Evaluated (NE) (*Corvus cornix*) and the remaining 120 species fall under the Least Concern (LC) category.

Considering the presence of *Streptopelia turtur* and *Neophron percnopterus*, which are listed in threatened categories, it has been determined that the Project Area does not serve as a critical site for breeding, feeding, or wintering for these species.

In the evaluation made according to the 2008 Red List for Birds of Türkiye (=RDB), 15 species among the bird species determined to be distributed in the plantation area and areas within its impact area are A1.2; 37 species A.2; 38 species A.3; 16 species A.3.1; 5 species A.4; 6 species A.5; two species A.6; one species A.7; one species B.1.2, two species falls into the B.3 category and one species falls into the B.6 category.

Among the birds that are likely to be encountered in the area, it has been determined that two species are listed in Annex I, 18 species are listed in Annex-II and one species is listed in Annex-III within the scope of the CITES agreement.

Among the 124 species identified in the Project Area and its immediate surroundings, there are no species listed according to the Bern Convention. Of the bird species identified in the area, 81 are listed in Annex-II and 40 in Annex III, within the scope of the Bern Convention.

According to the EU bird directive, among the 124 bird species identified in and around the Project Area, 18 species are listed in Annex I, two species in Annex II/A, and six species in Annex II/B. Among the bird species that are likely to be encountered in the area, 16 species are listed in Annex-I (Game Animals Protected by CHCD) and six bird species are listed in Annex-II (Species Allowed to Hunt in Certain Periods).

According to the occurrence of 124 bird species listed in Türkiye in Annex 10 - Table 9.7; 38 species are classified as native (N), 21 species as winter visitors (WV), 28 species as summer visitors (SV) and 37 species as transit migrants (T).

Based on literature reviews and field studies, none of the 124 bird species identified in the Project Area and its surroundings are endemic. Additionally, no non-endemic but rare bird species were recorded. The majority of the species identified consist of widely distributed cosmopolitan species. Observation method for birds is given in Table IX.17

Table IX.17 Scientific Name and Type of Detection for Birds

Scientific Name	Common Name	Type of Detection
Accipitridae		
Accipiter nisus (Linnaeus, 1758)	Eurasian Sparrowhawk	O+L
Aquila chrysaetos (Linnaeus, 1758)	Golden Eagle	L
Buteo buteo (Linnaeus, 1758)	Eurasian Buzzard	O+L
Buteo rufinus (Cretzschmar, 1827)	Long-Legged Buzzard	O+L
Circaetus gallicus (Gmelin, 1788)	Short-Toed Snake-Eagle	O+L
Circus aeruginosus (Linnaeus, 1758)	Western Marsh-Harrier	O+L
Circus cyaneus (Linnaeus, 1766)	Hen Harrier	L
Circus macrourus (Gmelin, 1770)	Pallid Harrier	L
Neophron percnopterus (Linnaeus, 1758)	Egyptian Vulture	L
Pandionidae		
Pandion haliaetus (Linnaeus, 1758)	Osprey	L
Scolopacidae		
Actitis hypoleucos Linnaeus, 1758	Common Sandpiper	O+L

Tringa glareola Linnaeus, 1758	Wood Sandpiper	O+L
Upupidae		
Upupa epops Linnaeus, 1758	Common Hoopoe	O+L
Apodidae		
Apus apus (Linnaeus, 1758)	Common Swift	O+L
Tachymarptis melba (Linnaeus, 1758)	Alpine Swift	O+L
Ciconiidae		
Ciconia ciconia (Linnaeus, 1758)	White Stork	O+L
Ciconia nigra (Linnaeus, 1758)	Black Stork	L
Columbidae		
Columba livia Gmelin, 1789	Rock Dove	O+L
Spilopelia senegalensis (Linnaeus, 1766)	Laughing Dove	O+L
Streptopelia decaocto FrivaULszky, 1838	Eurasian Collared-Dove	O+L
Streptopelia turtur (Linnaeus, 1758)	European Turtle-Dove	O+L
Alcedinidae		
Alcedo atthis (Linnaeus, 1758)	Common Kingfisher	O+L
Coraciidae		
Coracias garrulus Linnaeus, 1758	European Roller	O+L
Cuculidae		
Clamator glandarius (Linnaeus, 1758)	Great Spotted Cuckoo	O+L
Cuculus canorus Linnaeus, 1758	Common Cuckoo	L
Meropidae		
Merops apiaster Linnaeus, 1758	European Bee-Eater	O+L
Falconidae		
Falco columbarius Linnaeus, 1758	Merlin	L
Falco peregrinus Tunstall, 1771	Peregrine Falcon	L
Falco subbuteo Linnaeus, 1758	Eurasian Hobby	L
Falco tinnunculus Linnaeus, 1758	Common Kestrel	O+L
Rallidae		
Gallinula chloropus (Linnaeus, 1758)	Common Moorhen	O+L
Acrocephalidae		
Acrocephalus arundinaceus (Temminck & Schlegel, 1847)	Great Reed-Warbler	O+L
Acrocephalus melanopogon (Temminck, 1823)	Moustached Warbler	L
Acrocephalus palustris (Bechstein, 1798)	Marsh Warbler	L
Acrocephalus schoenobaenus (Linnaeus, 1758)	Sedge Warbler	L
Acrocephalus scirpaceus (Hermann, 1804)	Common Reed-Warbler	O+L

Hippolais icterina (Vieillot, 1817)	Icterine Warbler	L
Iduna pallida (Ehrenberg, 1833)	Olivaceous Warbler	O+L
Alaudidae		
Calandrella brachydactyla (Leisler, 1814)	Greater Short-Toed Lark	O+L
Galerida cristata (Linnaeus, 1758)	Crested Lark	O+L
Lullula arborea (Linnaeus, 1758)	Woodlark	L
Melanocorypha calandra (Linnaeus, 1766)	Calandra Lark	O+L
Corvidae		
Corvus corax Linnaeus, 1758	Common Raven	O+L
Corvus cornix Linnaeus, 1758	Hooded Crow	O+L
Garrulus glandarius (Linnaeus, 1758)	Eurasian Jay	O+L
Emberizidae		
Emberiza caesia Cretzschmar, 1828	Cretzschmar's Bunting	L
Emberiza calandra Linnaeus, 1758	Corn Bunting	O+L
Emberiza cia Linnaeus, 1766	Rock Bunting	L
Emberiza hortulana Linnaeus, 1758	Ortolan Bunting	L
Emberiza melanocephala Scopoli, 1769	Black-Headed Bunting	L
Fringillidae		
Carduelis carduelis (Linnaeus, 1758)	European Goldfinch	O+L
Chloris chloris (Linnaeus, 1758)	European Greenfinch	O+L
Coccothraustes coccothraustes (Linnaeus, 1758)	Hawfinch	L
Fringilla coelebs Linnaeus, 1758	Common Chaffinch	O+L
Fringilla montifringilla Linnaeus, 1758	Brambling	L
Linaria cannabina (Linnaeus, 1758)	Common Linnet	L
Serinus serinus (Linnaeus, 1766)	European Serin	O+L
Serinus spinus (Linnaeus, 1758)	Eurasian Siskin	L
Hirundinidae		
Cecropis daurica Linnaeus, 1771	Red-Rumped Swallow	O+L
Delichon urbicum (Linnaeus, 1758)	Northern House Martin	O+L
Hirundo rustica Linnaeus, 1758	Barn Swallow	O+L
Riparia riparia Linnaeus, 1758	Collared Sand Martin	O+L
Ptyonoprogne rupestris Scopoli, 1769	Eurasian Crag Martin	L
Laniidae		
Lanius collurio Linnaeus, 1758	Red-Backed Shrike	O+L
Lanius minor Gmelin, 1788	Lesser Grey Shrike	L
Lanius nubicus Lichtenstein, 1823	Masked Shrike	O+L

Lanius senator Linnaeus, 1758	Woodchat Shrike	O+L
Locustellidae		
Locustella fluviatilis (Wolf, 1810)	River Warbler	L
Locustella luscinioides (Savi, 1824)	Savi's Warbler	L
Locustella naevia (Boddaert, 1783)	Common Grasshopper-Warbler	L
Motacillidae		
Motacilla alba Linnaeus, 1758	White Wagtail	O+L
Motacilla cinerea Tunstall, 1771	Grey Wagtail	L
Motacilla citreola Pallas, 1776	Citrine Wagtail	L
Motacilla flava Linnaeus, 1758	Western Yellow Wagtail	O+L
Anthus campestris Linnaeus, 1758	Tawny Pipit	L
Anthus cervinus Pallas, 1811	Red-Throated Pipit	L
Anthus godlewskii Taczanowski, 1876	Blyth`S Pipit	L
Anthus pratensis Linnaeus, 1758	Meadow Pipit	L
Anthus richardi Vieillot, 1818	Richard's Pipit	L
Anthus spinoletta Linnaeus, 1758	Water Pipit	L
Anthus trivialis Linnaeus, 1758	Tree Pipit	L
Muscicapidae		
Luscinia luscinia (Linnaeus, 1758)	Thrush Nightingale	L
Luscinia megarhynchos (Brehm, 1831)	Common Nightingale	O+L
Luscinia svecica (Linnaeus, 1758)	Bluethroat	L
Monticola saxatilis (Linnaeus, 1776)	Rufous-Tailed Rock-Thrush	L
Monticola solitarius (Linnaeus, 1758)	Blue Rock-Thrush	L
Oenanthe deserti (Temminck, 1825)	Desert Wheatear	L
Oenanthe finschii (Heuglin, 1869)	Finsch's Wheatear	L
Oenanthe hispanica (Linnaeus, 1758)	Black-Eared Wheatear	O+L
Oenanthe isabellina (Temminck, 1829)	Isabelline Wheatear	O+L
Oenanthe oenanthe (Linnaeus, 1758)	Northern Wheatear	O+L
Phoenicurus ochruros (Gmelin, 1774)	Black Redstart	O+L
Phoenicurus phoenicurus (Linnaeus, 1758)	Common Redstart	L
Saxicola rubetra (Linnaeus, 1758)	Whinchat	L
Saxicola torquatus (Linnaeus, 1766)	Common Stonechat	O+L
Paridae		
Cyanistes caeruleus (Linnaeus, 1758)	Eurasian Blue Tit	L
Parus major Linnaeus, 1758	Great Tit	O+L
Periparus ater (Linnaeus, 1758)	Coal Tit	O+L

Passeridae		
Passer domesticus (Linnaeus, 1758)	House Sparrow	O+L
Passer hispaniolensis (Temminck, 1820)	Spanish Sparrow	L
Passer montanus (Linnaeus, 1758)	Eurasian Tree Sparrow	L
Phylloscopidae		
Phylloscopus collybita (Vieillot, 1817)	Common Chiffchaff	O+L
Phylloscopus orientalis (Brehm, 1855)	Eastern Bonelli's Warbler	L
Phylloscopus sibilatrix (Bechstein, 1793)	Wood Warbler	L
Phylloscopus trochilus (Linnaeus, 1758)	Willow Warbler	O+L
Pycnonotidae		
Pycnonotus xanthopygos (Ehrenberg, 1833)	White-Spectacled Bulbul	O+L
Sittidae		
Sitta neumayer Michahelles, 1830	Western Rock Nuthatch	O+L
Scotocercidae		
Cettia cetti (Temminck, 1820)	Cetti's Warbler	O+L
Sturnidae		
Sturnus vulgaris Linnaeus, 1758	Common Starling	O+L
Sylviidae		
Curruca cantillans (Pallas, 1764)	Subalpine Warbler	L
Curruca communis Latham, 1787	Common Whitethroat	O+L
Curruca crassirostris (Gmelin, 1789)	Eastern Orphean warbler	L
Curruca curruca (Linnaeus, 1758)	Lesser Whitethroat	O+L
Curruca melanocephala (Gmelin, 1789)	Sardinian Warbler	O+L
Curruca nisoria (Bechstein, 1795)	Barred Warbler	O+L
Sylvia atricapilla (Linnaeus, 1758)	Eurasian Blackcap	O+L
Sylvia borin (Boddaert, 1783)	Garden Warbler	L
Turdidae		
Turdus merula Linnaeus, 1758	Eurasian Blackbird	O+L
Turdus philomelos Brehm, 1831	Song Thrush	L
Strigidae		
Athene noctua (Scopoli, 1769)	Little Owl	O+L
Asio otus (Linnaeus, 1758)	Northern Long-Eared Owl	L
Otus scops (Linnaeus, 1758)	Eurasian Scops-Owl	L
Strix aluco Linnaeus, 1758	Tawny Owl	L
Tyto alba (Scopoli, 1769)	Common Barn-Owl	L

** O: Observed, L: Literature*

Among the bird species detected in the Project Area and its immediate surroundings, those that are found to have a natural distribution within the Project Area are endemic, rare or endangered according to IUCN (CR: Critical; EN: Endangered; VU: Vulnerable), When considering a species included in the Bern and CITES conventions and Habitat Directive, monitoring of *Streptopelia turtur* (VU) and *Neophron percnopterus* (EN) is recommended. It is essential to assess the population status of these species in the Project Area, along with factors such as habitat use, feeding, and other bioecological characteristics, to evaluate the potential impacts of the Project activities. Birds in and around the Project Area populations have been assessed as “Low” and “Moderate” on a species base. Relative abundance and presence of species for birds is given in Table IX.18

Table IX.18 Relative Abundance and Presence of Species for Birds

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)
Birds	*Neophron percnopterus*	Low	N
	Streptopelia turtur	Low	Y
	Accipiter nisus	Low	Y
	Aquila chrysaetos	Low	N
	Buteo buteo	Low	Y
	Buteo rufinus	Low	Y
	Circaetus gallicus	Low	Y
	Circus aeruginosus	Low	Y
	Circus cyaneus	Low	N
	Circus macrourus	Low	N
	Ciconia ciconia	Low	Y
	Ciconia nigra	Low	N
	Falco columbarius	Low	N
	Falco peregrinus	Low	N
	Falco subbuteo	Low	N
	Falco tinnunculus	Low	Y
	Other bird species	Moderate	Y

Transition Routes within the Project Area and Its Surroundings

Ornithological monitoring studies conducted in the Project Area and its immediate surroundings, along with previous monitoring studies in nearby areas and literature reviews, have identified that migratory species such as the White Stork (*Ciconia ciconia*), Black Stork (*Ciconia nigra*), and Egyptian Vulture (*Neophron percnopterus*) pass over the region during migration periods. Both the bird migration route map and field observations have determined that the region is not located on any significant bird migration route (Figure IX.24).

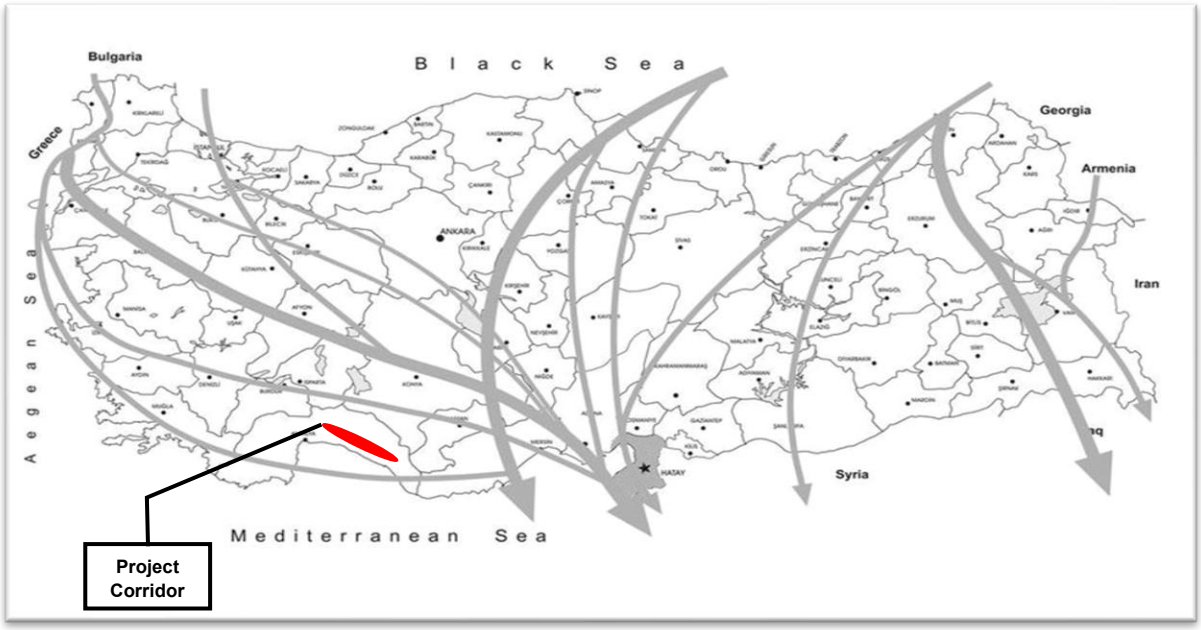

Figure IX.24 Bird migration routes map of Türkiye

IX.5.3.4. Mammals

While creating a table of mammal species found in the area, the existing fauna along with the natural ecosystem features of the area are listed. Because vertebrate animals, thanks to their ability to move, can occasionally enter and exit areas that have acquired anthropogenic characteristics, and even adapt. The Project Area and its surroundings are covered with steppe vegetation. Considering its zoogeographical location and habitat characteristics, the area hosts large mammal species in addition to common rodent species. It has been observed that the Project Area is not suitable for nesting and breeding of large mammal species due to its proximity to agricultural lands and anthropogenic activities.

As a result of observations and interviews in the field, it was determined that there was a possibility of a total of 46 mammal species belonging to 17 families from five orders in the Project Area and ecological impact areas. The table of mammal species found and likely to be found in the Project Area and its immediate surroundings, along with their conservation status, is presented in Annex 10, Table 9.8.

As a result of mammal observations and literature searches along the Motorway route, nearly half of the species (20 species; 43.5%) of the identified species belong to the order Chiroptera (bats), followed by Rodentia (12 species; 26.1%), Carnivora (nine species; 19.6%), Cetartiodactyla and Eulipotyphla (two species each; 4.3%), and Lagomorpha, represented by a single species (Figure IX.25).

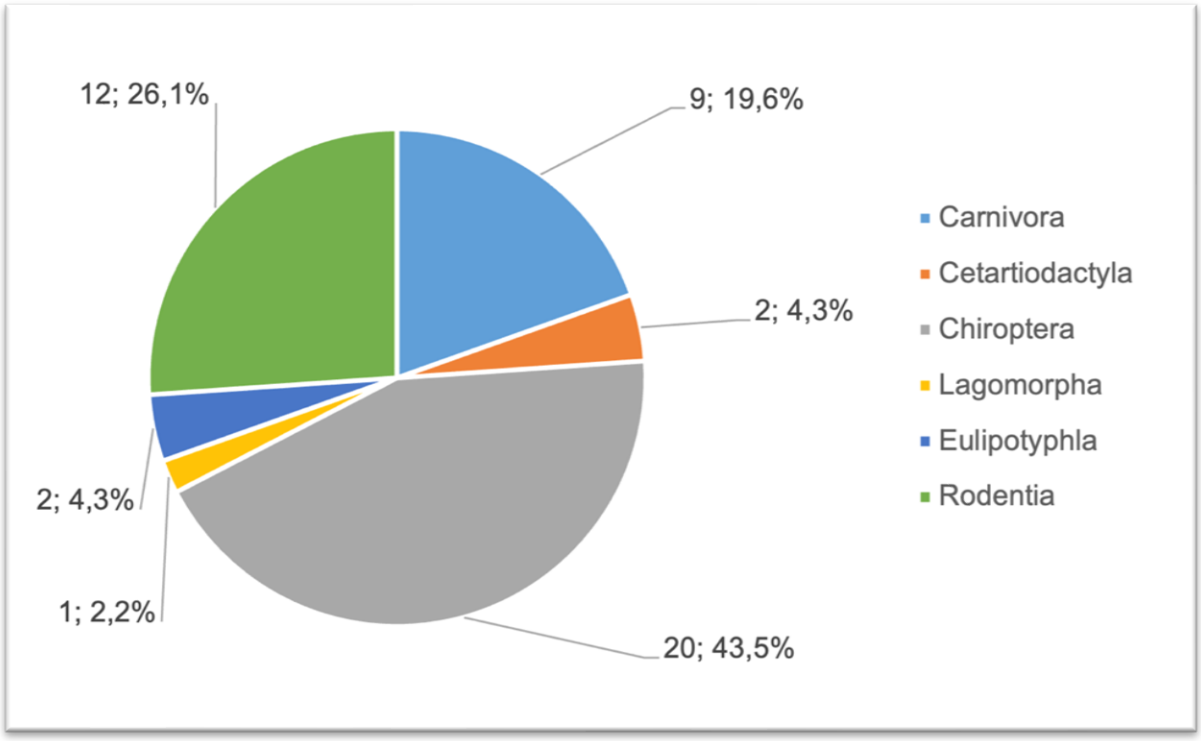

Figure IX.25 Distribution of number of mammal species based on orders

When the distribution of species according to families is examined, Vespertilionidae is the most dominant family with 13 species (28.3%), followed by Muridae (six species; 13.0%), Rhinolophidae and Mustelidae (five species each; 10.9%), Canidae (three species; 6.3%), and Sciuridae and Cricetidae (two species each; 4.3%). The remaining 10 families are represented by one species each.

Photographs of some of the mammal species observed during the monitoring studies carried out in and around the Project Area and as a result of the monitoring studies carried out in and around the site in the past are given in Annex 10.

Field surveys for bats should focus on caves, tree hollows, abandoned buildings, and agricultural structures near the Project Area, as these sites may serve as potential roosting locations for bats.To assess bat diversity, detectors (batcorder) were deployed at night along the motorway route, and the recorded bat calls were analyzed. Some bat calls in the phylogenetic tree analysis lacked sufficient distinguishing characteristics, preventing species-level identification. However, frequency analysis confirmed the presence of three bat species in the area: *Pipistrellus kuhlii*, *Pipistrellus pipistrellus*, and *Rhinolophus ferrumequinum*.

Among the 46 mammal species with potential distribution in the area, according to IUCN conservation statuses, two species are classified as VU (*Rhinolophus mehelyi* and *Myotis capaccinii*), four species as NT, two species as DD, one species as NE, and the remaining 37 species are classified as LC. Considering the identified species, it has been determined that the area is not used specifically by mammal species to meet their biological needs such as breeding, feeding, or wintering.

Among the mammal species that are likely to be encountered in the area, 30 species are included in the Bern Convention lists. Of these, 24 species are listed in Appendix II and six species are listed in Appendix III.

According to the EU Habitat Directive, 11 of the 46 mammal species identified in the Project Area and its immediate vicinity are listed in Appendix II. Among those listed in Appendix II, 10 species are also listed in Appendix IV, and one species is listed in Appendix V. Additionally, 13 species are listed in Appendix IV, and one species is listed in Appendix V.

Among the mammal species that are likely to be encountered in the area, according to CHCD, two species are listed in Annex-I (Game Animals Protected by CHCD) and 8 species are listed in Annex-II (Species Allowed to Hunt in Certain Periods).

The field survey conducted in the area identified mammal species with potential distributions previously reported in the literature; however, no endemic species were recorded. Nevertheless, *Capra aegagrus*, a non-endemic but rare species, was documented in the region. Given that this species primarily inhabits rocky terrains, its occurrence within the study area is considered incidental, with only occasional sightings. The relative abundance for mammal species except for bats is assessed as “Moderate”, which roughly estimates as 20-100 individuals. More details regarding this can be found in section IX.7. Observed sampling points and observation method for mammals is given in Table IX.19, fauna sampling points are given in Figure IX.2.

Table IX.19 Observation Method, and Species Presence in Sampling Points for Mammals

Scientific Name	Observation Method	Species Presence in Sampling Points
Canis Aureus Linnaeus, 1758	O+L	All Fauna Sampling Points

	Rhinolophus mehelyi	Low	N
	Other bat species	Moderate	Y

IX.5.3.5. Terrestrial Invertebrate

A comprehensive terrestrial invertebrate desk study has been conducted for the Project area, drawing on up-to-date national and international databases, peer-reviewed literature, and relevant grey

literature sources. The assessment identified a total of 139 species that are potentially present within the Project's impact area. Among these, two species, *Onychogomphus assimilis* and *Brachythemis fuscopalliata*, are classified as Vulnerable (VU) on the IUCN Red List, with *Brachythemis fuscopalliata* also listed in Annex II of the Bern Convention, highlighting its international conservation importance. The taxonomic composition of the species indicates that Lepidoptera dominate the assemblage, with 102 species recorded, followed by Odonata with 33 species and Diptera with three species.

The prominence of Odonata is particularly significant, as species in this order are widely recognized as reliable indicators of wetland habitat quality and hydrological integrity. These findings suggest that wetland and riparian habitats along the Motorway route support a sensitive and functionally important invertebrate community. The presence of conservation-listed species and the high proportion of wetland indicator taxa underscore the need for targeted avoidance, minimization, and habitat management measures during construction, including preservation of riparian buffers, careful planning of watercourse crossings.

In the study, due to a lack of habitat suitability for two "VU" species, it was determined that there's no need for terrestrial invertebrate monitoring.

IX.5.4. Aquatic Environment

During habitat assessments, parameters such as existing cover, burial characteristics of ground stones, substrate characteristics of standing water environments, flow velocity, depth, structure of standing water environments, sedimentation, bottom cover of streams/creeks, variability of the river bottom, geomorphological condition of the river bottom, stability of the river banks and vegetation cover of the river banks will be considered. After all field studies are completed, aquatic habitat assessment will be carried out with the data obtained.

Freshwater Algae

Algae communities generally have relatively rich species diversity compared to other aquatic groups. Each species has its unique tolerance and preferences for environmental factors. Thus, the whole association offers a wealth of information for environmental indicators.

As a result of the literature studies and field observation studies, it was determined that there was no need for a sampling study for the detection of algae.

Zooplanktonic Organisms

Zooplanktonic organisms are mostly displaced by the movement of water and live in stagnant water habitats. Their availability in fast flowing parts of streams is very limited. However, in some groups, they can be seen as psammophiles, that is, as species that can live under stones in fast-flowing streams. Species belonging to the Rotifera group often utilize rocky substrates, which help mitigate the adverse effects of current velocity.

Zooplanktonic organisms, like phytoplankton, prefer stagnant environments with little flow. Zooplanktonic organisms must be fed with phytoplanktonic organisms in order to continue their development. Therefore, they prefer areas where this nutrient is abundant and other physical and chemical factors are optimum for them. Rivers and streams are not suitable habitats for these organisms. In these areas, the phytoplanktonic organisms they use as food are low, and the river current is an important limiting factor. Due to their very small size, they can easily be dragged to death. For this reason, it was determined that there is no need for sampling of zooplankton.

Benthic Invertebrates

Benthic organisms are among the preferred groups in biological monitoring studies due to their stated characteristics (Rosenberg and Resh, 1992). Some of the reasons benthic organisms are preferred in such a study are as follows.

- Although there are many different environments in aquatic systems, they have adapted to every environment.
- A wide variety of species groups respond across a broad spectrum, depending on the severity of environmental pressure.
- It generally depends on the areas where it is located. They cannot escape from environmental change and polluting effects.

Literature studies suggest that benthic organisms are important in determining pollution in aquatic environments. In the field study, it was determined that there is no need for benthic invertebrates monitoring.

Fishes

Throughout the route of the Motorway route, there are temporary or permanent streams. These streams originate from the Taurus Mountains and flow into the Mediterranean. Due to the route's proximity to the sea, both freshwater and marine fish are present in these streams. In a study by Küçük and İkiz (2004) on the fish fauna of streams flowing into the Antalya Gulf, 24 species from 12

families were reported. Some of these species were recorded from streams outside the Motorway route.

In a study conducted by İnnal (2012) in the lower reaches of the Köprüçay River, 23 species were identified, with half of them being marine fish. Küçük&Friends (2020) reported 20 taxa from nine families in the Manavgat River as part of a study examining changes in the fish fauna over a 25-year period from 1995 to 2020. "Field surveys identified 20 species from seven families. Thus, based on both literature data and fieldwork, information on 30 fish species from 10 orders and 16 families identified in the Project Area is provided in Table 9.3 in Annex 10.

In the field studies conducted for the project, 29 species from seven families were identified. Based on field studies and literature reviews of aquatic ecosystems along the motorway route, it has been determined that half of the identified species (14 species, 48.3%) belong to the Cypriniformes order, followed by Mugiliformes with 13.8% (four species), and Salmoniformes and Cyprinodontiformes with 6.7% each (two species). The remaining orders are represented by a single species each (Figure IX.26).

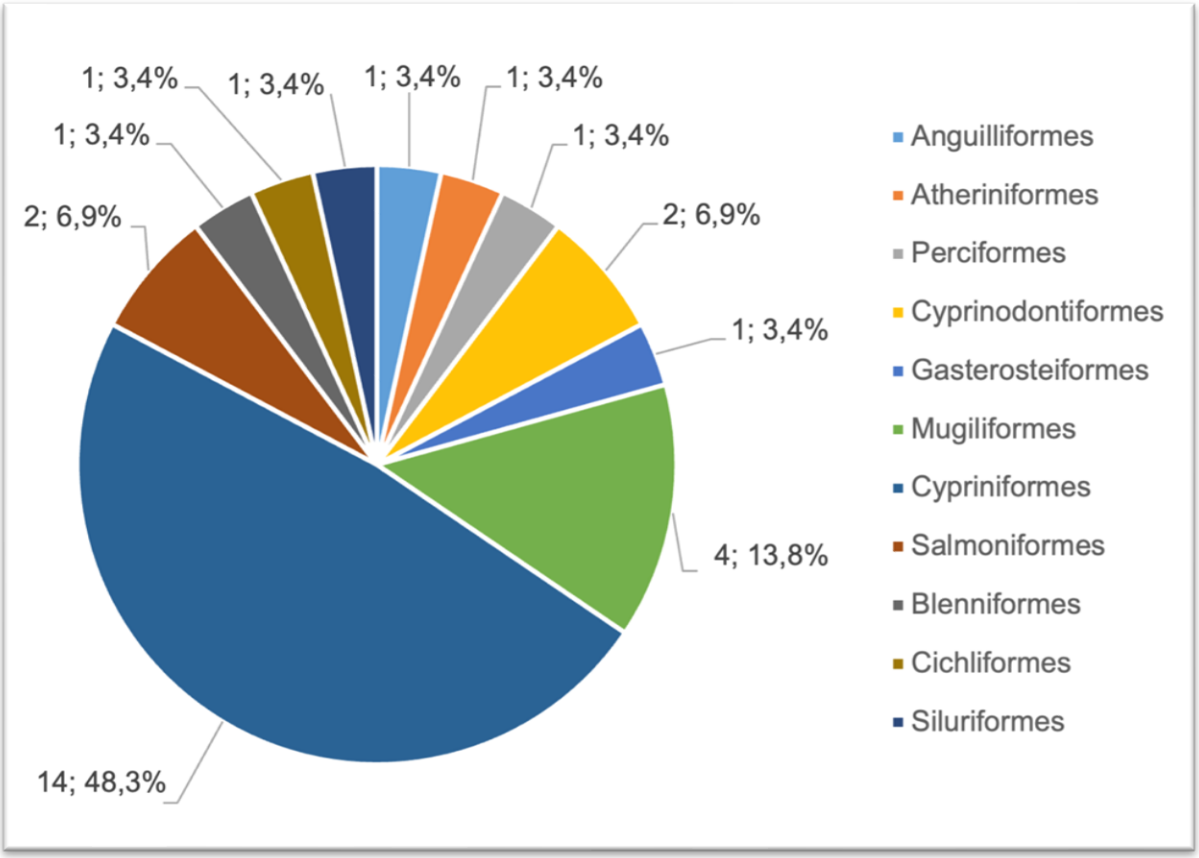

Figure IX.26 Distribution of Number of Fish Species based on Orders

When examining the distribution of species by family, Leuciscidae is the most dominant family with seven species (24.1%), followed by Cyprinidae and Mugilidae, each with four species (13.8%). The Salmonidae family has two species (6.9%). The remaining families are each represented by one species. Photographs of the species encountered during field studies are presented in Annex 10. The locations of the fish observation stations determined during aquatic ecosystem sampling studies are presented in Table 9.4 in Annex 10.

Photographs of some of the identified fish species observed during the monitoring studies carried out in and around the Project Area are given in Annex 10.

According to IUCN criteria, there are six species that are endangered or near-threatened (CR:Critical; EN: Endangered; VU: Vulnerable). Among the 29 species, *Anguilla anguilla* is listed in Appendix II of the CITES Convention, whereas no species have been recorded in the additional appendices of the Bern Convention in relation to the Project Area..

The *Anguilla anguilla* (CR), which is considered endangered, is an anadromous species and grows and develops in streams and reproduces in Sargossa Bay. Project activities are not expected to have any impact on this species. *Cyprinus carpio* (VU), which is considered to be under threat, was evaluated by IUCN considering the European populations. The species in question is used for fish farming in many aquatic ecosystems in Türkiye and is one of the most commercially caught species. For this reason, it is not recommended to monitor both species.

According to the CITES Convention, among the fish species identified in the Project Area and its immediate surroundings, only *Anguilla anguilla* is listed in Appendix II.

Among the 29 fish species identified in the Project Area and its immediate surroundings, none are listed under the Bern Convention.

According to the Habitats Directive, none of the fish species identified in the Project Area and its immediate surroundings are listed.

Among the fish species encountered in the area, there are species listed under the Central Hunting Commission Decisions (CHCD). These species, like other fish species in the country, are considered to be under protection by the Ministry of Agriculture and Forestry.

There are 11 endemic species among the fish species identified in the Project Area and its immediate surroundings. These species are distributed in the rivers in the Project Area as well as in regions outside this area. In addition, some species (*Salmo ekmekciae*) are distributed in certain sections of the stream, not in the entire stream. 29 fish species are listed in the list created based on literature and field work. For this reason, it is not possible for all species to be distributed in the Project Area. Among these species, there are no local endemic species that are distributed only in the Project Area.

As a result of the field studies, considering the species in both endemic and threatened categories, it has been observed that the area where activities will be carried out within the scope of the Project Area and determined as the impact area does not exhibit an essential and critical habitat feature for the species in question.

However, it was concluded that it is necessary to monitor endemic species declared to be endangered during the construction of the Project. For this reason, the existence and population status of three species, namely *Capoeta antalyensis* (VU), *Alburnus baliki* (EN) and *Pseudophoxinus fahrettini* (EN), should be monitored once a month with field work between May and August.

Species observation location for fishes is given in Table IX.21 and locations for stations is given in Figure IX.1. While relative abundance and species presence is given in Table IX.22.

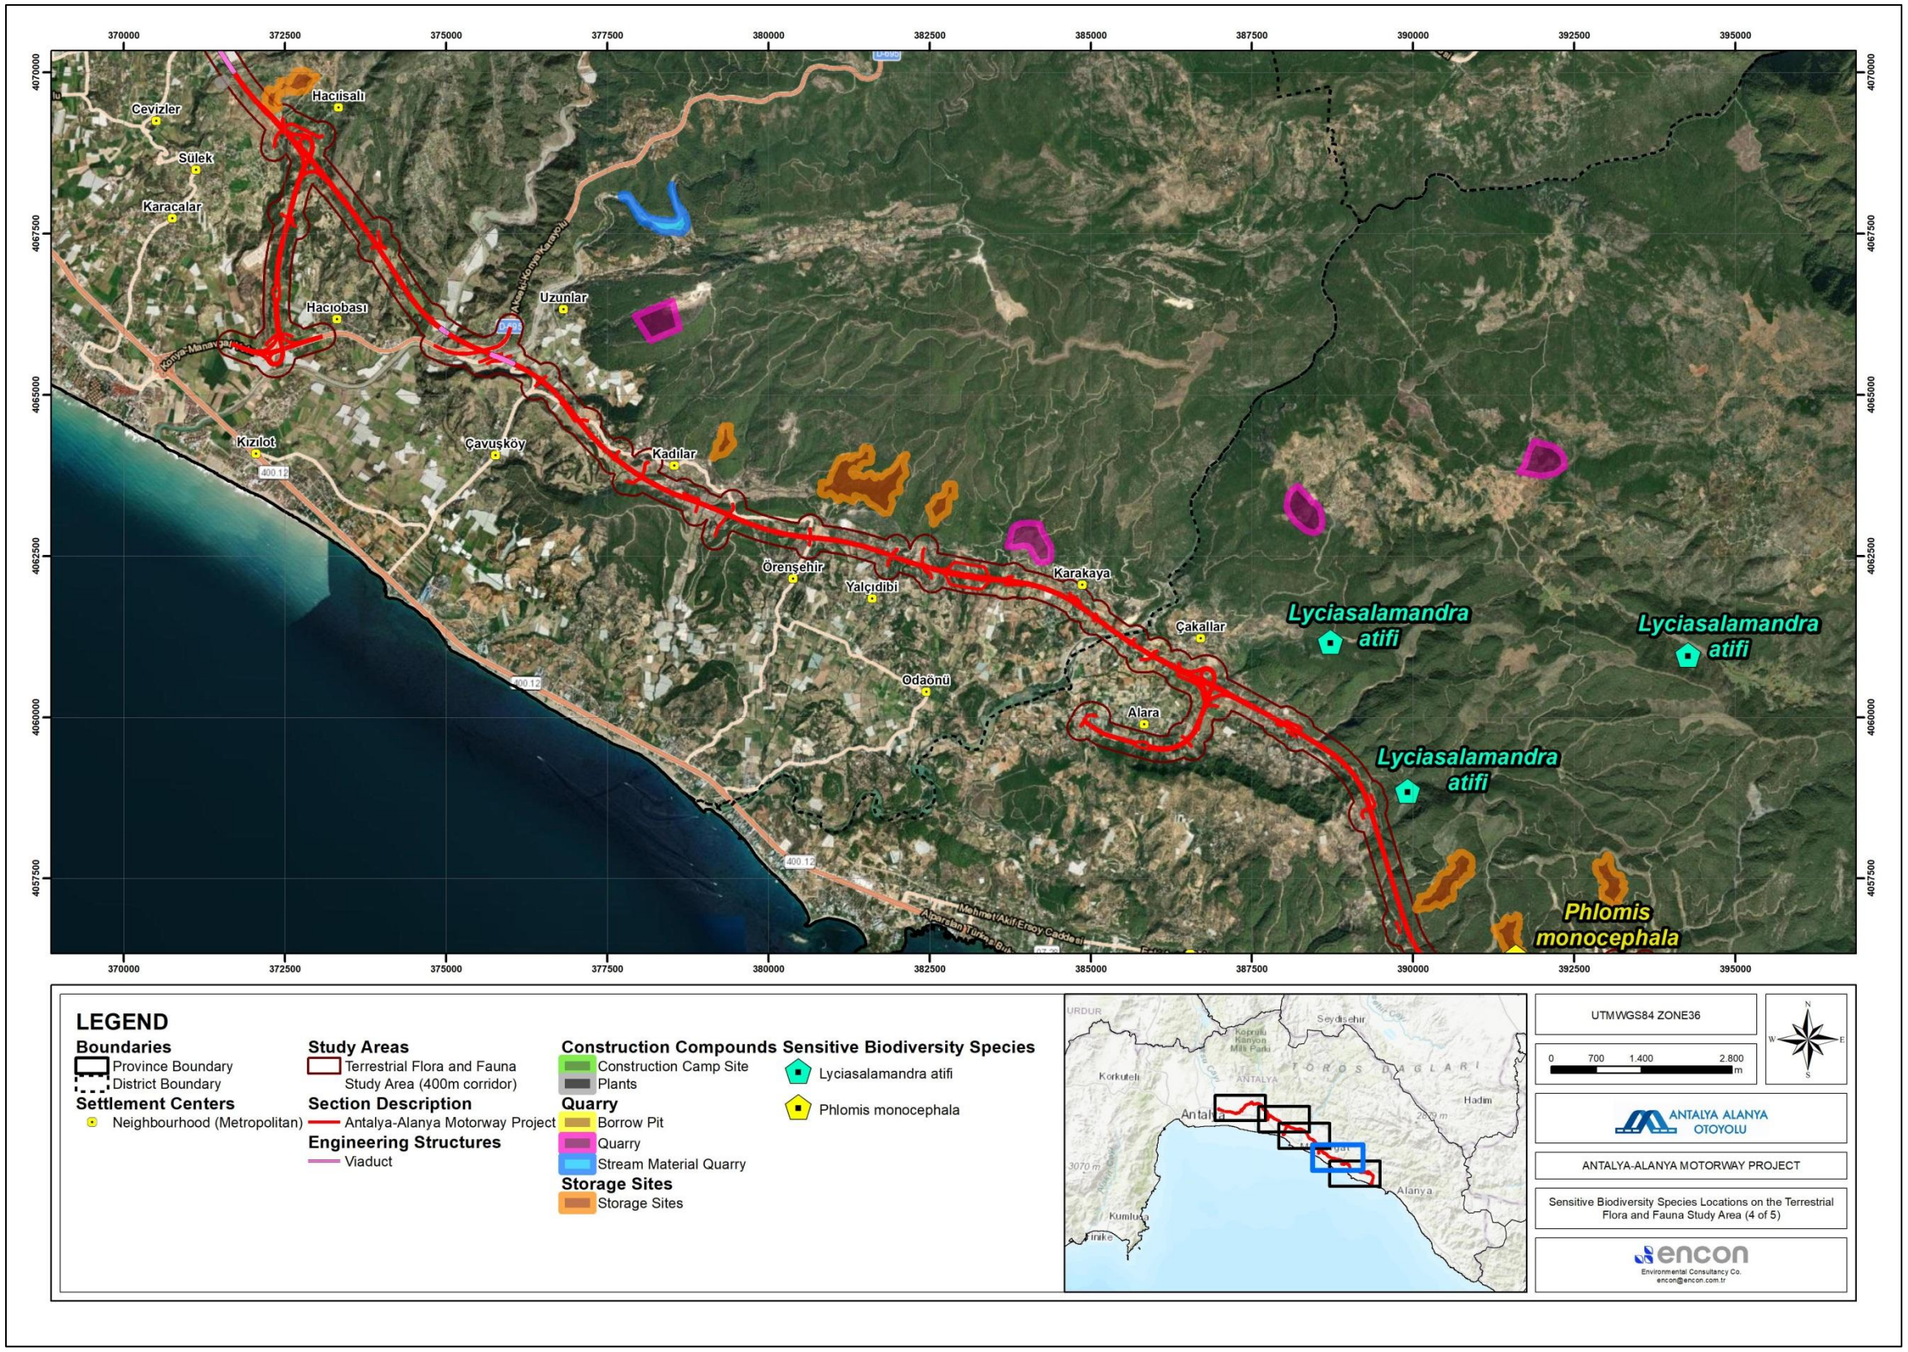

Figure IX.30 Locations of Sensitive Biodiversity Flora/Fauna (4/5)

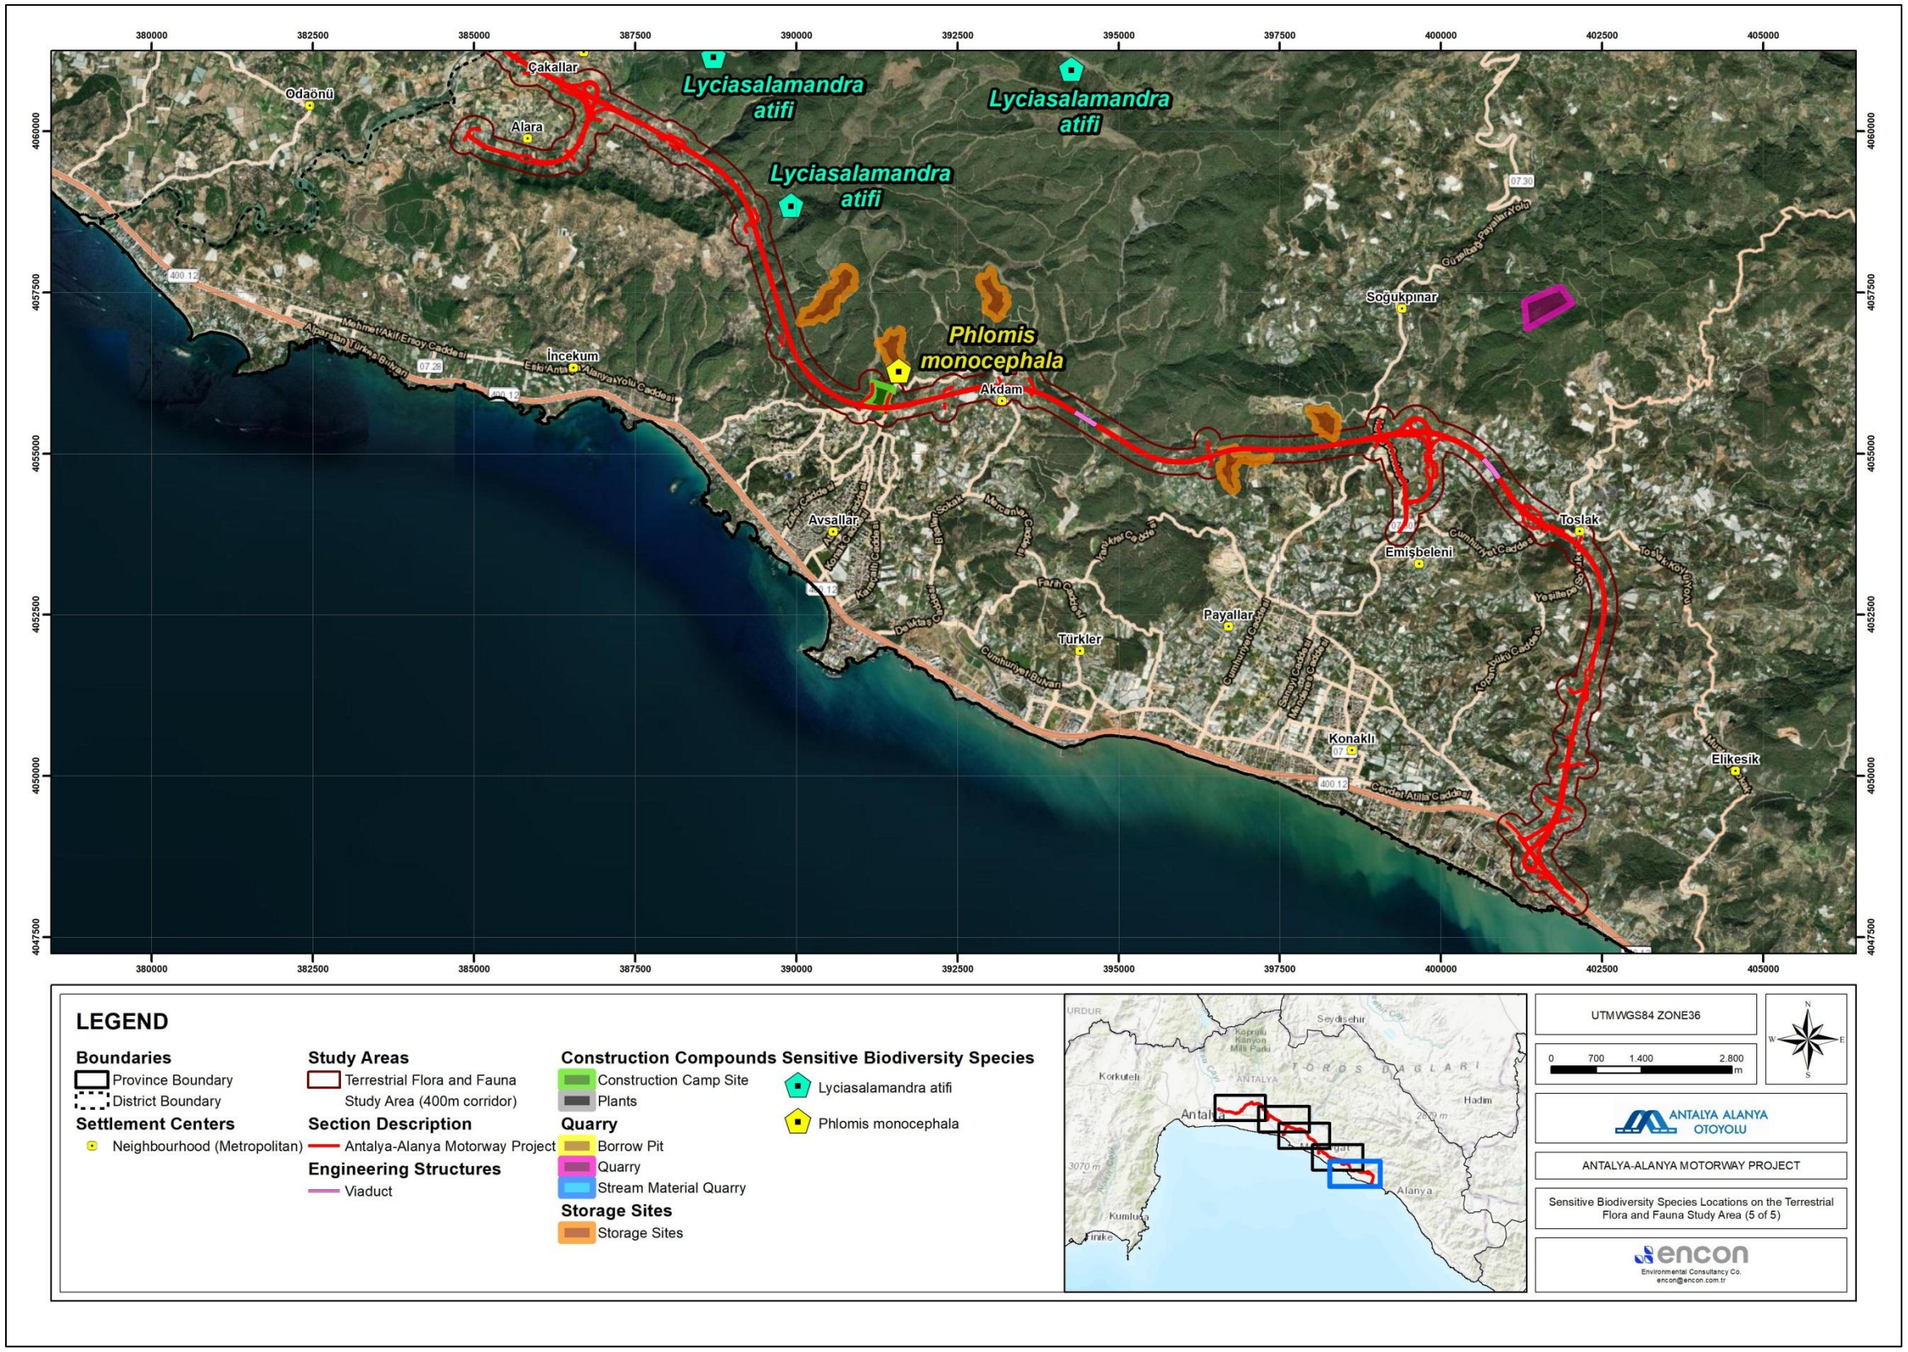

Figure IX.31 Locations of Sensitive Biodiversity Flora/Fauna (5/5)

IX.5.6. Invasive Species

No invasive plant, amphibian, reptile, bird, or mammal species were detected within the Project Study Area. The only invasive species recorded were freshwater fish species. These species are:

- *Pseudorasbora parva*
- *Oncorhynchus mykiss*
- *Carassius gibelio*
- *Oreochromis aureus*

Mitigation measures in accordance with IFC standards will be implemented to manage all invasive species identified within the project area or introduced to the site. Additionally, preventative actions will be undertaken to avoid the introduction and further spread of these species into the surrounding environment.

IX.6. Critical Habitat Assesment

To assess the potential presence of Critical Habitat, an Ecologically Appropriate Area of Analysis (EAAA) was prepared for each species. This analysis considers the species' distribution—both within and, where applicable, beyond the Project's Area of Influence—as well as the ecological processes, features, and functions essential to the species' persistence. The boundaries of each species-specific EAAA may encompass catchments, major river systems, or relevant geological features. These defined EAAAs are intended to provide a functional basis for evaluating the applicability of Critical Habitat criteria and associated thresholds.

More detailed information on critical habitat analysis and evaluations is provided in the standalone Critical Habitat Assessment (CHA) report.

C1: Critically endangered and/or endangered species

For Criterion-1, species classified as Critically Endangered (CR) or Endangered (EN) under the IUCN Red List were assessed. Where global assessments were unavailable (e.g., Not Evaluated or Data Deficient), national sources such as the Turkish Red Data Book were used. An expert reviewed and updated threat statuses using the most recent data on species distributions.

Out of 221 plant taxa recorded in the region, only *Pyrus serikensis* (EN) meets the IUCN threat criteria. This species is found within the maquis ecosystem near the Serik district. As it is estimated to represent at least 5% of the extent of occurence, the area qualifies as critical habitat under Criterion-1. Accordingly, maquis habitats along the project route have been designated as critical habitat.

Among five amphibian species identified, *Lyciasalamandra atifi* (EN) has not been observed within the Project Area. However, due to its secretive nature and seasonal activity, its absence cannot be definitively confirmed. Although the species has been observed in suitable areas (EAAA) at higher altitudes outside the Project Area, these potential habitats have not been classified as critical habitats because the species has not been observed in the study area and the possible EAAA do not overlap with the Project Area. As it typically occupies higher elevations, continued monitoring is recommended. If future surveys confirm its presence, relevant areas will require critical habitat designation.

Bird diversity is high, with 124 species recorded. *Neophron percnopterus* (EN) was identified but does not meet Criterion-1 thresholds for critical habitat designation based on regional assessment (EAAA).

Of 29 fish species recorded from 10 orders and 16 families, three are listed as threatened: *Anguilla anguilla* (CR), *Alburnus baliki* (EN), and *Pseudophoxinus fahrettini* (EN).

Species classified as Vulnerable (VU) are broadly distributed and are not expected to meet the Criterion-1 thresholds for critical habitat designation.

A summary of species evaluated under Criterion-1 is presented in Table IX.23. Species considered to potentially trigger critical habitat—based on literature records or insufficient field data—are categorized as Potential Critical Habitat. Conversely, where the presence of a qualifying species has been confirmed through direct observation, the area is designated as Critical Habitat.

Table IX.23 Critical Habitat Assessment According to Criterion-1

Species	IUCN	EAAA > 0.5% EOO	Criteria Assessment	Critical Habitat Assessment
Pyrus serikensis	EN	yes	Cover C1. Distribution areas have been determined as critical habitat.	CH
Lyciasalamandra atifi	EN	yes*	Monitoring should continue to determine the presence of the species in the Project Area.	PCH
Neophron percnopterus	EN	no	Not trigger C1	Not Critical Habitat
Anguilla anguilla	CR	no	Not trigger C1	Not Critical Habitat
Alburnus baliki	EN	no	Not trigger C1	Not Critical Habitat
Pseudophoxinus fahrettini	EN	no	Not trigger C1	Not Critical Habitat

* EAAA of *Lyciasalamandra atifi* does not overlap with the Project Area

C2: Endemic and/or restricted-range species

The Criterion-2 assessment focuses on the presence of endemic or restricted-range species. These are defined as having an extent of occurrence (EOO) less than 50,000 km² for terrestrial vertebrates and plants, or a global range of 500 km or less in linear extent for aquatic species not exceeding 200 km in width at any point.

A total of 221 plant taxa from 60 families were recorded within the Project Area. Among them, seven species are endemic to Türkiye: *Eryngium kotschyi*, *Phlomis leucophracta*, *Phlomis lycia*, *Phlomis monocephala*, *Phlomis nissolii*, *Pyrus serikensis*, and *Sideritis congesta*. Except for *Pyrus serikensis*, these endemic species have relatively wide distributions. *Pyrus serikensis* is not estimated to represent 10% of its global population within the maquis habitats along the project route, thereby does not meet Criterion-2.

Five amphibian species were recorded, with *Lyciasalamandra atifi* being the only endemic species. Although not observed within the Project Area during spring surveys, its presence in nearby suitable habitats suggests potential occurrence. Given its specific ecological requirements and the dry, mild conditions during surveys, its absence may not be definitive. Continued monitoring is recommended. If confirmed, the species may qualify the area as Critical Habitat under Criterion-2.

Lyciasalamandra atifi is highly sensitive to changes in hydrological and climatic conditions, which are key factors in its Endangered status. Its seasonal and habitat-specific activity patterns make early spring the most appropriate time for further surveys.

Among reptiles, four endemic lizard species were identified: *Ablepharus anatolicus*, *Anatololacerta ibrahimi*, *Lacerta pamphylica*, and *Blanus aporus*. While *Lacerta pamphylica* has a relatively narrow distribution and is present within the Project Area, none of these species are considered to trigger Criterion-2 due to the scale of their population representation in the area.

Of the 29 fish species identified, 11 are endemic, including *Capoeta antalyensis*, *Pseudophoxinus battalgilae*, and *Pseudophoxinus fahrettini*, which are more regionally confined. However, no species meets the Criterion-2 thresholds for population concentration along the project route. Therefore, no Critical Habitat has been designated for fish species under this criterion.

A summary of the evaluation of species falling under Criterion-2 is provided in Table IX.24.

Table IX.24 Critical Habitat Assessment According to Criterion-2

C3: Habitats supporting globally significant migratory or congregatory species

This assessment considered the presence of Key Biodiversity Areas (KBAs), Important Bird and Biodiversity Areas (IBAs), and Ramsar Wetlands of International Importance (criteria 5 or 6), with a focus on migratory and congregatory species.

Within the Project Area, the Antalya Plains (KBA/IBA) is the only internationally recognized site of biodiversity importance. Species that qualify this KBA/IBA (*Halcyon smyrnensis* and *Prinia gracilis*) were not observed in surveys conducted in the project study area and its surroundings.

No migratory or herd-forming species were identified among the amphibians, reptiles, or mammals recorded in the Project Area. Therefore, no critical habitat has been designated for these taxa under Criterion-3.

Although the Project Area does not lie along a primary or secondary migration corridor for soaring birds in the Mediterranean, both field observations and BirdLife International data confirm the presence of 20 soaring bird species in the area. However, their observed population densities are below the thresholds required to trigger Criterion-3. As a result, no critical habitat has been designated for avian species.

The European eel (*Anguilla anguilla*), a catadromous fish species, is known to occur in rivers within the Project Area, which flow into the sea. While *A. anguilla* meets the general definition of a migratory species, it does not fulfill either of the specific sub-criteria required to trigger Criterion-3. Therefore, no critical habitat has been designated for this species.

A summary of the evaluation of species falling under Criterion-3 is provided in Table IX.23.

Table IX.25 Critical Habitat Assessment According to Criterion-3

Species	IUCN	EAAA > 1% EOO	Criteria Assessment	Critical Habitat Assessment
Accipiter nisus	LC	no	Not trigger C3	Not Critical Habitat

Falco peregrinus	LC	no	Not trigger C3	Not Critical Habitat
Falco subbuteo	LC	no	Not trigger C3	Not Critical Habitat
Falco tinnunculus	LC	no	Not trigger C3	Not Critical Habitat
Anguilla anguilla	CR	no	Not trigger C3	Not Critical Habitat

C4: Highly-threatened and unique ecosystems

Criterion-4 recommends the use of the IUCN Red List of Ecosystems (RLE) where available. However, no formal RLE assessments have been conducted in Türkiye, as confirmed by the IUCN RLE Database. In the absence of national RLE data, the European Red List of Habitats (EU, 2016) was used as an alternative framework to assess ecosystem threat status.

None of the habitats identified within the Project Area are listed as priority habitats under Annex I of the EU Habitats Directive or recognized as threatened in the European Red List of Habitats. Additionally, none of the EUNIS-classified habitats identified through photointerpretation, mapping, and field validation are categorized as Critically Endangered (CR) or Endangered (EN), nor are they considered unique ecosystems. Expert evaluations also did not report any unique or threatened habitats within the Local Study Area (LSA).

River crossings along the motorway route will be implemented via bridges, with impacts expected to be temporary and limited to the construction phase. Mitigation measures will be employed, and no significant or lasting impact on river ecosystems is anticipated.

The Project Area is located along Türkiye's Western Mediterranean Coast. The corridor lacks habitat characteristics essential for supporting the biological needs—such as breeding, feeding, or wintering—of endemic, rare, or threatened species.

In conclusion, the Project Area does not contain any ecosystems that meet the criteria for unique or threatened ecosystems under Criterion-4.

C5: Key evolutionary processes

Criterion-5 evaluates areas with landscape features that support ecological and evolutionary processes, such as those promoting genetic diversity, adaptation, or long-term species persistence. This includes habitats with high spatial heterogeneity, edaphic transitions, or areas of significance for climate change adaptation.

Within the Project Area, no landscapes with high spatial heterogeneity, edaphic interfaces, or recognized significance for climate adaptation were identified. Additionally, the area is not considered a biological corridor nor of proven importance for evolutionary processes.

Based on current data and expert input, the habitats within the Study Area do not meet the conditions outlined under Criterion-5. Therefore, no critical habitat has been designated under this criterion.

IX.6.1. Summary of Critical Habitat Features

Based on the findings of the Critical Habitat Assessment carried out for the Project, the following features have been identified as meeting the criteria to be classified as Critical Habitat.

- *Pyrus serikensis* is in “Endangered – EN” category according to IUCN and found primarily within the maquis ecosystem surrounding the project area, with known populations located near the Serik district, thus meeting critical habitat assessment criteria. Maquis habitats where *Pyrus serikensis* is present along the project route have been designated as critical habitats.

- Amphibian species *Lyciasalamandra atifi* is in “Endangered – EN” category according to IUCN and meeting critical habitat assessment criteria. However, this species typically inhabits higher elevations and was not observed in the study area.

- Considering the overall distribution ranges of all endemic reptile species, there is no critical habitat within the project area as defined by critical habitat assessment criteria.

- No bird species meets critical habitat assessment criteria based on their population status. Considering the population densities of migratory bird species present in the area, it has been determined that their populations are not at a level that meets critical habitat assessment criteria. Consequently, no critical habitat has been designated for birds within the project area.

- Since the global population densities of the bat species are unknown and no significant populations were observed in the area, they do not meet critical habitat assessment criteria.

- Since no freshwater fish species meet the critical habitat assessment criteria, no critical habitat has been designated.

- Since only modified habitats occur within the portion of the Antalya Plains KBA/IBA intersecting the Project Area, the Project's impact on this protected area is considered minimal.

- Since only modified habitats occur within the portion of the Belek SEPA intersecting the Project Area, the Project’s impact on this protected area is considered minimal. Therefore no critical habitat has been designated.

- Since the intersecting parts of Köprüçay Basin is a very small portion and the impacts on these parts are expected to be minimal, no critical habitat has been designated.

Table IX.26. Critical Habitat Assessment Results

Criteria	Habitat /Species triggered
Criterion 1: Critically endangered and/or endangered species	Maquis, arboreal matorral, and thermo-mediterranean scrub (EUNIS code S5) • *Pyrus serikensis*

IX.6.2. Ecology of Species Triggering Critical Habitat

- ***Pyrus serikensis*** **(EN, Regional Endemic)**

Scientific Name: *Pyrus serikensis*
Common Name: Serik Pear
Family: Rosaceae

Pyrus serikensis is a deciduous tree species reaching up to 10–15 meters in height. It is characterized by ovate to broadly elliptic leaves with serrated margins and a smooth, glabrous upper surface. The flowers are white, five-petaled, and hermaphroditic, arranged in corymbs. Fruits are globose to subglobose pomes, generally smaller than those of cultivated pears, and turn yellowish-green when mature.

Figure IX.32 *Pyrus serikensis*

Habitat and Distribution: This species is endemic to southwestern Türkiye, primarily restricted to the Serik district in Antalya Province. It is typically found in mixed deciduous forest ecosystems, often in

rocky, limestone-rich soils at elevations ranging from 100 to 600 meters. *P. serikensis* favors areas with a Mediterranean climate characterized by hot, dry summers and mild, wet winters.

Ecology: As a wild relative of cultivated pears, *Pyrus serikensis* plays an important ecological role in maintaining genetic diversity within the genus Pyrus. It serves as a potential genetic resource for disease resistance and drought tolerance. Flowering occurs in early spring, with pollination facilitated by a range of insect species, primarily bees.

Conservation Status: Due to its narrow endemic range and habitat degradation caused by agricultural expansion, urbanization, and forestry activities, *Pyrus serikensis* is considered at risk. Its population is fragmented and declining. Conservation efforts are essential to protect its natural habitats and prevent further loss of genetic diversity within the genus.

This species is associated with the S5 - Maquis, arborescent matorral and thermo-Mediterranean scrub EUNIS habitat category.

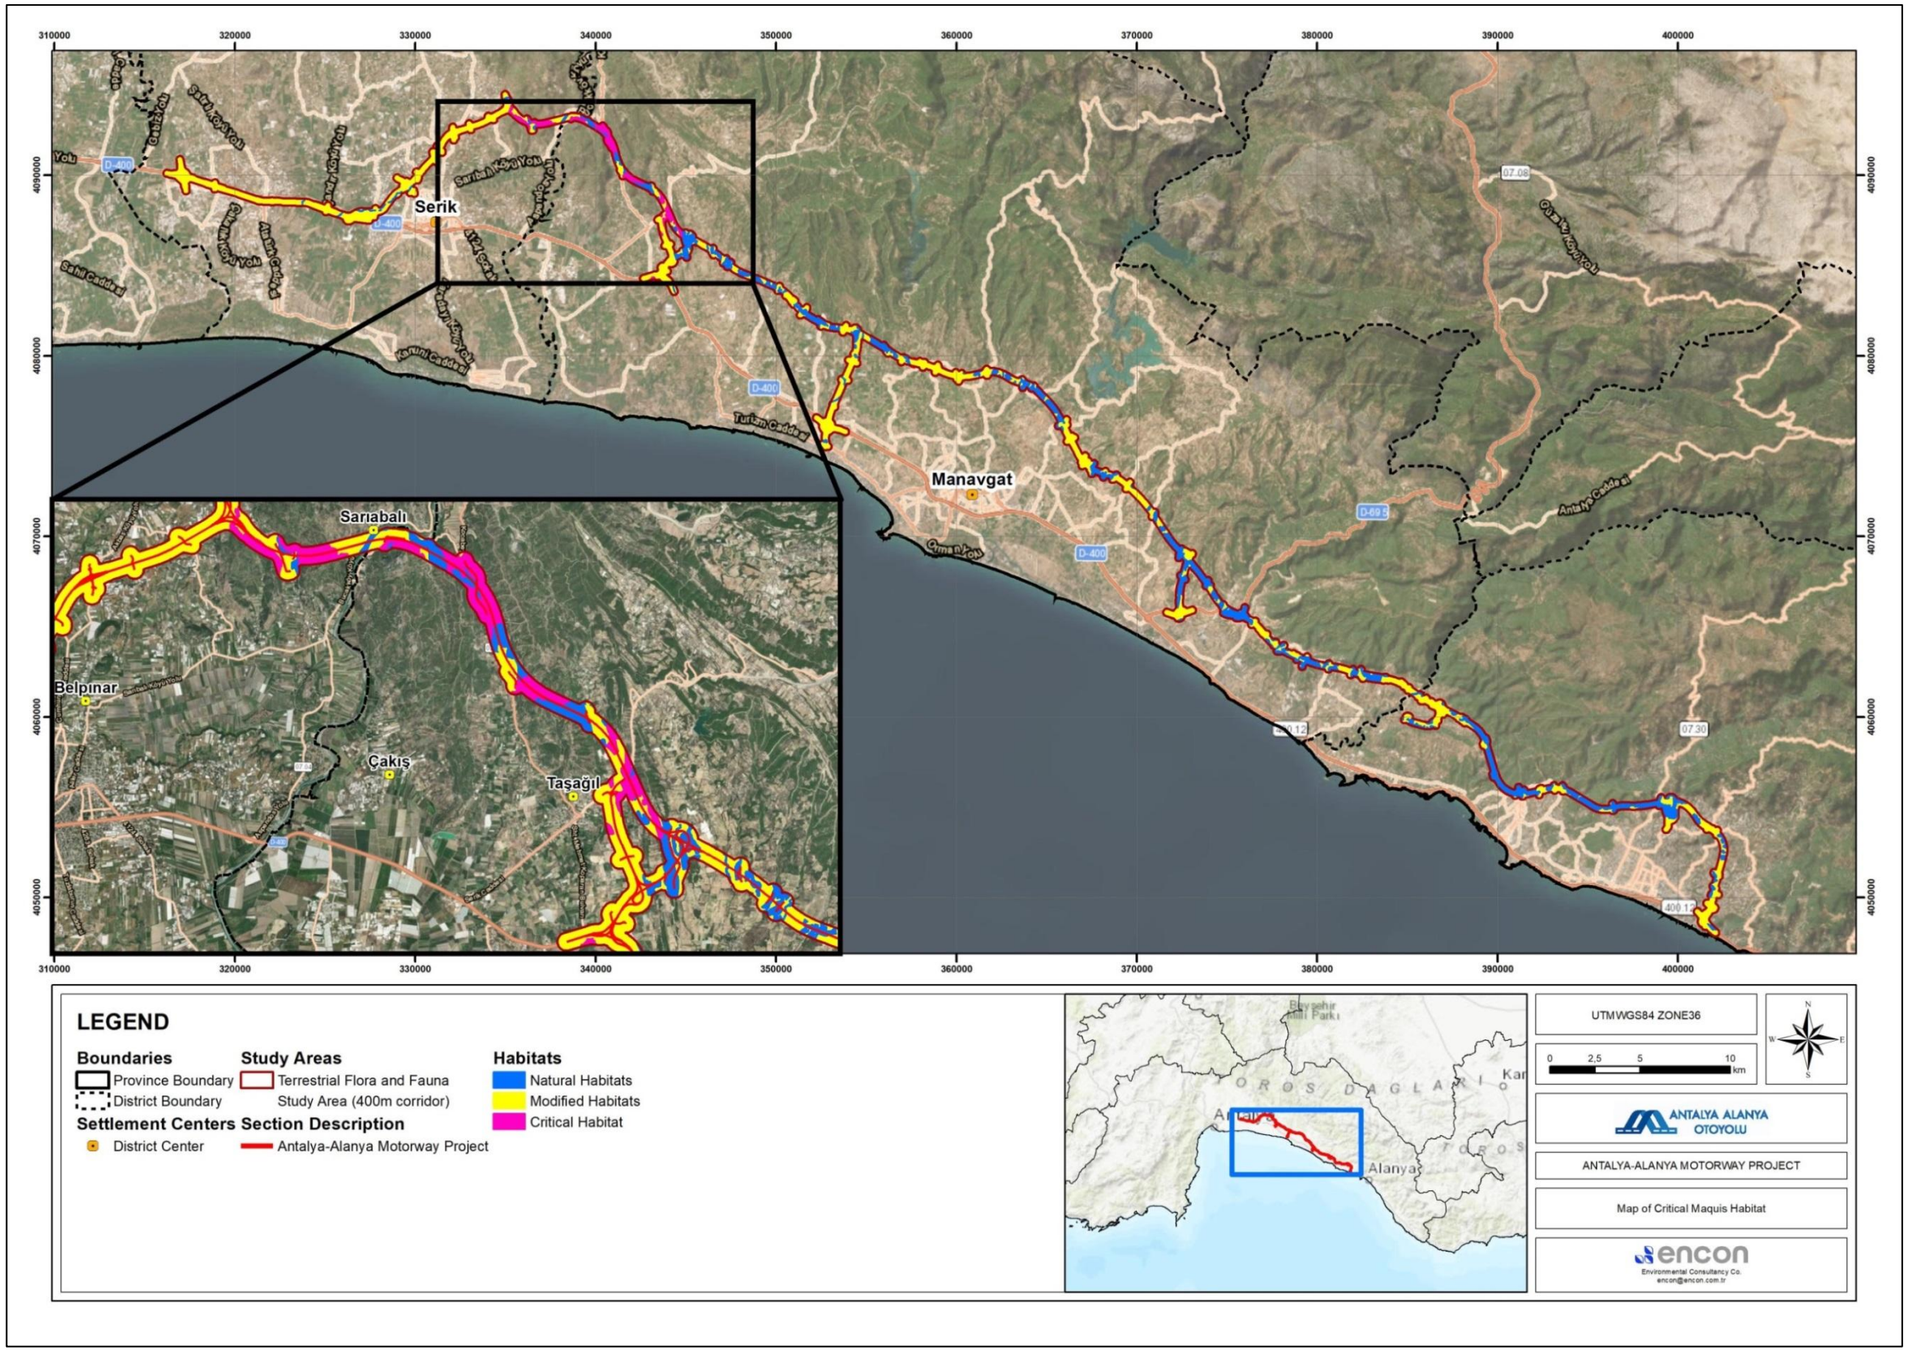

Figure IX.33. Critical, Natural and Modified Habitats in the Study Area

IX.1. Habitats and Species of Conservation Importance

As a result of the comprehensive assessments conducted during the biodiversity studies, the selection criteria for habitats and species to be addressed in the biodiversity conservation action plans - developed as part of this document- were defined as follows.

Species of conservation concern, for the purposes of this assessment, are defined according to the following criteria:

- Species classified as Critically Endangered (CR), Endangered (EN), or Vulnerable (VU) on the IUCN Red List;
- Species that are globally, nationally, or regionally threatened;
- Endemic species to the area;
- Species listed under Resolution No. 6 of the Bern Convention;
- Range-restricted species;
- Migratory species for which the local population represents more than 1% of the global population.

It is important to note that, as Turkey is not a member state of the European Union, Priority Biodiversity Features and Critical Habitat (CH) associated with the EU Habitats and Birds Directives are not applicable in this context.

The subsections below present the species of conservation concern identified as potentially occurring within the Study Area, based on the outcomes of the Environmental and Social Impact Assessment (ESIA) and according to the criteria outlined above.

Habitat types and species identified as having high priority and conservation importance listed in Table IX.27. The conservation of these species required specific actions to be implemented within the scope of the Project.

Table IX.27. Priority habitats and species of conservation importance

Biodiversity Component		Status
Habitat	Maquis, arboreal matorral, and thermo-mediterranean scrub (EUNIS code S5)	Critical Habitat
Species	*Pyrus serikensis*	Regional endemic and EN category in the IUCN Red List
	Lyciasalamandra atifi	Local endemic and EN category in the IUCN Red List
	Lacerta pamphylica	Local endemic
	Testudo graeca	VU category in the IUCN Red List
	Neophron percnopterus	EN category in the IUCN Red List
	Streptopelia turtur	VU category in the IUCN Red List
	Myotis capaccinii	VU category in the IUCN Red List
	Rhinolophus mehelyi	VU category in the IUCN Red List
	Alburnus baliki	Endemic and EN category in the IUCN Red List
	Capoeta antalyensis	Regional Endemic and VU category in the IUCN Red List
	Oxynoemacheilus eregliensis	VU category in the IUCN Red List
	Pseudophoxinus fahrettini	Regional Endemic and EN category in the IUCN Red List

IX.7. Impact Assessment

The Antalya-Alanya Motorway project consist a range of both linear and area-based impacts on biodiversity. These impacts are primarily linked to the construction and operation of the motorway, including associated connecting roads and bridges. Additional biodiversity pressures are anticipated from supporting infrastructure such as quarries, construction sites, campsites, service roads, and temporary transportation routes.

The Study Area of the Project is located in a region where Modified Habitats, mainly agricultural land, make up 68% of the landscape. The remaining 32% consists of Natural Habitats, mostly maquis and coniferous forests.

Critical Habitats identified within the Study Area are triggered by different flora and fauna species as assessed in Section IX.5.6

Potential direct and indirect impacts have been evaluated for Modified Habitats, Natural Habitats, and Critical Habitats. The level of residual impact differs depending on the specific characteristics of each habitat type.

A full Critical Habitat Assessment and a Biodiversity Action Plan (BAP) have been developed as standalone documents.

The impact assessment for biodiversity follows the semi-quantitative method described in Chapter IV.

All proposed mitigation measures to be implemented on-site are detailed within the Biodiversity Management Plan (BMP), which serves as the guiding document for minimizing ecological impacts during project execution

The construction and operation of the Motorway Project will involve a wide range of activities that have the potential to affect the ecology. Impacts of project activities can be further divided into the target group of biological elements as terrestrial and aquatic. Important impacts of motorway construction and operation activities on the biological environment are mainly habitat fragmentation. Habitat fragmentation can be described as splitting natural habitats and ecosystems into smaller, more isolated patches. The process of fragmentation is connected to many different factors, of which the direct loss and isolation of natural habitat are the most important.

The ecological effects of transportation include disturbance in terms of noise and visual nuisance, and pollution, which reduce the suitability of adjacent areas for wildlife. The infrastructure itself contributes significantly towards habitat fragmentation by creating barriers to animal movement. This may result in the isolation and extinction of vulnerable species. The steady increase in the number of animal casualties associated with roads further indicates the fragmentation effect. Fauna mortality, in particular, has helped raise the public perception of the problem due to the inherent link to traffic safety.

During the planning, construction, or upgrading of transportation infrastructure, all possible efforts will be made to maintain or restore ecological structures and connect habitats and populations. Particular attention will be paid to rivers, streams, riparian forests, wooded corridors, networks of hedges and dikes, etc., which provide ecological corridors for growth, expansion of the range, and/or migration of wildlife populations and can often be the last refuge for many species in an intensively man-used landscape.

Best practice dictates that project planning and design aim to avoid ecological damage, especially to protect or sensitive habitats and/or species. The avoidance of fragmentation will be considered before resorting to mitigation measures. Following articles are general principles to consider against habitat fragmentation:

- The fragmentation of natural habitats by transportation infrastructure is a problem that can only be solved by accepting the issue at a policy level. Only an interdisciplinary approach involving planners, economists, engineers, ecologists, landscape architects, etc., can provide the necessary tools for successfully addressing fragmentation. Public involvement is also essential to ensure the success of the chosen solutions.
- Habitat connectivity is a vital property of landscapes and is especially important for sustaining animal movement across the landscape. The preservation of habitat connectivity will be a strategic goal in the environmental policy of the transport sector.
- Avoiding and mitigation will be applied from the start of the planning process.

The construction and operation of the Project will involve a wide range of activities that have the potential to affect the ecology. The relevant activities of the Project likely to give rise to impacts on receptors are summarized in Table IX.28, along with the possible pathway of the impacts.

Table IX.28 Overview of Potential Impacts of the Project on Biological Environment

Phase of the Project Activities	Activity	Potential Impact
Construction	Vegetation clearance	Damage or loss of habitats Loss of important plant species Direct incidental killing of fauna Loss of habitat for faunal species Increase in noise, visual and vibration which may cause disturbance or displacement of fauna Invasive species Loss of ecosystem services
	Campsites, storage areas and quarries	Damage or loss of habitat Increase in noise, visual and vibration which may cause disturbance or displacement of fauna
	Construction of culverts, bridges and viaducts	Damage or loss of habitat Increase in noise, and vibration and disturbance on fauna Disruption of ecological connectivity Loss of ecosystem services
	Presence of site preparation and construction vehicles	Increase in noise, visual and vibration which may cause disturbance or displacement of fauna Damage or loss of flora and /or fauna
Operation	Operational traffic	Increase in noise, visual and vibration which may cause disturbance or displacement of fauna Damage and/or loss of fauna Barrier effects Ecosystem Services

IX.7.1. Significant Receptors

The significant receptors, including protected areas, habitats and species, was assessed based on the significance criteria outlined in IFC Performance Standard 6 (PS 6). The sensitivities of these receptors were determined in order to calculate the overall impact on ecology.

IX.7.1.1. Internationally Recognized Areas and Nationally Protected Areas

The list of Internationally Recognized Areas in and around the impact area of the Project is provided in Table IX.10. IFC PS6 states that internationally and/or nationally recognized areas of high biodiversity value are likely to qualify as critical habitats, including KBAs, IBAs and IPAs. Therefore, all within and in the vicinity of the Project Area internationally recognized areas are highly sensitive.
There are 16 internationally Recognized areas found near the Project Area. There are no RAMSAR areas within or around the Project Area. The studies determined that a portion of Antalya Plains (KBA and IBA) is within the Project Area.

The portion of the Antalya Plains KBA/IBA intersecting the Project Area comprises exclusively modified habitats, which have been significantly altered by human activities and generally support lower biodiversity value compared to natural habitats. According to IFC Performance Standard 6, areas of modified habitat present low biodiversity sensitivity, and thus, the risk of significant adverse impacts on biodiversity values is reduced.

Given that the habitats within the project footprint do not include natural ecosystems or habitats critical for threatened or endemic species, the project's potential impacts on the biodiversity values of this protected area are expected to be minimal.

The Project also intersects with a portion of Belek SEPA. However this portion only consists of modified habitats such as agricultural lands and access roads, which makes about 44.5% of Belek SEPA's area. Belek SEPA is considered a nationally protected area due to it's natural beaches that *Caretta caretta* and *Chelonia mydas* species uses for nesting. It is not expected that the Project will have any impact on these areas. *Pyrus serikensis* which is also an important species for Belek SEPA is already considered and evaluated for this project, there are no individuals in the area that the Project and Belek SEPA intersects, however this species is present in other areas of the Projects area of impact.

The Project also intersect a small portion of Köprüçay Basin Natural Protected Area. This portion includes parts of the natural habitat and a viaduct is planned to be constructed above. The drilling activities are expected to have an impact of vibration for 5 meters and then reach extinction, and the distance for the nearest viaduct pier is 15 meters. Therefore the construction impacts on this protected area is to be minimal and general mitigations are expected to minimise the impact significance for this protected area.

IX.7.1.2. Habitats, Terrestrial Flora and Fauna Species

Biodiversity indicators and their sensitivities were assessed and categorized as high, medium, or low, considering the habitats and species present in the Project Area (Table IX.30).

In this assessment, species and habitat abundance within the Project Area have been classified into qualitative categories of "Low", "Moderate", and "High" to support the evaluation of potential impacts and the determination of magnitude. These categories reflect the expected relative abundance or density of individuals within the survey area, rather than precise population counts. Approximate numerical ranges for relative abundance, where "Low", "Moderate", "High" roughly correspond to the number of individuals or density observed in the impact area have been presented in Table IX.29. These are not exact counts however they are presented as a qualitative ratings.

Table IX.29 Relative Abundance Categories

Relative Abundance	Approximate Number of Individuals / Unit Area	Notes
Low	• Rarely observed or restricted species. • <15 individuals in the surveyed area or per hectare	• Rarely encountered, scattered, or restricted populations
Moderate	• Locally common but not dominant species • 20-100 individuals in the surveyed area or per hectare	• Locally common, • Detectable in surveys, • Not dominant but persistent
High	• Widespread or abundant species • >100 individuals per hectare	• Widespread and frequently observed • May dominate certain habitat patches

Table IX.30 Sensitivity of biodiversity receptors

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)	Sensitivity	Rationale
Habitats	S5 - Maquis, arborescent matorral and thermo-Mediterranean scrub	Moderate	Y	High	Natural habitats that qualify as Critical Habitat due to their high biodiversity value, ecological integrity, and presence of restricted-range and endemic species. These habitats provide essential ecosystem services, contribute to habitat connectivity, and are sensitive to fragmentation and disturbance.
	G1.1 - Riparian and gallery woodland, with dominant Alnus, Betula, Populus or Salix T3 - Coniferous forest T14 - Mediterranean and Macaronesian riparian forest S7.211 - Aegean *Sarcopoterium phrygana* S6 - Garrigue C2 - Surface running waters	Moderate	Y	Medium	Natural habitats of medium sensitivity that, although not qualifying as Critical Habitat under IFC PS6 thresholds, support native biodiversity, function as dispersal and feeding areas, and provide ecosystem services. These habitats are moderately resilient but remain vulnerable to degradation and fragmentation from construction activities.
	J1 - Buildings of cities, towns and villages V1 - Arable land and market gardens	Moderate	Y	Low	Modified habitats of low sensitivity, dominated by human activities. These areas provide little to no conservation value, are not important for threatened species, and do not qualify as natural or critical habitats under IFC PS6. Their biodiversity value is limited to common or disturbance-tolerant species.
Terrestrial Flora	*Pyrus serikensis*	Low	Y	High	Regional endemic and IUCN Endangered species with a highly restricted distribution. Its limited range and small population size increase vulnerability to habitat loss and fragmentation. Any impact on this species is considered highly significant given its conservation status and ecological importance.
	Eryngium kotschyi	Moderate	Y	Low	Endemic species with relatively wide ranges in Türkiye. Although they are locally common and resilient to disturbance, their endemic status warrants monitoring. Sensitivity is considered low because they do not meet thresholds for restricted range or Critical Habitat under IFC PS6.
	Phlomis leucophracta	Moderate	Y	Low	Endemic species with relatively wide ranges in Türkiye. Although they are locally common and resilient to disturbance, their endemic status warrants monitoring. Sensitivity is considered low because they do not meet thresholds for restricted range or

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)	Sensitivity	Rationale
					Critical Habitat under IFC PS6.
	Phlomis lycia	Moderate	Y	Low	Endemic species with relatively wide ranges in Türkiye. Although they are locally common and resilient to disturbance, their endemic status warrants monitoring. Sensitivity is considered low because they do not meet thresholds for restricted range or Critical Habitat under IFC PS6.
	Phlomis monocephala	Moderate	N	Low	Endemic species with relatively wide ranges in Türkiye. Although they are locally common and resilient to disturbance, their endemic status warrants monitoring. Sensitivity is considered low because they do not meet thresholds for restricted range or Critical Habitat under IFC PS6.
	Phlomis nissolii	Moderate	Y	Low	Endemic species with relatively wide ranges in Türkiye. Although they are locally common and resilient to disturbance, their endemic status warrants monitoring. Sensitivity is considered low because they do not meet thresholds for restricted range or Critical Habitat under IFC PS6.
	Sideritis congesta	Moderate	Y	Low	Endemic species with relatively wide ranges in Türkiye. Although they are locally common and resilient to disturbance, their endemic status warrants monitoring. Sensitivity is considered low because they do not meet thresholds for restricted range or Critical Habitat under IFC PS6.
	Barlia robertiana	Moderate	Y	Low	Orchid species listed in CITES Appendix II. Although not globally threatened, it is protected under international conventions due to collection pressures. Sensitivity is low as the species is not range-restricted, but it requires monitoring where present.
Amphibians and Reptiles	*Lyciasalamandra atifi*	Low	N	High	Endangered salamander with a highly restricted range and dependence on specific microhabitats. Although not observed in the project area, its conservation status and declining population makes it highly sensitive to any potential habitat disturbance.
	Testudo graeca	Moderate	Y	Medium	Vulnerable species widely distributed in Türkiye. Despite its IUCN status, it remains relatively abundant and adaptable to various habitats. Sensitivity is medium, reflecting its global conservation concern but regional commonness.
	Lacerta pamphylica	Low	N	High	Local endemic lizard with a narrow distribution, not observed in the project area and not globally threatened. Sensitivity is high due to its restricted range and dependence on specific habitats,

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)	Sensitivity	Rationale
					even if no direct project presence is confirmed.
	Anatololacerta ibrahimi	Low	N	Low	Regional endemic reptile with limited distribution but relatively stable populations. Sensitivity is low as they are not globally threatened and are generally tolerant of habitat variation.
	Ablepharus anatolicus	Low	N	Low	Regional endemic reptile with limited distribution but relatively stable populations. Sensitivity is low as they are not globally threatened and are generally tolerant of habitat variation.
	Blanus aporus	Low	N	Low	Regional endemic reptile with limited distribution but relatively stable populations. Sensitivity is low as they are not globally threatened and are generally tolerant of habitat variation.
	Other herpetofauna species	Moderate	Y	Low	Widespread amphibians and reptiles assessed as LC by IUCN with no special national protection status. These species are resilient to disturbance, resulting in low sensitivity.
Birds	*Neophron percnopterus*	Low	N	High	Endangered vulture species with a declining population globally. Not observed in the project area, but its conservation status and wide-ranging ecology mean that even potential disturbance is highly sensitive.
	Streptopelia turtur	Low	Y	Medium	Vulnerable migratory bird with declining populations due to hunting and habitat loss. Recorded in the project area, sensitivity is medium due to conservation status and use of agricultural/rural habitats
	Accipiter nisus	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Aquila chrysaetos	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Buteo buteo	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Buteo rufinus	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)	Sensitivity	Rationale
					stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Circaetus gallicus	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Circus aeruginosus	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Circus cyaneus	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Circus macrourus	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Ciconia ciconia	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Ciconia nigra	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Falco columbarius	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Falco peregrinus	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Falco subbuteo	Low	N	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)	Sensitivity	Rationale
					stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Falco tinnunculus	Low	Y	Low	Migratory species of least concern or near threatened status. Their use of the project area is transitory (migration flyway or stopover), not for breeding or nesting. Sensitivity is low, except where globally threatened species occur.
	Other bird species	Moderate	Y	Low	Species of LC or NT conservation status, without national protection, commonly occurring in anthropogenic-modified and natural habitats. Sensitivity is low.
Mammals	Mammal species except bats	Moderate	Y	Low	Common mammals assessed as LC or NT on the IUCN Red List. These species are resilient, widely distributed, and not of conservation concern. Sensitivity is low.
Mammals (Bats)	*Myotis capaccinii*	Low	N	Medium	Vulnerable bat species listed by IUCN. Although not recorded during surveys, they are cave-dwelling bats potentially vulnerable to disturbance, roost destruction, and changes in hydrology. Sensitivity is medium given global decline trends and specific roosting requirements.
	Rhinolophus mehelyi	Low	N	Medium	Vulnerable bat species listed by IUCN. Although not recorded during surveys, they are cave-dwelling bats potentially vulnerable to disturbance, roost destruction, and changes in hydrology. Sensitivity is medium given global decline trends and specific roosting requirements.
	Other bat species	Moderate	Y	Low	Other bat species present are widespread LC/NT taxa, generally tolerant of habitat modification, and without specific conservation concern. Their sensitivity is assessed as low
Fishes	*Anguilla anguilla*	Moderate	Y	High	Critically Endangered migratory fish with global population declines due to overfishing, barriers to migration, and habitat loss. Its occurrence in project waters confers high sensitivity
	Alburnus baliki	Moderate	Y	High	Endangered, range-restricted endemic species with small populations. Presence in project area increases sensitivity, as impacts may have significant consequences for its survival.
	Capoeta antalyensis	Moderate	N	High	Regional endemic and IUCN Vulnerable species. Although not observed in the project area, its restricted range and conservation status confer high sensitivity to potential impacts in its distribution range.

Biodiversity Receptor		Relative Abundance	Presence in Impact Area (Y/N)	Sensitivity	Rationale
	Pseudophoxinus fahrettini	Moderate	Y	High	Regional endemics, threatened (EN). Occurrence in project streams indicates high sensitivity due to restricted range, small populations, and dependence on freshwater integrity.
	Pseudophoxinus battalgilae	Moderate	Y	High	Regional endemics, threatened (EN). Occurrence in project streams indicates high sensitivity due to restricted range, small populations, and dependence on freshwater integrity.
	Cyprinus carpio	Moderate	Y	Medium	Vulnerable species, but widespread and abundant in natural and artificial habitats. Sensitivity is medium given global status but regional commonness.
	Capoeta caelestis	Moderate	Y	Medium	Endemic to southern Türkiye with a relatively wide distribution. Locally common and adaptable to different freshwater habitats. Not globally threatened. Sensitivity assessed as medium, reflecting its regional endemic status but absence of site-specific restriction.
	Cobitis battalgilae	Low	N	Medium	Endemic loach with a distribution extending beyond the project area. Although of conservation interest, it remains widespread in its range and is not considered globally threatened.
	Oxynoemacheilus eregliensis	Low	Y	Medium	Endemic to central and southern Türkiye and assessed as Vulnerable by the IUCN. Despite its status, it is not confined to the project area. Sensitivity assessed as medium, given conservation concern but wider distribution.
	Alburnus escherichii	Low	N	Medium	Freshwater endemic with a relatively broad distribution across Türkiye. Populations are not restricted to the project area, and the species is not globally threatened.
	Squalius anatolicus	Moderate	N	Medium	Endemic species with a wide distribution in Anatolia. It remains relatively common where suitable habitats occur.
	Squalius fellowesii	Moderate	Y	Medium	Endemic to southwestern Türkiye with populations present within the project area. The species is locally common and not of elevated global concern.
	Salmo ekmekciae	Low	N	Medium	Regional endemic trout with a limited but not project-specific distribution. While of ecological importance, it is not globally threatened.
	Other fish species	Moderate	Y	Low	Common LC or NT fishes without conservation concern or national protection. These species are tolerant of habitat disturbance.

Habitat Loss

The proposed motorway will require permanent land take and temporary occupation of land during construction. This will result in the direct loss of terrestrial and aquatic habitats along the alignment and in associated infrastructure areas.

Baseline surveys have identified 12 habitat types within the Project footprint, comprising both natural and modified habitats, with some areas meeting Critical Habitat criteria.

The total area of habitat loss has been quantified using a habitat hectare approach, which combines the area of each habitat with its condition score, distinctiveness, and strategic importance to provide a measure of biodiversity value. Predicted losses of natural habitats and critical habitat is given in Table IX.31 with their condition scores, distinctiveness, and strategic importance.

Table IX.31 Habitat Types, Covered Areas, Losses and Habitat Assessment Scores in the Project Area

Habitat Type	Total Study Area (ha)	Net Loss (ha)	Habitat Assessment Score		
			Distinctiveness	Condition	Strategic Importance
C2 Surface running waters	37	1.22	6	2	1
S5 Maquis, arborescent matorral and thermo-Mediterranean scrub	88	13.43	6	2	1
S5 Maquis, arborescent matorral and thermo-Mediterranean scrub *(Critical Habitat)*	259	58.76	6	2	1
S6 Garrigue	447	132.95	6	3	1
S7.211 Aegean *Sarcopoterium phrygana*	171	37.37	6	3	1
T3 Coniferous forest	1092	317.40	6	3	1
T1.4 Mediterranean and Macaronesian riparian forest	94	17.96	6	3	1

The losses include both permanent impacts (within the motorway carriageway footprint, embankments, and permanent facilities) and temporary losses during construction (e.g. site compounds, laydown areas), some of which will be reinstated post-construction.

The magnitude and significance of habitat losses vary depending on:

- Conservation value of the habitat
- Condition score of the habitat prior to impact
- Functional role in supporting key species
- Irreplaceability and potential for restoration

In addition to total habitat area lost, the motorway will create habitat fragmentation, isolating remaining habitat patches and potentially reducing ecological connectivity.

Terrestrial Flora

Türkiye has very rich plant diversity, with about 12,000 taxa, of which approximately 4,000 are endemic, meaning they grow only in Türkiye. Several factors contribute to Türkiye's plant richness,

including its diverse climate types, geological and topographical structure, and the presence of various rich habitats such as steppes, maquis, forests, rocks, wetlands, and beaches. Additionally, Türkiye is located at the intersection of the Euro-Siberian, Irano-Turanian, and Mediterranean phytogeographic regions. Beyond species richness, Türkiye's flora is also significant for containing the natural ancestors of many grains, legumes, and various fruits used as food products.

Through field surveys and literature reviews, the presence of 221 vascular plant taxa was identified within the project implementation area and its surroundings. Most of these species are widely distributed. Among them, seven species (*Eryngium kotschyi, Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis and Sideritis congesta*) are endemic. Considering their distribution patterns and the requirements for maintaining healthy populations, the Project Area does not possess critical habitat characteristics essential for these endemic taxa.

Amphibians

Based on observations and literature, it was determined that five amphibian species are distributed in the Project Area and the nearby region considered as the impact zone. Among these species, *Lyciasalamandra atifi* is endemic, while the remaining four species are widely distributed. According to the IUCN conservation status, one of the five species in the area is categorized as Endangered (EN), three are categorized as Least Concern (LC), and one species has not yet been evaluated (NE). *Lyciasalamandra atifi*, a land salamander endemic to Türkiye, is under threat due to factors such as climate change, collection, habitat destruction, the introduction of alien species, and urbanization.

Reptiles

Field studies conducted within the Project Area and its ecological impact boundaries, along with interviews with local people and literature data, have identified a total of 25 reptile species that could potentially inhabit the area. Among these, four species are endemic. The remaining 21 species are generally widely distributed and considered tolerant.

Regarding IUCN conservation status, it was determined that none of the reptile species in the area fall into a threatened category, except for *Testudo graeca*, which is categorized as Vulnerable (VU). The other species are classified as Least Concern (LC) or Not Evaluated (NE). *Testudo graeca*, despite being listed as VU, has a wide distribution across Türkiye, with healthy populations in the regions where it is found. The VU classification for this species is based on European populations.

Birds

The Project Area is located in a region with a high population density and various habitats, including aquatic ecosystems, agricultural areas, maquis, and forest areas. Based on field studies and literature, a total of 124 bird species have been identified in the Project Area and its immediate surroundings. None of the identified bird species are endemic, and all are widely distributed, cosmopolitan species. Most of these species are native to terrestrial habitats.

According to the IUCN conservation status, *Neophron percnopterus* (Egyptian vulture) is categorized as Endangered (EN), and *Streptopelia turtur* (European turtle dove) is categorized as Vulnerable (VU), *Circus macrourus (Pallid Harrier)* is categorized as Near Threatened (NT) and *Corvus cornix* (Hooded Crow) is Not Evaluated (NE). The remaining 120 species are classified as Least Concern (LC).

Mammals

It has been determined that 46 mammal species can be encountered in the immediate vicinity of the Project Area. Among these, two bat species (*Myotis capaccinii* and *Rhinolophus mehelyi*) are classified as “Vulnerable – VU “according to the IUCN Red List. Other mammal species identified in the Project Area and its surroundings are are classified as Least Concern (LC) and do not have critical sensitivity. None of the identified mammal species are endemic.

Fishes

It has been determined that 29 fish species are likely to be present in the streams along the motorway route. Among these, 11 species are endemic. Some of these endemic species are widely distributed. For those endemic species with a relatively narrow distribution, the Project Area and its impact zone do not exhibit critical habitat characteristics.

IX.7.2. Construction Phase Impacts on Ecology

The potential impacts on biodiversity are associated with the following impact factors:

- Vegetation and topsoil removal
- Habitat loss and habitat fragmentation
- Water pollution
- Noise and dust pollution
- Increase in vehicular traffic
- Light disturbance
- Invasive species

For the construction phase, the Project footprint was defined as a corridor along the Motorway Route, encompassing the motorway width (35.5 m), the minimum expropriation corridor (55 m), and extensions of up to 450 m at locations such as interchanges, large embankments and cut sections, and service areas. In addition to the main route, the impact assessment also considers wider project components including access roads, construction camps, material storage areas, borrow pits, quarries, and disposal sites, some of which are located outside the designated expropriation corridor. The effects identified for each section in relation to construction activities are summarized below.

Vegetation and Topsoil Removal

The Project's construction phase will require the removal of the majority of vegetation within the Project Area, and this is a direct adverse impact that is permanent and irreversible. The loss of vegetation will also cause fragmentation to the remaining areas of habitats in the Project Area. Construction activities including vegetation clearance and topsoil stripping, creation of campsites, storage areas and quarries, creation of culverts, bridges and viaducts, presence of site preparation, and construction vehicles have the potential to cause indirect adverse impact to surrounding habitats from runoff and dust.

On the other hand, cuttings and embankments change landscape topography and often induce large-scale changes in hydrology. Cuttings may increase soil erosion and drain aquifers, and Embankments may change the water regime producing either drier or wetter conditions. These changes will affect vegetation, e.g., in wetlands and riparian habitats.

Habitat Loss and Habitat Fragmentation

The assessment of habitat impact (removal of vegetation cover) is related to the structural value of the habitat for fauna and does not consider the species composition of the removed vegetation cover. Flora experts evaluated the species components of the vegetation cover and the threatening conditions.

The Project Area is predominantly comprised of maquis vegetation and agricultural lands, with occasional patches of degraded forest habitats. The construction of the motorway is not anticipated to significantly impact biodiversity in agricultural areas. However, some sections of maquis vegetation may experience alterations to their natural structure, and selecting natural forest areas for soil deposition could lead to negative effects on biodiversity. To mitigate these potential impacts, post-construction rehabilitation measures should be carried out to restore the natural characteristics of the affected habitats. Provided that appropriate conservation strategies are implemented, it is unlikely that the project will result in permanent habitat loss for plants.

One of the primary ecological concerns associated with motorway projects is habitat fragmentation. To maintain genetic diversity and ensure wildlife movement, it is crucial to facilitate connectivity between both sides of the road. Ecological overpasses should be strategically placed to support animal movement. However, due to the region's topography and the presence of rivers, the motorway will incorporate 16 viaducts, 22 bridges, and at-grade crossings, which are expected to serve this purpose. Additionally, because the motorway runs parallel to the Mediterranean coast at a low elevation (10-160 m), no north-south migrating species have been identified in the area. The southern side of the motorway also lacks continuous habitats, reducing the likelihood of significant habitat fragmentation. Furthermore, since the southern side of the Motorway does not have contiguous habitats, the Project is expected to cause minimal habitat fragmentation. 305 culverts will be constructed along the motorway to reduce the residual effects of habitat fragmentation, the relevant maps are presented in Annex 11C of this ESIA report.

Water Pollution

Violation of the vegetation cover and the natural environment of the region will cause degradation or destruction of habitats in these regions. The construction of motorways will affect rivers damaged by excavation and blasting, the construction of artificial structures, the smoothing of beds of stream flows, and the activities of flood areas. Construction and excavation work in the coastal regions of waterways affect aquatic organisms, water-supported habitats, and fauna species. Contamination of pollution during activities and increasing water blurring will inevitably occur. If the mitigation measures are not taken, this contamination can result in reduction or destruction settlement of the basin gradual and natural biosynthetic reservoirs.

Noise and Dust Pollution

The effects of the construction activities will include dust, noise, and vibration. These effects may impact indigenous mammalian species, but none of these effects will have a lasting impact on species. After the construction activity is over, it is expected that the composition of the fauna species will return to its original state in time.

Increase in Vehicular Traffic

During the construction phase, an increase in vehicular traffic is anticipated within the construction site and across various project facilities. As a result, there is a potential for direct impacts, including accidental collisions with wildlife. The Project will primarily utilize existing roads for transportation. However, the increased traffic volume may also lead to indirect negative impacts, such as habitat degradation, which could adversely affect wildlife populations that are dependent on specific habitat conditions.

In general, traffic can significantly influence wildlife behavior and distribution patterns, potentially leading to displacement or avoidance of affected areas.

Introduction and Spreading of Invasive Species

The removal of natural vegetation cover and soil disturbance during the construction phase may facilitate the spread of invasive alien (non-native) species. These species can be inadvertently introduced via construction vehicles, trucks, and heavy machinery operating within the project area.

Invasive alien species often thrive in disturbed ecosystems and, once established, may alter habitat functionality and species composition. This includes potential adverse effects on priority biodiversity species.

Applying a precautionary approach, a 100-meter buffer around all Project facilities has been considered for assessing the risk and potential impact of invasive species introduction and spread.

IX.7.2.1. Internationally Recognized Areas

The magnitude of the construction impacts in internationally recognized areas intersecting with the Project Area is evaluated as significant for more than 3% of the intersection area. The areas smaller than 3% of the intersection areas are considered negligible. Within the scope of the Project, only Antalya Plains and Belek SEPA, and Köprüçay Basin intersects with the Motorway. Total intersection areas have been determined and is given inTable IX.8 and Table IX.9.

The assessment will include the habitat loss calculations due to construction activities. Given the distance, predicting any adverse indirect impacts from changes in air quality, the introduction of invasive species or disturbances during the construction phase is challenging, making a comprehensive assessment in this regard difficult to provide.

IX.7.2.2. Impacts on Natural and Modified Habitats

Most significant impact due to the construction phase of the Project is the habitat fragmentation. The loss of vegetation will also cause fragmentation to the remaining areas of habitats in the vicinity of the Project Area. For this reason, the quality of the habitat and the biodiversity of the habitat will be adversely affected.

The Project's construction phase will require the removal of the majority of vegetation, and it is a direct adverse impact that is permanent and irreversible.

The magnitude of construction impacts on terrestrial habitat types evaluated and given inTable IX.32.

Table IX.32 The magnitude of Construction Impacts on Terrestrial Habitats

Habitat	Potential Impact	Magnitude of Impacts
S5 - Maquis, Arboreal Matorral, and Thermo-Mediterranean Scrub	Habitat loss and habitat fragmentation Vegetation and topsoil removal Noise and dust pollution	Medium (Adverse)
G1.1 - Riparian and Gallery Forests Dominated by Alnus, Betula, Populus, or Salix Genera		
T14 - Mediterranean and Macaronesian Riparian Forest		
S7.211 - Aegean Sarcopoterium phrygana		
S6 - Garrigue		
T3 - Coniferous Forest		
J1 - Urban, Town, and Village Buildings		
V1 - Arable Land and Market Gardens		
C2 - Surface Flowing Waters	Habitat loss and habitat fragmentation Water pollution	

Construction activities including vegetation clearance and topsoil stripping, creation of campsites, storage areas and quarries, construction of culverts, bridges, and viaducts, and presence of site preparation and construction vehicles have the potential to cause indirect adverse impact to surround habitats from runoff and dust. Runoff can introduce silt, nutrients, chemical contaminants, and non-native species without mitigation. In addition, construction activities, the importation of fill, and the movement of people and vehicles can introduce invasive species that may impact the remaining adjacent habitats before implementing mitigation measures.

In order to accurately quantify habitat loss resulting from the direct impacts of construction activities, certain structures and areas were excluded from the final loss caculations. These include infrastructure such as viaducts, and tunnels that do not cause habitat fragmentation, as well as temporarily affected areas such as campsites that are scheduled for rehabilitation.. Each habitat has been aveluated individually for net loss/gain and necessary details are given in Table IX.33.

Table IX.33. Net Loss of Natural Habitats Within Study Area

Habitat	Total Study Area (ha)	Net Loss (ha)	% of Loss by Total Study Area
C2 Surface running waters	37	1.22	3.3
S5 Maquis, arborescent matorral and thermo-Mediterranean scrub	88	13.43	15.3
S5 Maquis, arborescent matorral and thermo-Mediterranean scrub *(Critical Habitat)*	259	58.76	22.7
S6 Garrigue	447	132.95	29.7
S7.211 Aegean *Sarcopoterium phrygana*	171	37.37	21.9
T3 Coniferous forest	1,092	317.40	29.1
T1.4 Mediterranean and Macaronesian riparian forest	94	17.96	19.1
Total	**2,188**	**579.09**	**26.5**

IX.7.2.3. Impacts on Flora and Fauna

Terrestrial Flora

Baseline surveys identified seven endemic plant species within the Project Area: *Eryngium kotschyi, Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis,* and *Sideritis congesta.* Among these, *Pyrus serikensis* is of particular importance as a regional endemic with a restricted distribution and conservation concern. Field observations recorded approximately 20 individuals of *Pyrus serikensis* in localized patches within the maquis habitat, with possibility of more. Loss of these individuals, combined with removal of associated soil seed banks, would represent a notable proportion of the local population, leading to a Medium (Adverse) impact magnitude prior to mitigation.

The other six endemic species were found to be widespread across multiple habitat types, often occurring with low individual densities but broad distribution within the study area. Given their wider ecological tolerance, given that these species relative abundance was assessed as moderate (which quantifies as 20-100 individuals in the area), the impact of habitat clearance and construction disturbance is expected to result in localized losses but not threaten population viability at the regional level,.. Therefore, construction impacts on these species are classified as Low–Medium (Adverse) prior to mitigation. The magnitude of construction impacts on flora species of conservation importance within the project scope is provided in Table IX.34.

Table IX.34. The magnitude of Construction Impacts on Plant Species

Species	Potential Impact	Magnitude
Pyrus serikensis	Vegetation and topsoil removal Habitat loss and habitat fragmentation Noise and dust pollution	Medium (Adverse)
Eryngium kotschyi		Low-Medium (Adverse)
Phlomis leucophracta		
Phlomis lycia		
Phlomis monocephala		
Phlomis nissolii		
Sideritis congesta		

Amphibians and Reptiles

Baseline herpetofauna surveys identified one amphibian species of conservation concern, *Lyciasalamandra atifi*, and several reptile species within and/or around the Project Area.

Lyciasalamandra atifi was observed outside of Project Area with a total of 4 individuals recorded. Given its localized distribution and habitat specificity, the loss of vegetation and topsoil removal will result in localized habitat loss but not a significant reduction in the species' wider population, leading to a Low (Adverse) impact rating.

Testudo graeca populations were recorded more frequently, across the Project Area. No individual numbers were recorded for this species as this species is quite widespread and has a stable population in Türkiye. Consequently, the magnitude of impacts on this species is considered Low (Adverse) prior to mitigation.

The remaining reptile species present in the area were observed at moderate densities (20-100 individuals) across multiple habitat types. Altough vegetation clearance will cause direct mortality and local population reductions, their wider distribution and higher reproductive capacity indicate that regional populations are unlikely to be significantly affected. Therefore, these species are assessed as Low (Adverse) prior to mitigation.

The magnitude of construction impacts on amphibian and reptiles species of conservation importance within the Project scope is provided in Table IX.35.

Table IX.35. The magnitude of Construction Impacts on Amphibian and Reptiles

Species	Potential Impact	Magnitude
Lyciasalamandra atifi	Habitat loss and habitat fragmentation	Low (Adverse)
Testudo graeca	Vegetation and topsoil removal Habitat loss and habitat fragmentation	
Lacerta pamphylica		
Anatololacerta ibrahimi		
Ablepharus anatolicus		
Blanus aporus		

Birds

The forest, riparian habitats, and wet meadows in natural habitats on the route are susceptible for birds as feeding, breeding, and sheltering areas. For this reason, the water regime of riparian and wet meadow habitats outside of the Motorway route, which motorway construction can affect, mitigations will be taken. Otherwise, if the water regime of these sensitive habitats is diminishing and/or discontinued, the feeding and sheltering habitats for birds will disappear that are directly and/or indirectly dependent on the aquatic environment. The motorway corridor where the Project will be implemented does not exhibit specialized habitat characteristics that uniquely support these species for breeding, feeding, or wintering. Due to their ability to fly, bird species are not expected to be destroyed, therefore no individual losses are expected, as they can relocate to alternative habitats. Therefore, significant adverse effects on birds species due to the Project activities are not expected.

The magnitude of construction impacts on bird species of conservation importance within the Project scope is provided in Table IX.36

Table IX.36. The magnitude of Construction Impacts on Birds

Species	Potential Impact	Magnitude
Neophron percnopterus	Vegetation and topsoil removal Habitat loss and habitat fragmentation	Low (Adverse)

Circus macrourus		
Ciconia ciconia		
Ciconia nigra		
Falco columbarius		
Falco peregrinus		
Falco subbuteo		

Species	Potential Impact	Magnitude
Falco tinnunculus		

Mammals

The construction phase of the Project will eliminate most of the vegetation within the Project Area, including habitats that support mammal species. The removal of vegetation is also expected to cause fragmentation of the remaining habitats around the Project Area. Due to disturbances from construction noise and activities, large mammal species are expected to relocate to suitable habitats during the construction activities.

Baseline surveys documented several mammal species within and around the Project Area, with bats (*Myotis cappaccinii, Rhinolophus mehelyi*) representing the most conservation-sensitive group, identified from literature. Non-volant mammals such as *Vulpes vulpes*, *Lepus europaeus*, and *Erinaceus concolor* were recorded opportunistically, while larger mammals such as *Canis aureus* were also noted by tracks and local reports, confirming their occasional presence but indicating they are not resident in high numbers. All of the mammal species around the Project Area are considered to have 20-100 individuals, however only a few individuals were recorded during surveys. Non-volant mammals are generally wide-ranging and adaptable to disturbance. Construction-phase impacts on these species will largely be limited to localized habitat displacement and temporary disturbance, with no expected population-level consequences due to them leaving the construction site because of the disturbance, therefore the planned project is not expected to have a direct impact on them.

The most common mammal group in and around the Project Area is bats, most of them being identified from literature studies. Bats may be observed flying during feeding or migration periods. Bat species generally use caves, tree holes, or buildings for nesting. Quarries located in the Project Area are examples of these nesting areas and there is a possibility that the species may nest there. As a result, the magnitude of construction impacts on mammal species of conservation importance within the Project scope is provided inTable IX.37.

Table IX.37. The magnitude of Construction Impacts on Mammals

Species	Potential Impact	Magnitude
Myotis capaccinii	Vegetation and Topsoil Removal Habitat Loss and Habitat Fragmentation	Medium (Adverse)
Rhinolophus mehelyi		

Fishes

When the literature data and field studies were evaluated according to the IUCN conservation status, it was found that five species are under threat. It is well known that anthropogenic effects can have numerous negative impacts on fish species, the most significant being changes in water quality and habitat degradation. During field surveys, occasional individuals were recorded, indicating migratory use rather than resident populations. Most native cyprinids are relatively tolerant to disturbance but remain vulnerable to water pollution. Endemic species are more sensitive to localized habitat changes however considering the Project does not have significant effects on aquatic habitats, impacts on all fish species and populations are expected to to be Low (Adverse).

The Project is not expected to cause water quality deterioration. No negative effects are anticipated if the recommended measures to prevent habitat degradation during the construction of bridges and viaducts are implemented.

In conclusion, it has been observed that the activities to be carried out as part of the Project will not impact the distribution and population density of fish species. The magnitude of construction impacts on fish species within the Project scope is provided in Table IX.38.

IX.7.3. Operation Phase Impacts on Ecology

The potential impacts on biodiversity are associated with the following impact factors:

- Presence of new buildings and infrastructures
- Disturbance and pollution
- Motorway traffic
- Invasive species

For the operational phase, the project footprint was defined to include the Project route with a 20-meter buffer on each side. This footprint also encompasses permanent infrastructure such as stations, switchyards, bridges, overpasses, underpasses, and viaducts.

Temporary facilities, including construction camps, concrete and precast plants, and storage areas, borrow sites, quarries, and the basalt quarry, were excluded from the operational footprint. These facilities are planned to be fully rehabilitated following the completion of the construction phase.

Indirect impacts during the operational phase were conservatively assessed within buffer zones extending 100 to 300 meters from the edges of the defined project footprint and temporary facilities.

Since the construction period effects are long-term effects, the duration of the operation period is also included. Therefore, the magnitude of the construction phase impacts will also be valid for the operating period for some species.

There will be several potential impacts for ecological components along the Motorway route during the operation phase. These impacts include operational traffic and noise and visual disturbance, damage and/or loss of fauna, barrier effect, changes in air quality (pollution), and surface and groundwater quality (pollution). Relating surface and groundwater quality and air quality are described in Chapter 8 ("Water Resources") and Chapter 10 ("Air Quality and Climate Change"), respectively.

It will be noted that the baseline may have shifted considerably from conditions pre-construction after construction. As such, impacts on species have been predicted, adopting a precautionary approach that assumes species are still present along the Motorway.

Presence of new buildings and infrastructures

The areas affected by this impact factor will be limited to the Project footprints, including permanent facilities. Temporary facilitates such as quarries, borrow sites, storage area for excess excavated material, blasting areas are planned to be reclaimed after the construction phase. However, the rehabilitation of these areas must be carefully monitored to make sure the target is met.

Barrier effects: The barrier effect of roads is probably their most significant negative ecological impact. The dispersal ability of individual organisms is one of the critical factors in species survival. The ability to move around a landscape in search of food, shelter, or mate is negatively impacted by barriers that cause habitat isolation. Impacts on individuals affect population dynamics and often threaten species' survival. The only way to avoid the barrier effect is to make infrastructure more permeable to wildlife through fauna passages, adapt engineering works, or manage traffic flows. Carefully selecting the road route through the landscape can minimize the barrier problem.

Due to the habitat fragmentation effect, the barrier effect is the most significant adverse effect for small and large mammal species. Impacts on individuals affect population dynamics and often threaten species' survival. The barrier affects can investigate in two points as follow:

- *Physical barrier:* Transport infrastructure becomes a complete barrier for larger mammals only if fenced or if traffic intensity is high. For smaller animals, especially invertebrates, the road surface and verge impose a more substantial barrier because the substrate is barren or the disturbance is too great.
- *Behavioral barrier:* Many larger wildlife species avoid areas near roads related to the degree of human disturbance (traffic density, secondary development). Wild reindeer in Norway, for example, under-utilize their grazing resources within 5 km of roads. Other animals, such as small mammals and some forest birds exhibit behavioral avoidance patterns when crossing large open spaces.

Table IX.39. The relationship between road traffic density and the barrier effect on mammals

Traffic density	Permeability
Road with traffic below 1000 vehicles/day	Permeable to most wildlife species
Roads with 1000 to 4000 vehicles/day	Permeable to some species but avoided by more sensitive species.

Roads with 4000 to 10000 vehicles/day	Strong barriers, noise, and movement will repel many individuals. Many trying to cross the road become road casualties.
Motorways with traffic levels above 10000 vehicles/day	Impermeable to most species.

Within the scope of motorway projects, traffic flow can be impenetrable for mammal species. However, recommended culverts will be used as animal passes, preventing mortality due to the traffic flow. For the Antalya-Alanya Motorway Project, it's been assessed as no medium to large mammal species uses the Project area as a passage, however considering the Annual Average Daily Traffic is expected to be approximately 25000 vehicles/day and the impermeability in Table IX.39 additional measures such as culverts, underpasses, viaducts and/or bridges will be implemented to ensure safe passages and to reduce barrier effects.

If mitigation measures are not taken for noise control, noise impacts would be disturbed a large area of terrestrial habitats. While smaller species of mammals may not be significantly affected by disturbance, larger and more reclusive species such as wild cats are likely to avoid the vicinity of the motorway.

Disturbance and pollution

Road development and operation alter the ecological characteristics of adjacent habitats, which may induce changes in the way they are used by wildlife. Many of these changes can affect habitat quality at a significant distance from the infrastructure development.

The following are the main types of disturbance associated with transport infrastructure:

- Chemical pollution:
  - A wide range of pollutants are derived from road traffic and the road surface.
  - Motor exhausts give rise to, for example, carbon monoxide, nitrogen oxides, sulphur dioxide, hydrocarbons, including polycyclic aromatic hydrocarbons (PAH), dioxins, and particles.
  - Vehicles are sources of heavy metals such as lead, zinc, copper, and cadmium. Sodium and chloride pollution comes from de-icing salt.
  - The chemicals pollute surface and groundwater, soil and vegetation along roads.
  - Compounds containing nitrogen and sulphur contribute to acidification and eutrophication.
  - Pollutants can disrupt biological functions at multiple levels of organization, ranging from cellular processes to individual organisms and entire populations.

- Noise and vibration:
  - The disturbance from noise is mainly influenced by traffic, traffic intensity, road surface properties, topography, rail type, and the structure and type of the adjacent vegetation.
  - Geological and soil characteristics influence the magnitude and spread of vibrations.
  - Some species avoid noise-disturbed areas. For example, in the Netherlands, bird densities declined where the traffic noise exceeded 50 dBA, whereas woodland birds were sensitive to noise levels as low as 40 dBA.

- Some species maintain moderate population densities in disturbed habitats; however, their reproductive success is significantly reduced under such conditions.

- Lighting and visual disturbances:
  - Artificial lighting, such as overhead streetlights, can affect growth regulation in plants, disturb breeding and foraging behaviour in birds or influence the behaviour of nocturnal amphibians.
  - "Artificial lighting, particularly from mercury vapor lamps, can attract large numbers of insects, which may lead to increased local bat activity along roads and consequently elevate the risk of bat mortality due to vehicle collisions..

Motorway Traffic

Fauna casualties: Mortality is probably the best-known impact of traffic on wildlife. Millions of individuals of a wide range of wildlife species are killed on roads mostly. Large numbers of fauna casualties may not necessarily imply a threat to populations but indicate that the species involved are locally abundant and widespread.

Traffic mortality will be considered responsible for just a small proportion (1-4%) of the total mortality of common species (rodents, rabbits, foxes, sparrows, blackbirds, etc.). However, unless mitigation measures are taken, traffic can cause mortality and significantly affect local population survival for more sensitive species.

Invasive Species

Motorway corridors often undergo habitat changes, as their verges typically differ in structure and composition from the surrounding landscape, while remaining relatively uniform along the motorway. These altered habitats can be exploited by generalist species and opportunistic individuals, which may use the verges as movement corridors or temporary shelters.

Such conditions can also facilitate the establishment and spread of invasive species, further altering local biodiversity dynamics and potentially impacting native species and ecosystem functionality.

Terrestrial Flora

During the operation phase, the primary impacts on flora are expected to stem from barrier effects, pollution, and the facilitation of invasive species spread along disturbed corridors.These impacts are more subtle than those during construction but can lead to long-term population decline in sensitive or narrowly distributed species.

Among the seven recorded endemics, *Pyrus serikensis* is of particular concern due to its very restricted distribution. Baseline surveys confirmed only small and scattered populations. Making it more vulnerable than other species regarding barrier effects and soil chemistry alteration.

Other endemics occur more widely, but nonetheless sensitive to pollution (dust, exhaust emissions), and to competition from invasive plants that may occur by road edges. These species are more tolerant but still face risks from localized impacts.

Overall while operational impacts may not cause immediate losses, they can gradually reduce population viability over time, especially for species with restricted ranges such as *Pyrus serikensis.* Considering the endemic species being widespread in the region no significant population loss is expected to occur during the operation phase. With the sensitivity of *Pyrus serikensis* in mind, the magnitude of operation impacts on terrestrial flora species within the Project scope is provided in Table IX.40.

Table IX.40. The magnitude of Operational Impacts on Plant Species

Species	Potential Impact	Magnitude
Pyrus serikensis	Noise and dust pollution Alteration of soil chemistry	Medium (Adverse)
Eryngium kotschyi		Low (Adverse)
Phlomis leucophracta		
Phlomis lycia		
Phlomis monocephala		
Phlomis nissolii		
Sideritis congesta		

Amphibians and Reptiles

During the operational phase, amphibians and reptiles are mainly threatened by habitat fragmentation and barrier effects, which hinder seasonal movements between foraging, breeding, and overwintering habitats. Amphibians are particularly vulnerable due to their dependence on humid microhabitats and relatively low dispersal capacity.

Species such as *Lyciasalamandra atifi*, already restricted in range, may suffer localized population declines due to vehicle collisions during migration or post-rain activity. However considering that this species is not present in the Project Area, it is not expected that this impact will be significant.

The magnitude of operation impacts on amphibian and reptile species within the Project scope is provided in Table IX.41.

Table IX.41. The magnitude of Operational Impacts on Amphibian and Reptiles

Species	Potential Impact	Magnitude
Lyciasalamandra atifi	Mortality due to vehicle collisions	Low (Adverse)
Testudo graeca	Mortality due to vehicle collisions	
Lacerta pamphylica		
Anatololacerta ibrahimi		
Ablepharus anatolicus		
Blanus aporus		

Birds

During the operational phase of the motorway, birds may be impacted by continuous noise and light disturbance, which can interfere with breeding behavior, and territory establishment, particularly for songbirds and nocturnal species. The presence of fast-moving vehicles increases the risk of collisions, especially for low-flying or ground-nesting species. Additionally, changes in vegetation structure along road verges and increased human activity can create unsuitable conditions for sensitive or specialist bird species.

Baseline surveys indicate that most species in the Project Area are wide-ranging species, migratory birds, or generalist woodland species, capable of relocating to alternative habitats in the vicinity. Although some edge effects may occur along road verges, the overall availability of suitable habitats outsite the corridor is sufficient to maintain populations, limiting long-term population-level impacts.

As a result, all operational phase impacts are assessed as Low (Adverse). The magnitude of operation impacts on bird species within the Project scope is provided in Table IX.42.

Table IX.42. The magnitude of Operational Impacts on Birds

Species	Potential Impact	Magnitude
Neophron percnopterus	Mortality due to vehicle collisions Disturbance from light/noise	Low (Adverse)
Streptopelia turtur		
Accipiter nisus		
Aquila chrysaetos

Buteo rufinus		
Circaetus gallicus		
Circus aeruginosus		
Circus cyaneus		
Circus macrourus		
Ciconia ciconia		
Ciconia nigra		
Falco columbarius		
Falco peregrinus		
Falco subbuteo		
Falco tinnunculus		

Mammals

During the operational phase of the project, mammals may experience impacts due to habitat fragmentation, increased mortality risk from vehicle collisions, and distruption of established movement corridors and commuting routes.

Survey results show that no big or medium size mammals use the motorway corridor as a regular movement corridor, so impacts on these species are limited to minor disturance in adjacent habitats. No permanent population losses are expected for wide-ranging species. Light pollution due to artifical lighting along the motorway can alter foraging behavior, deter species from using traditional paths, or

attract them to hazardous areas with high traffic activity, especially for nocturnal species and bats. Noise pollution and the creation of edge habitats may reduce habitat quality for both bats and terrestrial mammals, potentially leading to long-term population declines and reduces genetic connectivity. However these impacts are not expected to be significant for terrestrial mammals. The magnitude of operation impacts on mammal species within the Project scope is provided in Table IX.43.

Table IX.43. The magnitude of Operational Impacts on Mammals

Species	Potential Impact	Magnitude
Myotis capaccinii	Mortality due to vehicle collisions Light pollution Noise pollution	Medium (Adverse)
Rhinolophus mehelyi		

Fishes

Fish populations may be affected by alterations in water quality and hydrology caused by runoff containing pollutants such as oil, heavy metals, and road salts entering nearby water bodies, potentially leading to habitat degradation, reduced oxygen levels, and increased stress or even mortality. Changes to stream flow patterns from culverts or drainage structures can distrupt spawning grounds and migration routes, particularly for species that depend on specific flow conditions for reproduction. Baseline surveys indicate that most fish species in the Project Area are relatively widespread or tolerant of moderate disturbance. Provided that bridge and viaduct construction ensures fish passage, impacts on fish populations are expected to remain Low (Adverse).

In conclusion, it has been observed that the activities to be carried out as part of the Project will not impact the distribution and population density of fish species. The magnitude of operation impacts on fish species within the Project scope is provided in Table IX.44.

IX.8. Mitigation Measures

The following section details the mitigation measures are detailed the following sections to avoid, reduce and offset potential impacts for ecology and biodiversity from the Project. These measures are described under two headings: the construction and operation phases.

IX.8.1. Construction Phase

The general measures to be taken to the effects on the biologic environment from the Project activities during the construction phase are given below.

General Mitigations

General mitigation measures will be implemented during the construction phase to protect ecological receptors as follow:

- Study areas will be clearly defined before vegetation clearance, where construction activities will occur.
- Access roads will be clearly defined before the onset of construction activities not to harm flora elements outside the construction sites.
- Project construction sites and access roads will be separated from other areas with appropriate signboards, signs, and fences. Therefore, staff and vehicle access to the area will be limited to the construction site.
- Vegetation clearance will take place gradually, so fauna elements will be allowed to leave construction sites align with the construction work programme
- During vegetation clearance, equipment will be selected not to harm plant roots
- The intrusion of any invasive species into the Project Area and its surroundings will be prevented. For this purpose, vehicles used for vegetation clearance and/or plant transfer will be checked beforehand.
- Construction waste generated due to project activities will be stored at designated storage areas, and then disposed of solid waste will not be allowed to be left in natural habitats.
- The construction phase will be carried out with a biodiversity specialist or adequately trained personnel to take mitigation measures and interfere with some impacts from construction activities taken where necessary.
- Measures to reduce noise are provided in Chapter 11 (“Noise and Vibration”) for details.
- Measures to reduce dust and air pollution are provided in Chapter 10, (“Air Quality and Climate Change”).
- Project workers will not be allowed to bring any live animals or plants into the construction site to avoid the risk of pest/invasive species establishing in the Project Area.
- No ecological bridges are recommended as there’s no suitable wildlife passage that occurs within the fragmented habitats. Culverts, viaducts, and tunnels are recommended at suitable locations. Details are given in Biodiversity Management Plan in greater detail.
- Pre-blasting surveys will be carried out by the Biodiversity Specialist.

Terrestrial Habitats and Flora

The majority of the Project Area is composed of maquis vegetation and agricultural lands, with some patches of degraded forest habitats. The construction of the motorway is not expected to have a substantial impact on biodiversity within agricultural areas. However, certain sections of maquis vegetation may experience a loss of natural structure, and the selection of natural forest areas for soil deposition may lead to negative biodiversity consequences. To mitigate these potential impacts, post-construction rehabilitation efforts shall be undertaken to restore the natural characteristics of the affected habitats. With appropriate conservation strategies in place, it is unlikely that the project will result in permanent habitat destruction for vascular plants.

While the project site and surrounding areas are not considered critical for plant biodiversity in Türkiye, minimizing human-induced disturbances and adhering to conservation guidelines remain essential for preserving local biodiversity and ensuring its sustainability.

To ensure the conservation of endemic plant species (*Eryngium kotschyi, Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis, Sideritis congesta*) it is crucial to monitor this species, assess potential threats, and implement habitat restoration measures, including planting them in suitable environments. This strategy aims not only to prevent population decline but also to enhance population density in the region.

Seeds collected from endemic species in the region will initially be delivered to a seed bank. During the biorestoration phase, the excess collected seeds will be planted in suitable vegetation areas for in-situ conservation purposes.

Terrestrial Fauna

The following mitigation measures are to minimize the potential impacts of the Project on terrestrial fauna:

- Habitat loss, noise, dust, and vehicle-human traffic will be managed by implementing construction activities gradually to provide birds with the necessary time and energy to leave the area.
- Forest and maquis habitats are important breeding, nesting, and feeding areas for large mammals, forest bird species, and turtles. Therefore, it has been deemed appropriate and beneficial to construct culverts in the forested sections of the motorway where the topography is suitable for the passage of large mammals and other species.
- Nesting birds in the Project Area and its surroundings will be monitored during the construction and operational phases, particularly in spring and autumn. After the construction period, checks will be made to see if nesting occurs again in previously occupied areas.
- To prevent the entry of fauna into construction areas, the sites will be fenced. Additionally, traffic will be restricted within the Project Area, except on pre-designed routes, to prevent harm to animals.

Amphibians: *Lyciasalamandra atifi*, an endemic terrestrial salamander, is found in isolated populations along the Taurus Mountains between Alanya and Serik, at elevations ranging from 190 to 1,400 meters. Although field surveys did not detect this species within the Project Area, potentially suitable habitats exist, and as a precautionary measure, *Lyciasalamandra atifi* has been included in the species list. Given that the project corridor lies below its typical elevation range (10-160 meters), it is not considered part of the species' natural distribution. However, due to its endemic status, if the species is detected within the Project Area, a qualified biologist will conduct surveys prior to any surface stripping, excavation, or filling activities. Any individuals found will be safely collected and relocated to appropriate nearby habitats.

Reptiles: The region does not provide critical habitats for breeding, feeding, or sheltering for reptile species. Reptiles are likely to use the area primarily for daily foraging activities, and some species may hibernate in suitable locations. Due to their tendency to avoid human activity, reptiles are expected to move away from construction sites during motorway construction. Additionally, similar habitats are available nearby, ensuring the survival of these species. However, hibernating species that burrow underground could be impacted by surface stripping, excavation, and filling operations. To mitigate this risk, such activities will be avoided during the hibernation period (December–February). If construction is necessary during winter, a qualified biologist or expert will monitor the site and relocate any hibernating individuals to safe areas outside the construction zone.

Birds: The motorway corridor encompasses a variety of habitat types, supporting 124 bird species, the majority of which are migratory. No critical breeding, feeding, or wintering habitats for birds have been identified within the corridor. Most species primarily use the area for foraging. While the project site does not provide specialized habitats for birds, some species with high ecological tolerance may still nest in the area. With the implementation of the recommended mitigation measures, the project is not expected to have a negative impact on bird populations.

Mammals: The predominant mammalian species in the Project Area are rodents, which include both subterranean and semi-subterranean species, such as blind moles and field mice. These rodents are highly adaptable ecologically and have high reproductive rates, resulting in large population densities. However, their distribution is currently restricted by agricultural practices like soil tilling and pesticide application. While construction activities may cause temporary displacement of some individuals, the availability of comparable habitats nearby indicates that the impact will be minimal. Furthermore, given that rodent species naturally re-establish their underground burrows, it is anticipated that their populations will recover following the completion of the project.

Bats: The Project Area hosts the threatened bat species *Myotis capaccinii* and *Rhinolophus mehelyi*. As the rocky sections designated for quarrying offer suitable roosting habitats, it is crucial to conduct pre-construction monitoring to assess the presence of these species. If individuals are detected, appropriate measures will be taken to ensure their safe relocation prior to the commencement of stone crushing operations.

Aquatic Environment

During the construction of transition structures on aquatic systems, the bridge piers will be designed to not come into the stream beds. In this case, there will be no direct interference with aquatic habitats. However, there may be interventions on both the riparian areas and beds of aquatic systems during these works for various reasons. To create the necessary sensitivity against such situations that may occur, it is recommended to take the measures given below and related to the aquatic ecosystem.

The following mitigation measures are to minimize the potential impacts of the Project on aquatic habitats and species:

- Excavation materials will not be dumped onto a riverbed.
- Mixing any chemical substances used in the construction area, in the waterbed, and/or aquatic ecosystems will be prevented.
- Viaduct or bridge construction activities will be conducted in months other than April-May, which is the breeding period, as turbidity can have lethal effects on fish eggs. If the activity has to be carried out, it will be done after determining whether there are breeding fish species in the area.
- The natural structure of the riparian vegetation will be preserved, which forms the spawning and sheltering area for many aquatic organisms.

If the bridge construction piers are built inside the stream bed or on the bank part, excessive sediment loading and destruction of the aquatic ecosystem may occur during construction. Downstream and in working areas, the fish spawning grounds may be destroyed. Excessive sediment loading can clog fish gills, hindering their respiratory function. For this reason, bridge piers will not be built inside stream beds or banks.

The planned interventions are expected to increase the sediment load in the river and creek systems. Especially in rainy periods, the increase in sediment due to erosion is very high, and aquatic organisms are used to this seasonally. There will be no interference to the stream bed under normal operating conditions. However, sedimentation that may occur as a result of unexpected effects may have some negative consequences. This increase in sediment has a particularly negative impact on fish. The sediment flowing to the lower parts of the activity area damages the fish's gills and deaths may occur due to insufficient respiration. Malnutrition and growth disorders can also be seen. In addition, undesirable results can be seen in terms of aquatic plants and phytoplankton organisms that cannot photosynthesize because intense sedimentation prevents sunlight from entering the water body for a certain period.

April and May are the breeding seasons of aquatic organisms. During this period, interference with aquatic systems will be minimized and/or avoided to the extent possible. The sediment that will be mixed with the stream due to an intervention in these months may cause some negativity. If the construction activities are carried out in the water body without changing the river bed, sediment traps give positive results. Apart from this, if it is necessary to intervene in the bed, it will be preferred to work on dry ground by changing the bed of the rivers and streams where the transitions will take place. If the geographical conditions allow, work will be done on dry ground by changing the direction of the river and stream in the transition zone. In this way, no damage will be done to the downstream part of the river and stream systems. After the transition process is completed, the flow direction of the river and stream will be given back to its old bed.

During the breeding season of fish species (April, May), no work will be conducted in creek beds; however, if it becomes necessary, the sensitivities of the region will be taken into account. These sensitivities will be clarified upon completion of all field studies, and the measures will be updated accordingly.

Machinery used in construction works will not go beyond a certain route, and unnecessary destruction will not be allowed because the strong vegetation in the riparian area is also important for many terrestrial organisms, especially amphibians and reptiles. In addition, plant communities and stony areas in riparian vegetation are suitable habitats for many organisms. Due to the dense bank vegetation of some stream and river systems, which are also given in the habitat descriptions, special attention will be paid during the breeding season. In areas where intervention is inevitable, it will be essential to take the precautions defined in the flora section regarding these areas.

The transition zones in the stream/river systems of the motorway route do not have steep slopes, and the riparian vegetation is relatively well known; therefore, no bank zone could cause erosion. However, the relevant personnel will give necessary information and warnings so that the machines do not cause bank disruption. In addition, after the completion of the transition construction, reinforcement works with rock blocks and/or other appropriate construction techniques will be applied to ensure the stability of the bank area if applicable

IX.8.2. Operation Phase

The main impact of the motorway projects during the operation phase is barrier effects and collisions. A variety of measures is designed to reduce the number of animals killed on or around transport infrastructure and eliminate the barrier effect. Measures to be taken for impacts on ecology and biodiversity during the operation phase are presented below.

Viaducts: Viaducts are particularly valuable to preserve ecosystems. They are favorable for invertebrates and small vertebrates, strongly linked to particular vegetation types, and hardly use underpasses without plant cover.

Culverts: Culverts for animals are primarily constructed as safe crossing points for mammals. They are a suitable solution, particularly in hilly areas or where the infrastructure is built on an embankment. Target species are usually mammals, and smaller mammals may also readily use these culverts. It has been determined that the culverts to be built within the Project's scope are suitable for mammal passages.

Fences: Fences will be built to prevent moving fauna species from entering the roads. They will mainly be constructed to reduce accidents due to collisions between large mammals and cars and reduce the number of smaller animals killed on the roads. The disadvantage of fences is that they increase the barrier effect. Therefore, where fences or other barriers are erected, it has to be ensured that the species concerned have enough opportunities to cross the road. In most cases, fences must therefore be combined with wildlife passages. They fulfil an essential role in guiding animals to the crossing points in these cases. When traffic safety is not an issue, fences will only be erected where animal mortality might threaten a population; otherwise, the barrier effect might have worse effects on the survival of the populations in the long term than the mortality due to traffic.

In general, wildlife fences will be only in places where the number of animals killed is high or a high risk of accidents involving wildlife. This is primarily the case along high-speed roads. Density fences will only be erected at high-risk spots on ordinary roads with low traffic.

Fences will always be built on both sides of a road. This is because the ends of the fences are danger points: animals may go round the end of the fence and get trapped on the road. Fences will therefore end at structures like bridges. Although only a stretch of the road is fenced in, they will be extended 500 m or more beyond the danger area. On roads with relatively little traffic, openings in fences can be provided at locations where animals can easily cross and where crossing animals are well visible to drivers.

For traditional wildlife fences, the lower half or lower third of the fence will have smaller mesh sizes to prevent small animals from passing through. Recommended spacing is as follows:

- Horizontal wire spacing: Bottom: 50-150 mm, Top: 150-200 mm
- Vertical wire spacing: 150 mm
- Wire thickness: At least 2.5 mm, made of rust-resistant material
- Bottom wire: Shall be secured to the ground to prevent animals from burrowing underneath. If the ground is uneven, it will be leveled to eliminate gaps.

Culverts and ditches along the fence shalll be carefully designed to prevent gaps that animals could pass through.

Within the scope of the Motorway Projects, fences will be used under the practices mentioned above to prevent animals from colliding with other vehicles on the road, especially in areas where vehicle traffic will be heavy. Fences will be implemented under General Directorate of Highways (KGM) approval to prevent wildlife-vehicle collisions

Warning Signs: Warning signs aim at influencing drivers' behaviour to reduce the number and severity of collisions between large mammals and cars. In addition, standard traffic signals will be

placed in areas where collisions often occur. Warning signs will be made with the approval of the General Directorate of Highways (KGM).

Lights: Road lights often attract insects and, consequently, bats or nocturnal birds that hunt them. This results in high mortality for the insects and their predators. Insensitive areas, the need to establish road lights will therefore be balanced against the consequences for nature. To prevent collisions of insects, sodium lights will be used.

IX.8.3. Risk-Impact-Measure Matrix

The potential risks and corresponding mitigation strategies for the Project is given in Table IX.47. This table outlines the necessary precautions for identified threats. However, unforeseen risks may arise during the project, making it essential to consult an expert in ecology throughout the Project's pre-construction, construction and operation phases.

In summary, in light of this information, the risks have been identified and mitigation measures have been developed following the United Nations Environmental Programme (UNEP) approach, which emphasizes developing conservation strategies that do not hinder economic growth and development. Provided that the recommended mitigation measures and precautions are properly implemented, the motorway project is not expected to have irreversible or unmanageable impacts on terrestrial and aquatic ecosystems.

IX.8.4. Monitoring

The effects of the activity on biodiversity and the mitigations taken are defined in this report. However, monitoring species and habitats' presence and population status is also essential. In this context, the biodiversity monitoring plan for the Motorway route is given in this section.

During monitoring, habitat losses under the Project will be assessed holistically, not only in terms of physical area contraction, but also in terms of structural integrity (e.g. stratigraphy, soil structure) and ecological functions (shelter, reproduction, pollination, ecological corridor role). Thus, not only quantitative but also qualitative losses will be analyzed and more effective strategies will be developed to prevent and/or compensate for impacts.

Ecosystem monitoring: It is necessary to determine the current situation by monitoring the effects of the motorway project on the ecosystem along its route. The most obvious effect of motorways on the ecosystem is habitat fragmentation. Therefore, it is necessary to determine whether the motorway project causes habitat fragmentation for any species. If such a situation is detected, this problem should be eliminated by adding an ecosystem bridge to the project. For this reason, a two-day field study is required three times a year (in spring, summer and autumn) during the project and for the 5-year period following the commissioning of the motorway.

Species monitoring: It is expected that rare and endangered species, especially endemic species, will be negatively affected during the implementation of the motorway project. It is necessary to decide whether the project had an impact on important species in the region, if so, to what extent these impacts are and whether any protection measures will be taken. For this reason, an evaluation was made by taking into consideration issues such as IUCN criteria, endemicity, international agreements, rarity, etc. Although two fish species (*Anguilla anguilla* - CR; *Cyprinus carpio* - VU) are under threat according to IUCN criteria, monitoring is not recommended because they are commercially fished species.

Among the species identified in the Project Area, seven plant species (*Eryngium kotschyi*, *Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis, Sideritis congesta*), one amphibian species (*Lyciasalamandra atifi*), two reptile species (*Lacerta pamphylica*; *Testudo graeca*), two bird species (*Neophron percnopterus*; *Streptopelia turtur*) two bat species (*Myotis capaccinii* and *Rhinolophus mehelyi*) and four fish species (*Capoeta antalyensis*; *Oxynoemacheilus eregliensis*; *Alburnus baliki*; *Pseudophoxinus fahrettini*) are recommended for monitoring (Table IX.45).

Further details regarding the specific areas where species monitoring will be conducted, as well as the duration of monitoring activities, are outlined in the Biodiversity Monitoring Plan (BMP) under the Biodiversity Monitoring and Evaluation Programme (BMEP)

Table IX.45 Recommended Monitoring Activities for Plant and Animal Species

Species	Status	Observation	Recommended Action	Time Period	Target	Indicator
Pyrus serikensis	Regional endemic; EN category in the IUCN List	Direct observation	The population status of the species in the field and its immediate surroundings will be monitored.	Monitoring activities will be conducted between April and September during the construction phase and for five years during the operational phase.	Reduce direct and indirect negative impacts	Conservation of the species and its habitat
Endemic Plant Species (*Eryngium kotschyi, Phlomis leucophracta, Phlomis lycia, Phlomis monocephala, Phlomis nissolii, Pyrus serikensis, Sideritis congesta*)	Regional endemic	Direct observation	The population status of the species in the field and its immediate surroundings will be monitored.	Monitoring activities will be conducted between April and September during the construction phase and for five years during the operational phase.	Preventing direct and indirect negative impacts	Conservation of the endemic species and its habitat
Lyciasalamandra atifi	EN category in the IUCN List	Direct observation	The population status of the species in the field and its immediate surroundings will be monitored. • In case of negative effects observed as a result of monitoring studies, recommendations and additional conservation strategies will be prepared.	Monitoring activities will be conducted between February and June during the construction phase.	Preventing direct and indirect negative impacts	Conservation of the species and its habitat
Lacerta pamphylica	Local endemic; LC in the IUCN List	Direct observation	The population status of the species in the field and its immediate surroundings will be monitored.	Monitoring activities will be conducted between March and September during the construction phase.	Preventing direct and indirect negative impacts	Conservation of the species and its habitat
Testudo graeca	VU category in the IUCN List	Direct observation	The population status of the species in the field and its immediate surroundings will be monitored. • In the first year of the operational phase, monitoring will be carried out, and based on the collected data; a decision will be made on whether to continue monitoring.	Monitoring activities will be conducted between March and September during the construction phase.	Preventing direct and indirect negative impacts	Conservation of the species and its habitat
Neophron percnopterus	EN category in the IUCN List	Direct observation	Monitoring the presence of the species within the site and its surroundings and determining its habitat use (transition, feeding, accommodation, reproduction, wintering, etc.).	Monitoring activities will be conducted between March and September during the construction	Preventing direct and indirect negative impacts	Conservation of the species and its habitat

Species	Status	Observation	Recommended Action	Time Period	Target	Indicator
				phase.		
Streptopelia turtur	VU category in the IUCN List	Direct observation	Monitoring the presence of the species within the site and its surroundings and determining its habitat use (transition, feeding, accommodation, etc.).	Monitoring activities will be conducted between March and September during the construction phase.	Preventing direct and indirect negative impacts	Conservation of the species and its habitat
Myotis capaccinii *Rhinolophus mehelyi*	VU category in the IUCN List	Direct observation	Monitoring the presence of the species within the site and its surroundings and determining its habitat use (e.g., migration, foraging, roosting, etc.). • In case of negative effects observed as a result of monitoring studies, recommendations and additional conservation strategies will be prepared.	Monitoring activities will be conducted in the quarry site and soil deposition areas during the construction phase, between March and October, when air temperatures exceed 15°C.	Preventing direct and indirect negative impacts	Conservation of the species and its habitat
Alburnus baliki *Capoeta antalyensis* *Oxynoemacheilus eregliensis* *Pseudophoxinus fahrettini*	Endemic (*Alburnus baliki, Oxynoemacheilus eregliensis)* Regional endemic (*Capoeta antalyensis, Pseudophoxinus fahrettini)* EN category in the IUCN List (*Alburnus baliki, Pseudophoxinus fahrettini)* VU category in the IUCN List (*Capoeta antalyensis, Oxynoemacheilus eregliensis)*	Direct observation	The population status of the species in the field and its immediate surroundings will be monitored.	Monitoring activities will be conducted between March and September during the construction phase.	Preventing direct and indirect negative impacts	Conservation of the species and its habitat

In line with IFC PS6 and international best practices, spring and autumn migration periods are critical for migratory birds. The current four-season dataset does not fully capture short-term stop-over or transit species. To address this, expanded monitoring of birds and bats is recommended throughout breeding, migration, and wintering periods. Monitoring should:

- Identify species presence and habitat use (e.g., passage, feeding, breeding).
- Inform adaptive management and protection measures.
- Guide decisions on which species require continued monitoring.

At the end of each monitoring year, findings should be evaluated to update management plans and scientifically justify any changes in monitoring priorities. This ensures effective, evidence-based biodiversity conservation throughout the project lifecycle.

IX.8.4.1. Migratory Bird Monitoring

In accordance with the International Finance Corporation's Performance Standard 6 (IFC PS6) and international best practices, the spring and autumn migration periods are recognized as critical timeframes for migratory bird species. While a four-season biodiversity dataset has been compiled, it presents limitations in adequately capturing transient species and short-term stopover populations that utilize the area primarily during these key migratory periods.

To address this gap, continued ornithological monitoring is planned during both the construction and operational phases of the project. This extended monitoring will specifically target the spring (March–June) and autumn (August–November) migration periods and will include:

- A total of 60 days of targeted ornithological monitoring per year (30 days in spring and 30 days in autumn).
- Implementation of fixed-point observations, mobile transect surveys, and flight monitoring using thermal imaging or binoculars, with a particular focus on raptor species.
- Evaluation of migratory species' area use, passage density, and habitat preferences during these periods.
- Additional assessment of breeding bird species, identification of breeding habitats, and an analysis of their spatial relationship with the highway alignment.

This expanded monitoring approach is designed to ensure comprehensive documentation of avian biodiversity and inform mitigation strategies in alignment with IFC PS6 requirements.

IX.8.4.2. Bat Monitoring

Monitoring of bat populations, particularly species listed as Vulnerable (VU) such as Rhinolophus mehelyi and Myotis capaccinii, is a critical component of biodiversity assessment for the project. These species are of conservation concern, and monitoring efforts must be designed to assess their distribution, population status, and habitat use in line with IFC Performance Standard 6 (PS6) and EUROBATS guidelines.

Bat monitoring activities will be focused on key habitats that may support roosting, foraging, or breeding populations. These habitats were given in Table IX.46.

Table IX.46 Habitats and Methods for Bat Monitoring

Habitat Type	Method
Quarry Areas	Acoustic transects; visual shelter control
Dump Sites	Insect abundance and feeding activity (Acoustic monitoring with batcorder)
Natural Caves	Guano/roost trace detection; sound recording with batcorder
Rock Crevices	Habitat use mapping; sound recording with batcorder
Stream Beds	Habitat use mapping; sound recording with mobile transects and batcorder

In accordance with IFC PS6, seasonal monitoring will be conducted during periods of peak bat activity to ensure accurate and meaningful ecological assessment. Monitoring will occur during at least two different seasons—preferably spring–summer and autumn—and will continue through both the construction and operation phases of the project. The monitoring program will be reviewed and updated using an Adaptive Management approach, allowing for responsive conservation actions based on emerging data.

As per EUROBATS Guidelines, the optimal monitoring window is between April and October, with peak bat activity typically occurring from May to August. The monitoring protocol will include the following components:

- Nighttime Acoustic and Visual Surveys: Monitoring will be conducted during twilight and nighttime hours, with data collection over a minimum of three consecutive nights at each monitoring location.
- Reproductive Colony Surveys (Late May – Early July): These surveys aim to identify maternity roosts and track the presence of lactating females and juvenile bats to determine breeding success and colony structure.
- Autumn Activity and Dispersal Surveys (August – October): These will evaluate post-breeding dispersal and potential migratory behavior, as well as habitat use during the late activity season.
- Wintering Habitat Assessment (January – February): Investigations during winter will focus on identifying critical hibernation sites such as caves and other subterranean refuges.

This comprehensive and seasonally-structured monitoring strategy will ensure that the ecological requirements of sensitive bat species are effectively integrated into project planning and management, in line with international conservation standards.

IX.8.5. Summary of Assessment and Residual Impacts

The assessment of impacts on natural habitats demonstrates that, altough moderate adverse effects are anticipated during the construction phase, these do not result in significant residual impacts once mitigation and habitat recovery measures are applied. Several factors contribute to this conclusion:

Limited Spatial Extent of Habitat Loss

The habitats within the Project footprint represent small proportions of the wider regional distribution. Maquis, garrigue, and coniferous forests especially are widespread across Antalya Province, and riparion corridors along major streams extend well beyond the Project Area. The proportions of these habitats directly affected by construction and operation activities are therefore minor relative to their availability in the wider landscape, reducing the permanent ecological fragmentation.

Low Level of Secondary Impacts

The air quality modelling prepared for the Project indicates that predicted concentrations of PM10, PM 2.5 and other pollutants during both construction and operation phases remain below national and IFC guideline threshold by a significant margin at the nearest natural habitats. This demonstrates that edge effects from dust, and emissions are negligible, and will not significantly degrade habitat quality.

Mitigation and Habitat Recovery Measures

As described in the Mitigation Measures section, a suite of measures will be implemented, including:

- Topsoil conservation and reuse to support natural regeneration of natural habitats.
- Where necessary active replanting with native species to accelerate recovery and stabilize soils.
- Habitat connectivity measures such as avoiding unnecessary fragmentation
- Pollution prevention controls
- Long-term ecological monitoring with adaptive management to address invasive species and ensure habitat recovery trajectories.

Ecological Resilience of Affected Habitat Types

The ecological characteristics of these Mediterranean habitats (all of them but especially maquis, garrigue, and phrygana) make them inherently resilient to disturbance. They are adapted to natural drivers such as grazing, fire, and drought, and exhibit strong regenerative capacity when topsoil and seed banks are preserved. As such, even temporary disturbances can be expected to regenerate to functional habitat conditions within a relatively short period following construction. The resilience of these habitats has been demonstrated over time, as they have repeatedly regenerated following frequent fires characteristic of the Mediterranean region, where such disturbances form a natural stage in their ecological succession cycle.

Much of the surrounding landscape remains continuous natural vegetation, and the motorway alignment with the protection areas consists of only modified habitats. Therefore, considering the relative scale of habitat disturbance in the regional context, the low levels of secondary effects confirmed by air quality modelling, the strong regenerative capacity of Mediterranean habitats, and the robust package of mitigation and recovery measures, the impacts on natural habitats are assessed as not significant after mitigation. Only maquis vegetation impact significance is evaluated as Medium (B2) due to the endangered species *Pyrus serikensis*.

Table IX.47 provides a summary of the ecology and biodiversity assessments. The significance of the identified impacts before and after mitigation measures are summarized in this table.

Table IX.47. Summary of the Ecology and Biodiversity Assessments

Impacted Ecosystem Component		Definition of Potential Impact	Type of Impact	Impact Magnitude						Sensitivity/ Value of Resource /Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts	Reason for Decrease in Significance
				Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude					
Land Preparation and Construction														
Terrestrial Habitats	S5 - Maquis, arborescent matorral and thermo-Mediterranean scrub	Habitat loss and habitat fragmentation Vegetation and topsoil removal Noise and dust pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Moderate (B)	High	High (B3)	• The intrusion of any invasive flora species into the Project Area and its surroundings will be prevented. For this purpose, vehicles used for vegetation clearance and/or plant transfer will be checked beforehand. • Project workers will not be allowed to bring any live animals or plants into the construction site to avoid the risk of pest/invasive species establishing in the Project Area. • Measures to reduce noise, dust, and air quality will be taken. • Project construction sites and access roads will be separated from other areas with appropriate KGM approved signboards, signs, and fences. Therefore, staff and vehicle access to the area will be limited to the construction site. • Construction waste generated due to project activities will be stored at designated storage areas, and then disposed of solid waste will not be allowed to be left in natural habitats. • Vegetation clearance will take place gradually, so fauna elements will be allowed to leave construction sites. • Topsoil storage and reuse for vegetation reinstatement. • Conduct post-construction rehabilitation to restore the natural structure of affected maquis and forest habitats. • Ecological restoration of disturbed areas post construction • Collect seeds from endemic species and deliver to a seed bank for ex-situ conservation. • Minimize human-induced disturbances and adhere to conservation guidelines throughout the Project Area.	Medium (B2)	Mitigation measures (invasive species control, phased clearance, fencing, waste management, topsoil reuse, and replanting) reduce disturbance and ensure restoration, making impacts temporary and localized.
	G1.1 - Riparian and gallery woodland, with dominant Alnus, Betula, Populus or Salix T3 - Coniferous forest T14 - Mediterranean and Macaronesian riparian forest S7.211 - Aegean *Sarcopoterium phrygana* S6 - Garrigue	Habitat loss and habitat fragmentation Vegetation and topsoil removal Noise and dust pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Moderate (B)	Medium	Medium (B2)		Low (B1)	Mitigation measures (invasive species control, phased clearance, fencing, waste management, topsoil reuse, and replanting) reduce disturbance and ensure restoration, making impacts temporary and localized. Therefore, significance is reduced from Medium to Low..
	J1 - Buildings of cities, towns and villages V1 - Arable land and market gardens	Habitat loss and habitat fragmentation Vegetation and topsoil removal Noise and dust pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Moderate (B)	Low	Low (B1)		Low	Impacts are already minor by nature. Mitigation keeps them controlled and ensures they do not escalate, so the rating stays Low.
Aquatic Habitats	C2 - Surface running waters	Habitat loss and habitat fragmentation Water pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Moderate (B)	Medium	Medium (B2)	• During construction, mixing any chemical substances that is used in the construction area, in aquatic ecosystems will be prevented • Excavation materials will not be dumped onto riverbeds	Low (B1)	Risk of water contamination and habitat alteration reduced throuh strict waste/chemical controls and no dumping policy. Impacts become limited and reversible.
(Flora)	*Pyrus serikensis*	Vegetation and topsoil removal Habitat loss and habitat fragmentation Noise and dust pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Moderate (B)	High	High (B3)	• Seeds of the species will be collected and delivered to the Seed Gene Bank. • Monthly monitoring between April and August will be conducted in the flowering period for these species	Medium (B2)	Mitigation reduces the risk of permanent loss. Lowering significance from High to Medium.
	Eryngium kotschyi *Phlomis leucophracta* *Phlomis lycia* *Phlomis monocephala* *Phlomis nissolii* *Sideritis congesta* *Barlia robertiana*	Vegetation and topsoil removal Habitat loss and habitat fragmentation Noise and dust pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Moderate (B)	Low	Low (B1)		Low	Impacts are already minor, mitigation ensures they remain controlled, so the rating stays low.
(Amphibians)	*Lyciasalamandra atifi*	Habitat loss and habitat fragmentation	Adverse	Widespread	Long	Low	Irreversible	One-off	Moderate (B)	High	High (B3)	• Due to habitat loss, noise, dust formation, and vehicle-human traffic, construction activities will be carried out gradually to provide birds and mobile fauna species with time and energy to leave the area. • At-grade crossings will be established to facilitate movement between the fragmented habitats. • The construction sites will be fenced to prevent the entry of fauna species. In	Medium (B2)	Gradual works, safe crossings, fencing, restricted traffic and monitoring reduce mortality and habitat fragmentation, lowering significance from High to Medium.
(Reptiles)	*Testudo graeca*	Vegetation and topsoil removal	Adverse	Widespread	Long	Low	Irreversible	One-off	Moderate (B)	Medium	Medium (B2)		Low (B1)	Mitigation limits disturbance and ensures impacts remain localized and reversible, reducing significance from Medium to Low.

Impacted Ecosystem Component		Definition of Potential Impact	Type of Impact	Impact Magnitude						Sensitivity/ Value of Resource /Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts	Reason for Decrease in Significance
				Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude					
	Lacerta pamphylica	Habitat loss and habitat fragmentation								High	High (B3)	addition, traffic will be restricted in the Project Area, except for pre-designed roads, to avoid animal destruction. • Construction activities involving ground disturbance will ideally be scheduled outside the hibernation period or conducted with caution in areas where hibernating reptiles may be present. • Warning signs will be used along the Motorway with the approval of KMG. • To prevent collisions of insects the use of sodium lights will be used. • Bird nests, and moist habitats will be monitored during the construction and operation phases, and additional measures will be determined if necessary. • Monitoring will be done during the construction and operation. • Project personnel will be informed and trained in the aquatic environment. • Confirming species presence for *Lacerta pamphylica*, relocating individuals pre-construction.	Low (B2)	Scheduling, fencing, and species-specific measures reduce long-term risks. Considering species population being stable and IUCN category being "LC", these measures are bringing significance down from High to Low.
	Anatololacerta ibrahimi *Ablepharus anatolicus* *Blanus aporus*									Low	Low (B1)		Low	Already minor; mitigation ensures no escalation, so significance remains Low.
(Birds)	*Neophron percnopterus*	Vegetation and topsoil removal Habitat loss and habitat fragmentation	Adverse	Widespread	Long	Low	Irreversible	One-off	Moderate (B)	High	High (B3)		Low (B2)	Targeted measures (crossings, fencing, monitoring) effectively reduce major risks, lowering significance from High to Low.
	Streptopelia turtur		Adverse	Widespread	Long	Low	Irreversible	One-off	Minor (C)	Medium	Low (C2)		Low (C1)	Impacts are already small; controls and monitoring reduce them further, shifting significance from Low (C2) to Low (C1).
	Accipiter nisus *Aquila chrysaetos* *Buteo buteo* *Buteo rufinus* *Circaetus gallicus* *Circus aeruginosus* *Circus cyaneus* *Circus macrourus* *Ciconia ciconia* *Ciconia nigra* *Falco columbarius* *Falco peregrinus* *Falco subbuteo* *Falco tinnunculus*								Minor (C)	Low	Low (C1)		Low	Impact is negligible; mitigation maintains low level with no change.
(Mammals)	*Myotis capaccinii* *Rhinolophus mehelyi*	Vegetation and Topsoil Removal Habitat Loss and Habitat Fragmentation	Adverse	Widespread	Long	Low	Irreversible	One-off	Moderate (B)	Medium	Medium (B2)		Low (B1)	Mitigation minimizes extent and duration of impacts, reducing significance from Medium to Low.
(Freshwater species)	*Anguilla anguilla* *Alburnus baliki* *Capoeta antalyensis* *Pseudophoxinus fahrettini* *Pseudophoxinus battalgilae*	Habitat Loss and Habitat Fragmentation Water Pollution	Adverse	Widespread	Long	Medium	Irreversible	One-off	Minor (C)	High	Medium (C3)	• Excavation materials will not be dumped onto a riverbed. • Mixing any chemical substances used in the construction area, waterbed, and/or aquatic ecosystems will be prevented. • The natural structure of the riparian vegetation will be preserved, which forms the spawning and sheltering area for many aquatic organisms.	Low (C2)	Strict controls on waste, chemicals, and sediment, plus seasonal restrictions and riparian protection, significantly reduce risks to aquatic habitats, lowering significance from High to Low.

Impacted Ecosystem Component		Definition of Potential Impact	Type of Impact	Impact Magnitude						Sensitivity/ Value of Resource /Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts	Reason for Decrease in Significance
				Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude					
	Cyprinus carpio *Capoeta caelestis* *Cobitis battalgilae* *Oxynoemacheilus eregliensis* *Alburnus escherichii* *Squalius anatolicus* *Squalius fellowesii* *Salmo ekmekciae*									Medium	Low (C2)	• Especially during the breeding season of fish species (April and May), any intervention on riverbeds will be prevented. Viaduct or bridge construction activities will be conducted in months other than April-May, as turbidity can have lethal effects on fish eggs. If the activity has to be carried out, it will be done after determining whether there are breeding fish species in the area. • Sediment traps will be used to prevent the negative impact of the sediment that construction activities will generate. • Strengthening works will be done with certain rock blocks to ensure the stability of the coast. • Project activities will be limited to designated areas to avoid direct impacts. • Monitoring will be done during the construction and operation. • Project personnel will be informed and trained in the aquatic environment.	Low (C1)	Mitigation limits pollution and disturbance, protecting aquatic species and spawning areas, reducing significance from Medium to Low.
Operation														
Terrestrial Habitats	S5 - Maquis, arborescent matorral and thermo-Mediterranean scrub	Noise and pollution Alteration of soil chemistry	Adverse	Widespread	Long	Low	Irreversible	Continuous	Moderate (B)	High	High (B3)	• Maintaining vegetation buffers to reduce noise/light disturbance • Monitor and control of any invasive species • Ecological restoration of disturbed areas post construction • Topsoil storage and reuse for vegetation reinstatement	Medium (B2)	Vegetation buffers and invasive species control reduce disturbance, lowering significance from High to Medium.
	G1.1 - Riparian and gallery woodland, with dominant Alnus, Betula, Populus or Salix T3 - Coniferous forest T14 - Mediterranean and Macaronesian riparian forest S7.211 - Aegean *Sarcopoterium phrygana* S6 - Garrigue	Noise and pollution Alteration of soil chemistry	Adverse	Widespread	Long	Low	Irreversible	Continuous	Moderate (B)	Medium	Medium (B2)		Low (B1)	Noise/light impacts are localized and controlled by vegetation buffers, reducing significance to Low.
	J1 - Buildings of cities, towns and villages V1 - Arable land and market gardens	Noise and pollution Alteration of soil chemistry	Adverse	Widespread	Long	Low	Irreversible	Continuous	Moderate (B)	Low	Low (B1)		Low (B1)	Already minor; mitigation maintains impacts at Low.
Aquatic Habitats	C2 - Surface running waters	Water pollution	Adverse	Widespread	Long	Low	Irreversible	Continuous	Minor (C)	Medium	Medium (B2)	• Prevent chemical runoff	Low (B2)	Runoff prevention minimizes water pollution risk, keeping impacts Low.
(Amphibians)	*Lyciasalamandra atifi*	Mortality due to vehicle collision Light and noise disturbance	Adverse	Widespread	Long	Low	Irreversible	Continuous	Minor (C)	High	High (B3)	• Installing culverts, underpasses, overpasses, viaducts, and bridges for safe crossing and fences to prevent fauna to enter the motorway • Warning signs will be used along the Motorway with the approval of KMG. • To prevent collisions of insects the use of sodium lights will be used. • Bird nests, and moist habitats will be monitored during the construction and operation phases, and additional measures will be determined if necessary. • Monitoring will be done during the construction and operation.	Low (B2)	Culverts, fencing, and monitoring reduce collision risk and habitat fragmentation, lowering significance from High to Low.
(Reptiles)	*Testudo graeca*	Mortality due to vehicle collision	Adverse	Widespread	Long	Low	Irreversible	Continuous	Moderate (B)	Medium	Medium (B1)		Low (B2)	Culverts, fencing, and monitoring reduce collision risk and habitat fragmentation, lowering significance from Medium to Low.
	Lacerta pamphylica		Adverse	Widespread	Long	Low	Irreversible	Continuous	Moderate (B)	High	High (B3)		Low (B2)	Safe crossing structures and fencing minimize severe risks, reducing significance from High to Low.
	Anatololacerta ibrahimi *Ablepharus anatolicus* *Blanus aporus*		Adverse	Widespread	Long	Low	Irreversible	Continuous	Moderate (B)	Medium	Medium (B2)		Low (B1)	Crossing measures reduce residual mortality and fragmentation, lowering significance to Low.
(Birds)	*Neophron percnopterus*	Mortality due to vehicle collision Disturbance from light/noise	Adverse	Widespread	Long	Low	Irreversible	Continuous	Minor (C)	High	High (B3)		Low (B1)	Use of sodium lights prevents insect attraction and by this, preventing birds attraction and reduces disturbance, lowering significance to Low.
	Streptopelia turtur		Adverse	Widespread	Long	Low	Irreversible	Continuous	Minor (C)	Low	Low (B1)		Low (B1)	Use of sodium lights prevents insect attraction and by this, preventing birds attraction and reduces disturbance, keeping the significance Low.

Impacted Ecosystem Component		Definition of Potential Impact	Type of Impact	Impact Magnitude						Sensitivity/ Value of Resource /Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts	Reason for Decrease in Significance
				Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude					
	Accipiter nisus *Aquila chrysaetos* *Buteo buteo* *Buteo rufinus* *Circaetus gallicus* *Circus aeruginosus* *Circus cyaneus* *Circus macrourus* *Ciconia ciconia* *Ciconia nigra* *Falco columbarius* *Falco peregrinus* *Falco subbuteo* *Falco tinnunculus*								Minor (C)	Low	Low (C1)		Low	Already minor; culverts and fencing maintain low-level impacts.
(Mammals)	*Myotis capaccinii* *Rhinolophus mehelyi*	Mortality due to vehicle collision Light pollution Noise pollution	Adverse	Widespread	Long	Medium	Irreversible	Continuous	Minor (C)	Medium	Medium (C2)	• Installing culverts and/or underpasses for safe crossing • Monitoring of bat species populations • Usage of sodium lights • Reporting of fauna casualties	Low (C1)	Crossing structures, monitoring, and lighting reduce collision and disturbance risks, lowering significance from Low (C2) to Low (C1).
(Freshwater species)	*Anguilla anguilla* *Alburnus baliki* *Capoeta antalyensis* *Pseudophoxinus fahrettini* *Pseudophoxinus battalgilae*	Water Pollution	Adverse	Widespread	Long	Low	Irreversible	Continuous	Minor (C)	Low	Low (C1)	• Prevent chemical runoff	Low (C1)	Runoff prevention avoids water pollution, maintaining already minor impacts at Low.
	Cyprinus carpio *Capoeta caelestis* *Cobitis battalgilae* *Oxynoemacheilus eregliensis* *Alburnus escherichii* *Squalius anatolicus* *Squalius fellowesii* *Salmo ekmekciae*		Adverse	Widespread	Long	Low	Irreversible	Continuous	Minor (C)	Medium	Low (C2)	• Prevent chemical runoff	Low (C1)	Preventing chemical runoff further reduces pollution risks, shifting significance from Low (C2) to Low (C1).

Even with careful site planning and the proposed mitigation measures, some residual impacts remain for maquis habitat, *Pyrus serikensis*, and *Lyciasalamandra atifi*.

The maquis habitat qualifies as Critical Habitat due to its high biodiversity value, ecological integrity, and the presence of restricted-range and endemic species. It provides essential ecosystem services and contributes to habitat connectivit. Even after the mitigations applied, some fragmentation and degradation for this habitat remains regarding sensitive species such as *Pyrus serikensis.*

For *Pyrus serikensis*, its limited range and small population size increase its vulnerability to habitat loss and fragmentation, considering the declining population of the species and the loss of suitable habitat for it, mitigations cannot fully reduce residual impacts.

For *Lyciasalamandra atifi*, an endangered species with a highly restricted range and dependence on specific karstic microhabitats, residual risk persists. Although not recorded directly within the project area, its conservation status and declining population make it highly sensitive to even small-scale habitat disturbance.

Further details on these residual effects and species-specific measures are provided in the BAP document.

.

IX.9. Ecosystem Services

Ecosystem services are the many and varied benefits provided to people by the natural environment and healthy ecosystems. The services provided by each ecosystem are unique and vary. According to the 2006 Millennium Ecosystem Assessment (MA), ecosystem services are the benefits that people derive from ecosystems. The MA also defined four categories of ecosystem services (support, provision, regulation, and cultural) discussed below.

Table IX.48. Ecosystem Services

Provisioning Services	**Relevance to Study Area**
Agricultural lands and fruit gardens provide services for people to feed	Priority 1
Flowing and stagnant water supplies provide water for both natural animals, and these waters are used to irrigate agricultural areas. In addition, these water resources regulate the water regime in the region.	Priority 1, Priority 2
Natural and plantation forests constitute both feeding, nesting and breeding areas for many birds, mammals, reptiles and insect species.	Priority 1, Priority 2
Regulating Services	**Relevance to Study Area**
Plant cover contributes to the prevention of floods by controlling erosion.	Priority 2
Due to the vegetation cover, rainwater does not flow into the stream, helping to submerge the water, at the same time reducing sediment transport to the lake and the seas.	Priority 2
Cultural Spiritual, and Recreational Services	**Relevance to Study Area**
Natural wooded areas are suitable for people to rest.	Priority 2
Natural forests provide lovely landscaping views.	Priority 2
Meadow-pasture areas provide grazing for livestock.	Priority 2
Cultural Spiritual, and Recreational Services	**Relevance to Study Area**
Using carbon dioxide through plant cover and trees, the oxygen needed for mankind is produced.	Priority 1, Priority 2
As natural habitats form the habitats of critical species, they have a very important mission in terms of species sustainability.	Priority 1, Priority 2

IX.9.1. Provisioning Services

A portion of the area designated for motorway construction under the project is currently used for food production. However, the area is not utilized for other supply services such as water and wood, genetic resources, or medicinal purposes. A part of the land where the motorway will be built will lose its agricultural function, including fields, gardens, and greenhouses, as it will be covered with asphalt and concrete. However, since only a very small portion of the agricultural area will be lost, it can be argued that the resulting loss of supply services is negligible.
Additionally, some forested and shrubland areas have been selected for the storage of excavation materials. As these areas will be used for this purpose, they will lose their natural characteristics. However, these areas are considered to be poor in terms of genetic resources and medicinal and aromatic flora elements. Therefore, it can be argued that the Project Area has low importance in terms of providing supply services. Furthermore, considering that only a very small area will lose its natural characteristics due to the project, it can be asserted that the project will not create a significant negative impact on supply services.

IX.9.2. Regulating Services

A large portion of the area designated to be converted into a motorway consists of anthropogenically altered agricultural lands. The regulatory ecosystem services in these areas, such as climate regulation, pollination, flood control and other natural disaster regulation, and water purification, have already been disrupted. Therefore, no significant loss in terms of regulating services is expected in these areas due to the implementation of the project.

A part of the Project Area is located in natural environments. Due to the temporary or permanent loss of the natural characteristics of these areas, the ability to provide support services will be eliminated or disrupted. Therefore, if the areas not covered by asphalt or concrete are rehabilitated and restored to their former state, the loss in support services can be compensated. The region has a rapid renewal capacity in terms of its climatic and floral characteristics. Therefore, if a good rehabilitation plan is prepared and implemented, the loss of ecosystem regulation services may be compensated.

IX.9.3. Cultural Services

Türkiye's Mediterranean coastline holds high value in terms of cultural services. Indeed, due to these characteristics, it is one of the most popular regions for both domestic and international tourists. Antalya province hosts over 15 million foreign tourists annually. A large portion of the area along the project route consists of agricultural lands. However, the remaining natural areas are not among the preferred regions in terms of cultural, recreational, and aesthetic values. Therefore, during the construction and operation of the motorway, it is unlikely that it will cause any negative impact in terms of cultural services.

IX.9.4. Supporting Services

Supporting services are related to the self-sustaining functions of habitats and, consequently, affect survival. These services include photosynthesis, the water cycle, and nutrient cycles. If the project is implemented, a portion of the area will be covered with asphalt and concrete, leading to a negative impact on these services. Additionally, the loss of natural characteristics in forested and shrubland areas designated for soil storage will result in a decline in supporting services.

To compensate for this loss, it is possible to mitigate the negative impact by implementing a rehabilitation program to restore the degraded areas to their original state. Therefore, identifying species lists in degraded areas and using these species for rehabilitation will help restore the ecosystem’s supporting services.

IX.10. Summary of Ecology and Biodiversity

Based on the habitat structure in and around the Project Area, it was determined that the area hosts 221 plant species, 29 fish species, five amphibians, 25 reptiles, 124 bird species (both native and migratory), and 46 mammal species, representing the area's biodiversity.

While some degree of habitat degradation is anticipated in the natural areas surrounding the Project Area, the overall impact on natural habitats is expected to be low. This is primarily due to the limited presence of vegetation other than cultivated plant species, as the land is predominantly used for agricultural purposes. Thus, it is determined that the change in the habitat quality of the area will cause some habitat loss in terms of shelter and feeding of animal species that constitute wildlife.

Considering the location and ecological characteristics of the motorway route, the plant species within the Project Area, along with the fish, amphibians, reptiles, birds, and mammals observed in the region, are generally composed of widely distributed species. However, some endemic species are also present, although they are not considered to be strictly dependent on the Project Area for their survival.

Considering the size and location of the Project Area, the overall environmental impact to limit the life of fauna elements during the activities, preventing their feeding, breeding and movement is expected to be low. This is primarily because the habitat along the motorway route closely resembles that of the surrounding areas, minimizing the potential for significant ecological disruption. Habitat similarity creates an alternative and advantage for faunistic species. Most of the fauna elements move to safe habitats as soon as possible due to their mobility. To mitigate habitat fragmentation resulting from the motorway construction, the implementation of wildlife crossings has been proposed. These structures are designed to maintain ecological connectivity by allowing animals to safely traverse the roadway, thereby reducing the risk of wildlife-vehicle collisions and supporting biodiversity conservation.

Since a large portion of the project site consists of agricultural land, where vegetation is either absent or highly modified, minor contraction of natural habitats in the surrounding area is anticipated. Therefore, some habitat loss is expected for wildlife species dependent on vegetation for shelter or food.

However, certain sections of the motorway pass through partially degraded or intact maquis and forested areas, making some biodiversity impacts inevitable for the habitats and some species. To address this, potential impacts for these ecological components have been identified, and mitigation measures have been developed. By implementing risk assessment matrices and mitigation strategies, it is possible to reduce potential impacts on ecology during both the construction and operational phases of the project.

In addition, by taking into account the risk assessment matrices and recommendations, possible impacts on the ecosystem during the installation and operation phases of the Project will be reduced. Recommended monitoring studies will ensure detection of residual impacts and negative effects that may arise during the process and intervention to eliminate the negativities.

Detailed mitigation measures and Biodiversity Monitoring and Evaluation Programme (BMEP) regarding priority habitats and species are given in the Biodiversity Management Report (BMP). Biodiversity net loss and net gain calculations which given in detail within the scope of Biodiversirty Action Plan (BAP), indicate that the project will result in net biodiversity loss. To compensate for this loss, additional mitigation and offset strategies have been developed and implemented, ensuring that the Project's impact is managed based on scientific principles. With such strategies it's possible to achieve no net loss and even net gain.

X. AIR QUALITY AND CLIMATE CHANGE

In this section, the potential impacts of the Project on air quality of the region and two-way relationship between the Project and climate change are assessed. Within this scope, the construction and operation phases of the Project are taken into consideration and impacts are evaluated separately. Air quality modeling studies have been conducted to assess the impacts on air quality. This chapter includes/will include the following:

- National (Turkish), EU (directives and regulations), and international (IFC Performance Standards) air quality requirements and standards
- Baseline air quality,
- Assessment and quantification of potential emissions related to the Project,
- Air quality modeling with AERMOD software for the construction and operation phases of the Project taking into account local meteorological data and topography of the region,
- Assessment of potential impacts on air quality,
- Mitigation measures regarding air quality,
- Residual impacts on air quality,
- Meteorological and climatic conditions of the Project Area,
- Assessment of potential impacts regarding climate change and relevant mitigation measures.

X.1. Air Quality

Air pollution can be defined as pollutants emitted from various sources reaching the level that affects human health and the environment negatively. Main sources that result in air pollution are anthropogenic sources such as vehicle traffic, industrial activities, domestic heating and overuse of natural resources.

Main pollutants emitted from motorway projects are nitrogen oxides (NO_x, combination of NO_2 and NO), particulate matter (PM_{10} and $PM_{2.5}$), carbon monoxide (CO), carbon dioxide (CO_2), and volatile organic compound (VOC). PM_{10} and $PM_{2.5}$ are expected to be emitted mainly during construction phase of the Project as a result of material extraction and supply, cut and fill operations and storage/retrieval of excavated material.

Particles can vary in size and composition. PM_{10} (particulate matter with aerodynamic diameter smaller than 10 µm) standard is set to define the particles that people are likely to inhale, and PM_{10} has become the general measure of particulate matter. In this sense, generally limit values are defined for PM_{10}. In addition to PM_{10}, IFC standards also have limitations for $PM_{2.5}$ (particulate matter with aerodynamic diameter smaller than 2.5 µm) parameter.

Other potential pollutants such as NO_X, CO, CO_2, and VOC are expected to arise from the operation of construction machinery and equipment during construction phase and traffic flow during operation phase of the Motorway. These pollutants are predominantly generated from fossil fuel usage for energy needs.

X.1.1. Assessment Methodology and Data Sources

X.1.1.1. Regulatory Framework

Regulation on Assessment and Management of Air Quality (RAMAQ)

Regulation on Assessment and Management of Air Quality was published on 06.06.2008 in Official Gazette No 26898. The purpose of this regulation is to define and set air quality targets in order to prevent or mitigate the negative impacts of air pollution on human health and environment, to assess air quality with defined methods and criteria, to sustain existing conditions in areas where air quality is good, to gather information about air quality and to inform the public about warning threshold levels.

In this regulation, short and long term limit values of various pollutants are defined for the harmonization to European Union (EU) environmental legislation. However, a transition period is proposed for the application of these limit values. In addition to the limit values, warning threshold levels for air pollutants are identified.

Industrial Air Pollution Control Regulation (IAPCR)

The Industrial Air Pollution Control Regulation, published on 03.07.2009 in Official Gazette No 27277, aims to control emissions in form of smoke, dust, gas, vapor and aerosol generated as a result of industrial activities and energy generation, to protect human and environment from pollution in receiving environment, to prevent negative impacts of air pollution on public and ensure that these effects do not arise.

According to the regulation, the limit values from stack and non-stack sources that require the calculation of the contribution values to air pollution in case of exceeding are provided. According to IAPCR Appendix 2 Table 2.1 for dust emissions the limit value from stack sources is 10 kg/hr, from non-stack sources 1 kg/hr. If the dust emissions exceed this limit value, the air quality contribution value should be calculated.

Emissions generated from the Project activities will be calculated and compared with the regulatory limits. If the calculated emission amount exceeds the regulatory limit value, modeling study will be conducted and the air quality contribution value will be estimated.

Regulation on Monitoring of Greenhouse Gas Emissions

The Regulation on Monitoring of Greenhouse Gas Emissions was published on 17.05.2014 in Official Gazette No 29003. The purpose of the regulation is to define procedures and principles for monitoring, reporting and verification of greenhouse gas emissions for a list of activities considered within the scope of the regulation.

X.1.1.2. Air Quality Standards

This subsection provides an overview of the national and international ambient air quality standards applicable to the assessment of air quality.

Turkish Legal Requirements

Ambient air quality is regulated in Türkiye by the Regulation on Assessment and Management of Air Quality (RAMAQ). Appendices I and I-A of this regulation provide limit values for various pollutant. The transition intervals to reach the target values are also defined in these appendices.

Air quality standards are defined in the Regulation on Assessment and Management of Air Quality (RAMAQ) published on 06.06.2008 in Official Gazette No 26898 and Industrial Air Pollution Control Regulation (IAPCR) published on 03.07.2009 in Official Gazette No 27277 (Amendment: Date, 06.10.2020; Official Gazette No, 31296). Ambient air quality limit values for various pollutants defined in Turkish regulations are presented in Table X.1. The standards in Table X.1 are the target values for 2024 and further years.

Table X.1 Turkish Regulations: Ambient Air Quality Limit Values

Parameter	Duration	Unit	Limit Value*
SO_2	Hourly (cannot be exceeded more than 24 times in a year)	**($\mu g/m^3$)**	350
	24 hour (cannot be exceeded more than 3 times in a year)	**($\mu g/m^3$)**	125
	Long term limit	**($\mu g/m^3$)**	60
	Annual and winter season (from 1 October to 31 March)	**($\mu g/m^3$)**	20
NO_2	Hourly (cannot be exceeded more than 18 times a year)	**($\mu g/m^3$)**	200
	Annual	**($\mu g/m^3$)**	40
PM_{10}	24 hour (cannot be exceeded more than 35 times a year)	**($\mu g/m^3$)**	50
	Annual	**($\mu g/m^3$)**	40
CO	8 hour daily maximum	**($\mu g/m^3$)**	10,000
Total VOC**	Hourly	**($\mu g/m^3$)**	280
	24-hour	**($\mu g/m^3$)**	70
In the settled dust	Pb and its compounds (long term limit value)	**mg/m^2day**	250
	Cd and its compounds (long term limit value)	**mg/m^2day**	3.75
	Tl and its compounds (long term limit value)	**mg/m^2day**	5

* *Regulation on Assessment and Management of Air Quality (RAMAQ)*
** *Industrial Air Pollution Control Regulation (IAPCR)*

IFC Standards

IFC standards and requirements will apply to the Project. The IFC General EHS Guidelines – Environmental Air Emissions and Ambient Air Quality (2007) refer to the World Health Organization (WHO) Ambient Air Quality Guidelines for recommended limit values. These limit values are presented in Table X.2.

Table X.2. IFC Standards: Ambient Air Quality Limit Values

Parameter	Duration	Guideline Value (µg/m³)*
SO_2	10 minute	500
	24 hour	20
NO_2	Hourly	200
	Annual	40
PM_{10}	24 hour	50
	Annual	20
$PM_{2.5}$	24 hour	25
	Annual	10

** Environmental, Health and Safety Guidelines, General EHS Guidelines: Environmental, Air Emissions and Ambient Air Quality*

EU Regulations

EU air quality standards and requirements will apply for the Project. The EU Ambient Air Quality Directives – Directive 2008/50/EC and Directive 2004/107/EC – establish legally binding limit values and target values for key air pollutants to protect human health and the environment. These standards apply over different averaging periods. In addition, the newly adopted Directive (EU) 2024/2881 of the European Parliament and of the Council of 23 October 2024 on ambient air quality and cleaner air for Europe (see Table 2) strengthens and updates the existing framework by setting more stringent air quality standards and reinforcing provisions on public information and air quality plans. The relevant EU air quality limit values are presented in Table X.3.

Table X.3 EU Regulations: Ambient Air Quality Limit Values*

Parameter	Duration	Guideline Value (µg/m3)*	Permitted Exceedances / Notes
Particulate Matter (PM_{10})	24-hour average	50 µg/m³	Not to be exceeded more than 35 times/year
	Annual average	40 µg/m³	
Particulate Matter ($PM_{2.5}$)	Annual average	25 µg/m³	
Nitrogen Dioxide (NO_2)	1-hour average	200 µg/m³	Not to be exceeded more than 18 times/year
	Annual average	40 µg/m³	To be reduced to 20 µg/m³ by 2030
Sulfur Dioxide (SO_2)	1-hour average	350 µg/m³	Not to be exceeded more than 24 times/year
	24-hour average	125 µg/m³	Not to be exceeded more than 3 times/year
Carbon Monoxide (CO)	Maximum daily 8-hour mean	10 mg/m³	
Lead (Pb)	Calendar Year	0,5 µg/m³	
Cadmium (Cd)	Calendar Year	5,0 ng/m³	

*http://data.europa.eu/eli/dir/2024/2881/oj

X.1.1.3. Significance Criteria

The significance criteria for the impacts on air quality will be determined, as high, medium or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter IV ("ESIA Methodology") are used for the determination of the magnitude of impact on the air quality, while sensitivity/value criteria to be used in the scope of impact assessment is summarized in Table X.4.

Table X.4. Criteria for Sensitivity/Value of Resource/Receptor

Ecosystem Component	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Human Receptors	Areas densely populated with residences and have poor air quality*.	Areas densely populated with residences and have good air quality* Dams for drinking water purpose.	Areas with dense work places/ industrial areas and/or not densely populated with residences. Dams for irrigation and energy production purpose.
Ecological Receptors	-**	Forests with ecological function	Forests with social and cultural and economic function,

** Good and poor air quality of receptors is determined according to baseline air quality measurements.*

***For high sensitivity, "National/Internationally Protected Areas" was evaluated and it's been determined that air impacts have minimal effects for this receptors. Therefore this cell was left empty.*

Evaluation of magnitude of impacts will be based on percentage of exceedance of air quality standards defined in the Regulation on Assessment and Management of Air Quality. Magnitude of impact is defined as low, medium, and high according to the results of modeling study's comparisons with the Turkish air quality limit values (see Table X.5). This approach applies to the exceedance of any pollutant for which the air quality standard is set, meaning that if the modeled concentration of PM_{10}, $PM_{2.5}$, NO_2, SO_2, CO, Settled Dust and VOC or any regulated pollutant exceeds its respective limit, the magnitude of impact is classified according to the percentage of exceedance.

Table X.5. Impact Magnitude Criteria

Magnitude of Impact	Exceedance of Air Quality Standard
Low	0-25 %
Medium	25-50 %
High	>50 %

X.1.1.4. Air Quality Modeling

In this study, the latest version of the AERMOD dispersion model (version 19191), published by the US EPA, was used. AERMOD is an internationally recognized model widely used by researchers and regulatory authorities to estimate air pollutant concentrations. The modeling was carried out using the BREEZE interface (version 7.7), which supports predictions of hourly, daily, and annual Ground Level Concentrations (GLCs) based on dynamic input data. AERMOD handles various emission sources—including point, volume, and area sources and considers factors such as turbulence, terrain

complexity, and meteorological conditions. The "Emission Estimation Technique Manual for Mining (Version 3.1)," prepared for the Australian National Pollutant Inventory, was referenced for the calculation of dust emissions. As a specific national set of emission factors for these activities is not available in Türkiye, an internationally accepted methodology was utilized.

The referenced Australian manual was chosen because it uses the globally recognized US EPA AP-42 standard as its foundational source—drawing most of its emission factors directly from AP-42 as stated in its appendix—while also validating and improving upon that baseline with actual field measurements.

The grid area defined as the study area for this study was determined by reference to the domain specified in IAPCR for the modeling study. In accordance with the Regulation on the Control of Industrial Air Pollution (IAPCR), the “facility impact area” is defined as the area within a radius equivalent to 50 times the stack height from the emission source, or, for sources with an effective emission height less than 30 meters, as a 2 km × 2 km square area centered on the source. For area sources with a surface distribution greater than 0.04 km², the impact area is also defined as a square with a 2 km edge length, centered on the source.

The model operates within a user-defined grid system and performs calculations at the corner points of each grid cell. It uses four main input data types: hourly surface meteorological data, upper atmospheric sounding data, terrain and land use data for the receptor grid, and detailed emission source parameters. AERMET and AERMAP are used for meteorological and terrain preprocessing, respectively. Model outputs are suitable for creating distribution maps to assess air quality under different scenarios (e.g., varying emission sources, fuel qualities, or seasonal conditions).

The modeling process involves defining the dispersion area, dividing it into 250×250 m grids, assigning receptor points, and inputting one year of meteorological data. After inputting this data, the model calculates pollutant concentrations in ambient air on an hourly, daily, and annual basis.

Air quality modeling was carried out under multiple scenarios to assess the dispersion and ground-level concentrations of pollutants emitted during both the construction and operation phases of the motorway project. Air Quality Modeling Report is given in Annex 6. Each scenario corresponds to a specific section of the route and pollutant type, as outlined below:

Construction Phase:

- Scenario 1: PM_{10} emissions from construction activities in Section 1, including blasting, material handling at quarries, and operations at nearby facilities (concrete, asphalt, and mechanical plants).
- Scenario 2: PM_{10} emissions from construction activities in Section 2, involving the same types of sources as in Section 1.
- Scenario 3: Represents $PM_{2.5}$ emissions during the construction of Section 1, including emissions from blasting, material handling in quarries, and operations at associated facilities such as concrete, asphalt, and mechanical plants located along this section.
- Scenario 4: Represents $PM_{2.5}$ emissions during the construction of Section 2, with the same emission sources as Scenario 3 blasting, quarry activities, and operations in nearby supporting facilities.
- Scenario 11: PM_{10} emissions arising solely from controlled blasting activities in Section 1 of the project area were assessed. To account for spatial and meteorological variability, seven distinct blasting scenarios were simulated within this section. The highest ground-level concentration observed across all simulations was selected to represent the worst-case condition for impact assessment.
- Scenario 12: This scenario evaluates PM_{10} emissions resulting exclusively from controlled blasting activities in Section 2 of the project area. As in Section 1, seven different blasting configurations were modeled. The maximum ground-level concentration from these simulations was used in the impact assessment to ensure a conservative evaluation of potential air quality impacts.
- Scenario 13: NO_2 emissions from construction machinery operating along Section 1 during the construction phase.
- Scenario 14: CO emissions from construction machinery operating along Section 1 during the construction phase.
- Scenario 15: NO_2 emissions from construction machinery operating along Section 2 during the construction phase.
- Scenario 16: CO emissions from construction machinery operating along Section 2 during the construction phase.
- Scenario 17: Settled dust emissions generated during the construction phase of the section1, including emissions from blasting activities, material handling in quarries, and operations in other related facilities (e.g., concrete, asphalt, and mechanical plants) located along this section.
- Scenario 18: Settled dust emissions generated during the construction phase of the section2, including emissions from blasting activities, material handling in quarries, and operations in other related facilities (e.g., concrete, asphalt, and mechanical plants) located along this section.

Operation Phase:

- Scenario 5: NO_2 emissions from traffic in Section 1.

Meteorological Parameters

AERMOD utilizes a meteorological data preprocessor AERMET. Hourly surface and upper air meteorological data inputs are processed by AERMET which generated SFC and PFL extended files for AERMOD. First, number of wind blows recorded in Manavgat Meteorological Station (Station Number: 17954) last 10 (ten) years (2015-2024) were compared with the average of the wind blow numbers recorded between 1960-2024 and the representative year was determined as 2022. Wind direction distribution analysis for 1960–2024, last 10 (ten) years, and 2022 are presented in Figure X.1

Following the determination of the representative meteorological year, hourly meteorological data and upper air observations were obtained from the meteorological stations best representing the project area. For this purpose, hourly surface data including humidity, pressure, temperature, precipitation, wind speed and direction were obtained from the Manavgat Meteorological Station (Station No: 17954). However, since cloud cover data were not available from this station, cloud cover and cloud ceiling height data were obtained from the nearest alternative station, the Alanya Meteorological Station (Station No: 17130). Upper air data were sourced from the Isparta Regional Meteorological Station (Station No: 17120). The collected data were processed using AERMET to generate the SFC and PFL files, which were subsequently used in AERMOD. According to the wind rose analysis presented in Figure X.1, the prevailing wind direction in the project area is the northern sector (N, NNW, NW, NNE). Winds from these directions occur with considerably higher frequency compared to other directions. In contrast, winds from the southern and western sectors are recorded at relatively lower frequencies. The wind speed distributions indicate that winds from the northern sector are predominantly concentrated within the medium to high-speed ranges.

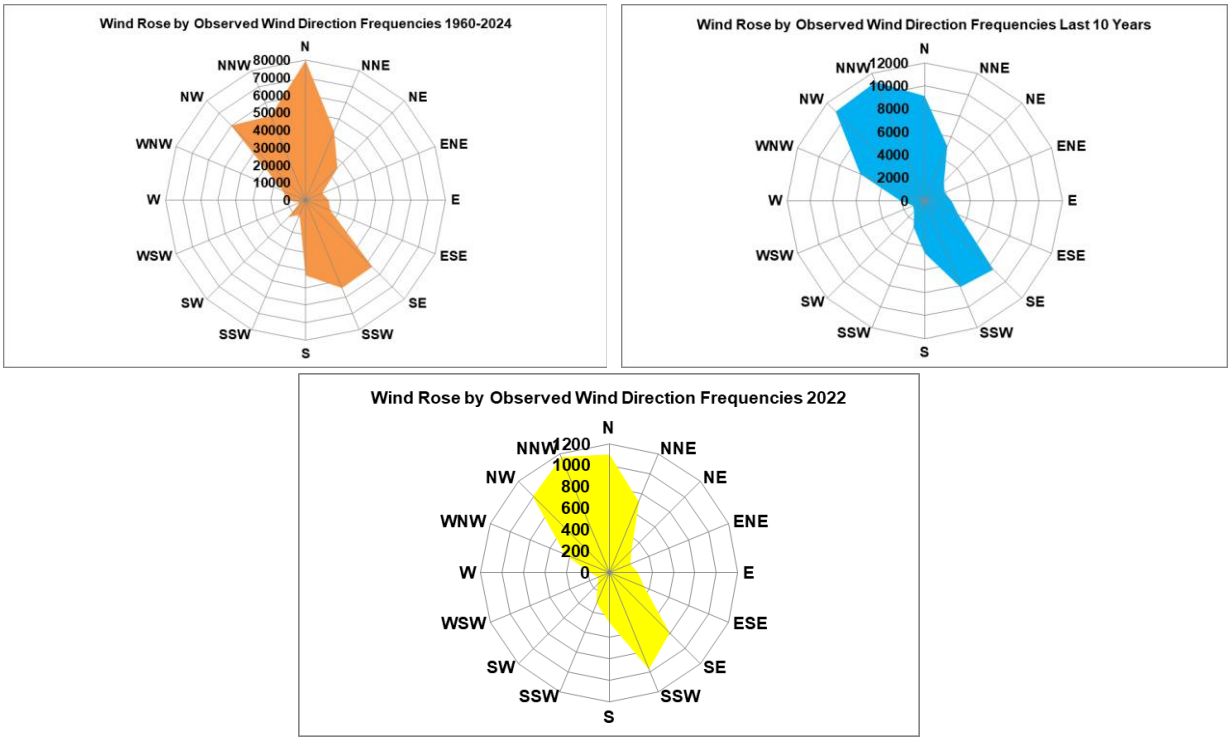

Figure X.1 Wind Direction Distribution Analysis for 1960–2024, Last 10 (ten) Years, and 2022

X.1.2. Baseline Conditions

Air quality measurements in Antalya province are performed regularly in air quality measurement station located in various point throughout the city. This station works under automatic data recording system, and the records are transferred to the National Air Quality Monitoring Network of Republic of Türkiye Ministry of Environment, Urbanization and Climate Change (MoEUCC). Air Quality Measurement Station representative for the Project in the province was selected and the measurement results for 2025 are presented in Table X.6.

Table X.6 Results of Air Quality Measurements in Antalya Province (2025)

Station Location	Distance to Project Route (km)	Parameters and Annual Measurement Results (µg/m^3)				
Antalya		**PM_{10}**	**SO_2**	**CO**	**NO_2**	**NO_x**
Serik	1.0	13.00	8.00	444.00	29.00	-
Manavgat	6.0	27.00	4.00	-	39.00	-
Alanya	8.0	26.00	-	-	11.00	-

Source: Republic of Türkiye, Ministry of Environment, Urbanization and Climate Change
https://sim.csb.gov.tr/Services/AirQuality

According to the limit values defined in the Regulation on Assessment and Management of Air Quality and Industrial Air Pollution Control Regulation, results for 2025 do not exceed the limit values at the station.

As part of the ESIA studies, air quality baseline measurements were conducted during the first week of September 2024 to determine the air quality along the Motorway route and its surrounding environment. These measurements included $PM_{2.5}$, PM_{10}, heavy metals in settled dust, settled dust, SO_2, NO_2 and VOC parameters, and were conducted at multiple locations. The selection of air quality measurement points prioritized sensitive areas such as settlements, quarries and areas with heavy urban traffic. Maps showing the air quality measurement locations are provided in Figure X.2. Laboratory reports are presented in Annex-2. Proximity of Residential and Sensitive Areas to the Project Route and its assessment is shown on Table X.7.

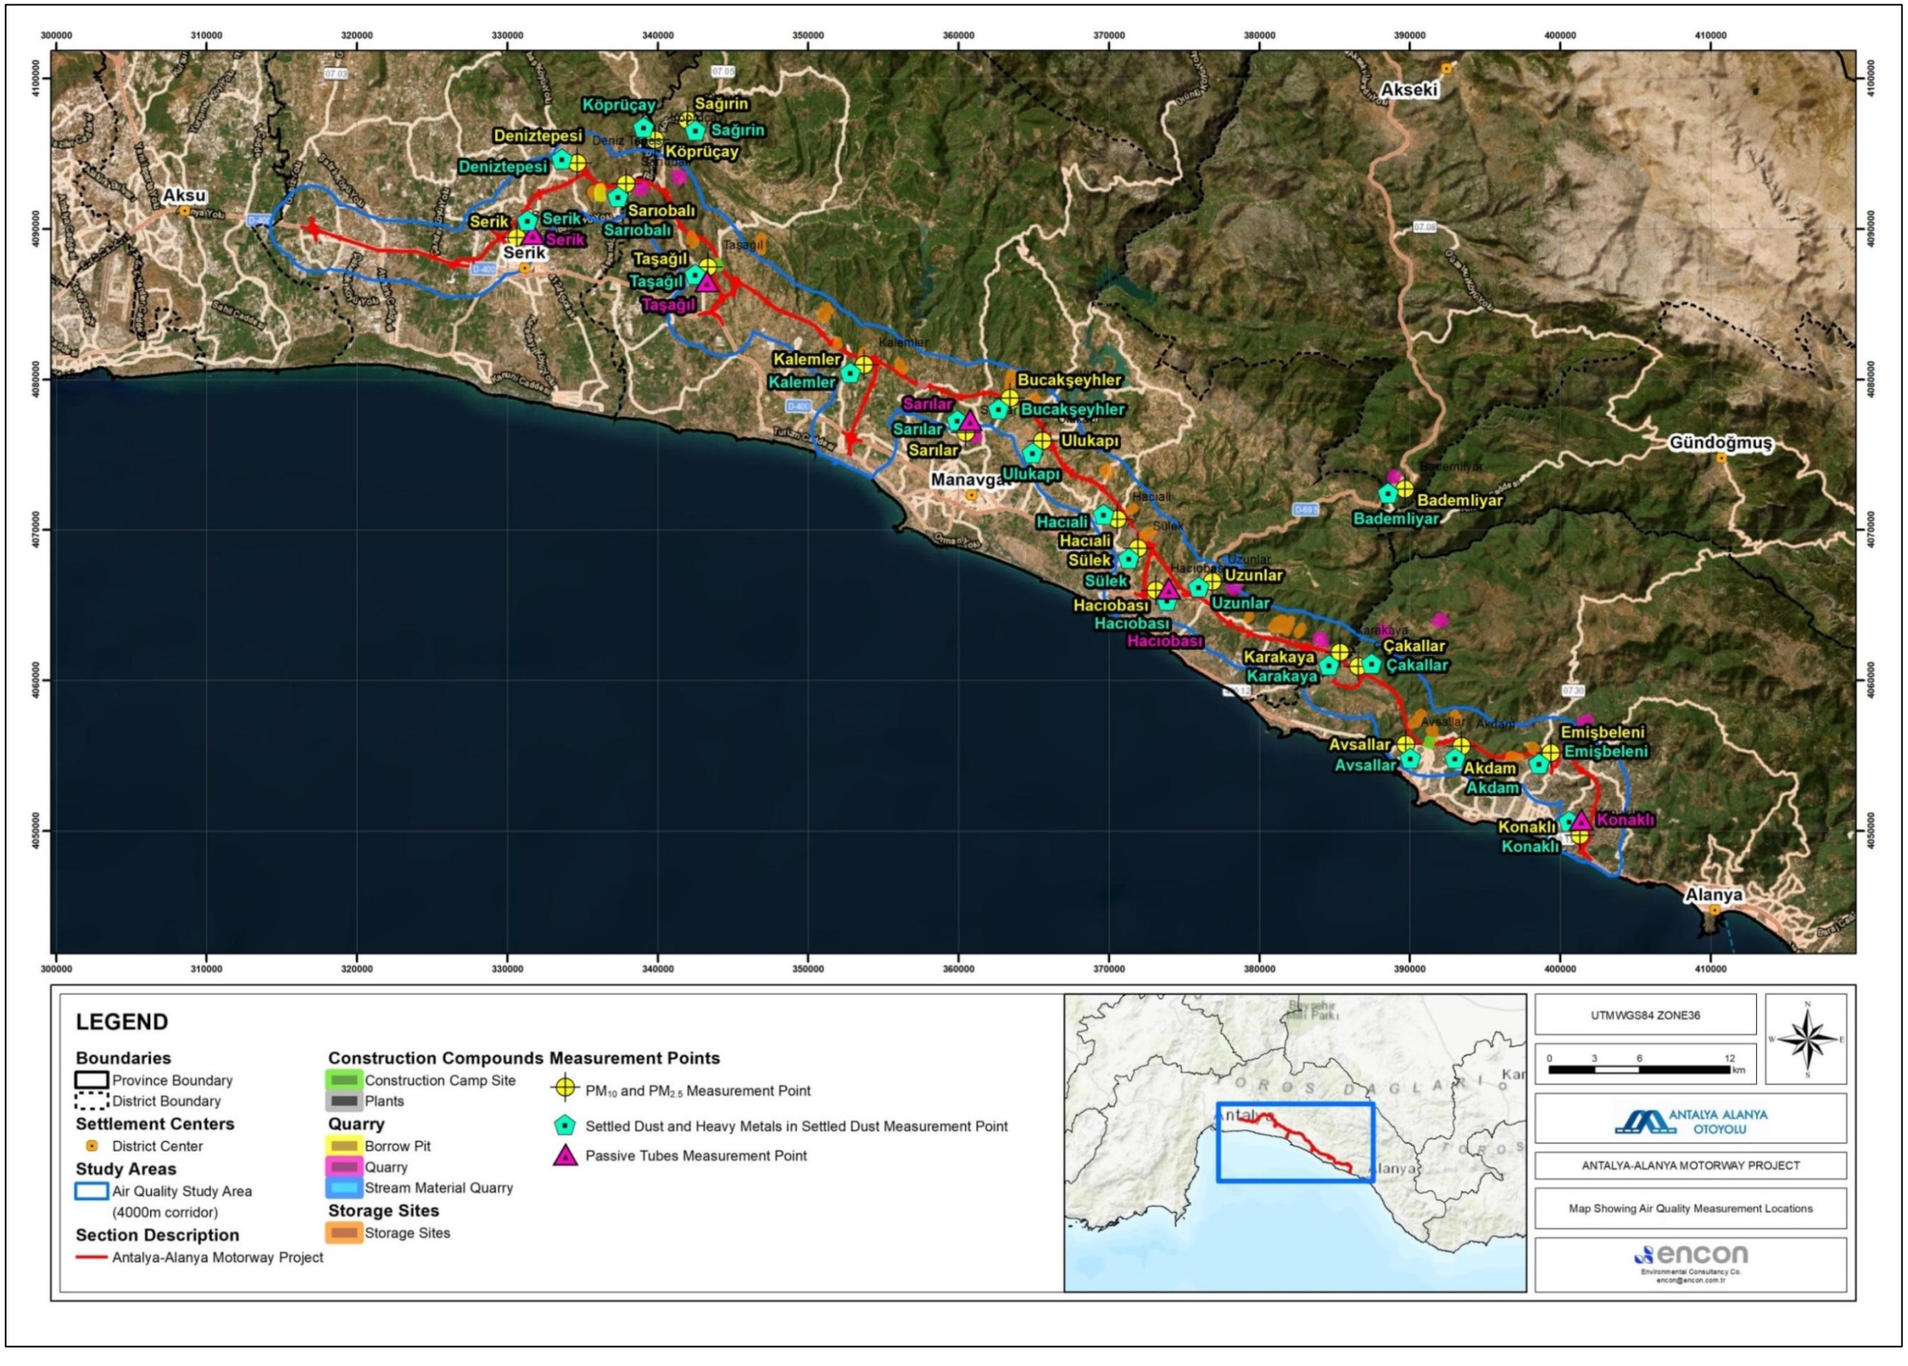

Figure X.2 Map Showing Air Quality Measurement Locations

Ambient air quality measurements were conducted at 21 locations during September–October 2024. The campaign covered PM_{10}, $PM_{2.5}$, settled dust, and heavy metals in settled dust. PM measurements were taken over 24-hour periods at each location, consistent with IFC's Environmental, Health and Safety (EHS) Guidelines for Air Emissions and Ambient Air Quality, which recommend 24-hour averaging periods for particulate matter to ensure comparability with WHO and national standards.

Although PM_{10} and $PM_{2.5}$ data were collected on a single day at each location, the following factors support the adequacy and representativeness of this approach in the context of IFC PS3:

- The monitoring campaign was conducted under normal operational conditions with no exceptional emission sources (e.g., construction works, or accidental releases) observed during the measurement days. Local activities and emission sources were stable and typical for the season.
- Weather conditions during the campaign (e.g., wind speed and direction, temperature, humidity) reflected seasonal averages and did not include any meteorological extremes. This ensured that dispersion conditions were typical and data were not biased by anomalies such as inversions or dust storms.
- The 21 sampling points were carefully selected to capture spatial variability, including background areas, residential zones, roadside locations, and areas near potential emission sources. This wide coverage compensates for the temporal limitation and provides a robust spatial profile of ambient air quality across the project area.
- Short-term baseline assessments with targeted 24-hour sampling campaigns are recognized under the IFC EHS Guidelines as appropriate for infrastructure projects, particularly where long-term seasonal variation is not a dominant factor.

In summary, the design and implementation of the air quality baseline campaign conform to IFC Performance Standard 3 and associated technical guidelines. The collected data are representative of typical ambient conditions and sufficient to assess potential impacts and inform mitigation strategies for the expressway project.

Measurements were conducted at 21 different points. Settled dust was measured over a 2-month period, while PM_{10} and $PM_{2.5}$ were measured over 24-hour periods. The results are presented in Table X.8.

Table X.8 Results of PM_{10}, $PM_{2.5}$,Settled Dust and Heavy Metals in Settled Dust Measurements (September- October 2024)

Turkish Air Quality Standards[1]			**50.0**	**210.0**	**-**			
IFC Air Quality Standards[2]			**50.0**		**25**		**-**	
European Directives[3]			**50.0**		**25**		**-**	

[1] Regulation on Control of Industrial Air Pollution (Dated 03.07.2009 and Numbered 27277) and Regulation on Assessment and Management of Air Quality (Dated 06.06.2008 and Numbered 26898)
[2] IFC General Environmental, Health, and Safety (EHS) Guidelines (WHO stands for World Health Organization) (Dated 30 April 2007)
[3] Directive 2008/50/EC, 21 May 2008, ambient air quality

As seen above, all results comply with the Air Quality Assessment and Management Regulation, the Regulation on the Control of Industrial Air Pollution, IFC standards and EU Regulations; however, the PM_{10} value at Hacıali should be monitored closely, as it is near the daily limit value 50 µg/m³. The potential contributing factors to this elevated PM_{10} concentration include the high traffic density in the Hacıali neighborhood.

Heavy metal concentrations in settled dust (Cadmium, Lead, and Thallium) were found to be below detection limits in all sampled neighborhoods. Although certain limit values related to settled dust and ambient air quality are defined in Turkish regulations (Table X.1) and EU directives (Table X.3), the results indicate that there is no significant pollution. These findings are consistent with the general principles of the Regulation on Air Quality Assessment and Management, the Regulation on the Control of Industrial Air Pollution, and relevant EU air quality directives.

Since no specific limit values are defined under the EU or IFC standards for settled dust, the measurement results have been evaluated in accordance with the limit values set by the Regulation on Air Quality Assessment and Management and the Regulation on the Control of Industrial Air Pollution. The results were found to be below the applicable limits defined in these national regulations.

The measurement results are below the limit values defined in the IFC standards (24-hour limit value), except for the Hacıali neighborhood, where the $PM_{2.5}$ concentration appears to be higher than the regulatory limit values. This can be explained by the high traffic load in Hacıali neighborhood and their immediate surroundings.

SO_2 and NO_2 were monitored using passive sampling over a one-month period between September 21 and October 21, 2024, at the five selected locations. VOC measurements were conducted on October 17, 2024.

Baseline monitoring for PM_{10}, $PM_{2.5}$, and settled dust was conducted at 21 locations to capture local variability influenced by site-specific conditions such as surface activities, unpaved roads, and nearby construction or traffic.

In contrast, gaseous pollutants such as SO_2, NO_2, and VOCs were measured at five representative locations. This decision was based on the following technical and methodological considerations:

- Unlike particulate matter, which exhibits significant micro-scale variation due to local dust-generating activities, gaseous pollutants tend to have broader dispersion characteristics. Pollutants like NO_2 and SO_2 are emitted primarily from combustion sources (e.g., vehicles), and their ambient concentrations over regional scales are relatively stable and homogeneous—especially in the absence of strong point sources. Therefore, a smaller number of well-distributed sampling points is sufficient to characterize background levels and inform modeling inputs.
- The five selected locations—Hacıobası, Konaklı, Sarılar, Serik, and Taşağıl—were chosen to represent a cross-section of relevant environmental settings, including residential areas, proximity to the highway alignment, agricultural zones, and receptor-sensitive areas. This ensures that spatial diversity is adequately captured despite the smaller sample size.
- SO_2 and NO_2 were measured using passive diffusion tubes deployed over a one-month period. This method, while highly effective for capturing average ambient concentrations, requires manual installation and retrieval, as well as laboratory analysis. As per best practice and IFC-aligned methodologies, passive sampling is typically conducted at fewer, but more representative locations to balance cost, feasibility, and data quality.

- VOC sampling requires active sampling equipment and laboratory coordination, which is often focused on areas with potential human exposure or suspected hydrocarbon emissions. In this context, the selected five locations provide sufficient spatial coverage given the anticipated low emission profile of VOCs in the area.
- IFC's Air Emissions and Ambient Air Quality guidance recognizes that the extent of monitoring should be proportional to the project's potential for emissions and environmental risk. In the absence of significant industrial sources or dense urban activity, the chosen five-site gaseous monitoring network is deemed proportionate, representative, and sufficient for baseline characterization.

Table X.9 Results of Passive Measurements

Neighbourhood	Corresponding Motorway (KM)	UTM WGS84 ZONE 36 Coordinates	VOCs (µg/m³)	SO_2 (µg/m³)	NO_2 (µg/m³)
Hacıobası	Manavgat East Access Road 1+000	373104/4065985	2.0	<10.27	<4.24
Konaklı	140+600	401287/4049717	2.0	<10.27	<4.24
Sarılar	83+500	360448/4076493	1.0	24.21	<4.24
Serik	Serik Access Road 7+000	330608/4089427	1.0	<10.27	<4.24
Taşağıl	Taşağıl Access Road 2+500	343326/4087476	1.0	<10.27	<4.24
Turkish Air Quality Standards			**70**	**125.0**	**200.0**
IFC Air Quality Standards			**-**	**20.0**	**40.0**
European Directives			**70**	**125.0**	**40.0**

The results, presented in Table X.9, generally remained below the limit values set by the EU Directives, the Regulation on Air Quality Assessment and Management, and the Regulation on the Control of Industrial Air Pollution. However, some SO_2 concentrations measured in the Sarılar neighborhood exceeded the IFC guideline value of 20 µg/m³, despite remaining below the IFC Interim Targets of 125 µg/m³ (Target 1) and 50 µg/m³ (Target 2). This exceedance is considered to be related to the presence of greenhouse and residential areas in close proximity to roads open to vehicular traffic.

X.1.3. Potential Impacts

Emissions during construction phase of the Project will consist of $PM_{2.5}$, PM_{10}, heavy metals in settled dust, settled dust, SO_2, NO_2, VOCs from construction machinery and equipment. During the operation phase of the Motorway, similar to the other combustion processes, emissions from vehicles include CO, NOx, SO2, PM and VOCs[4]. Within this context, main air pollutants of concern regarding the Project are described below:

Particulate Matter (PM)

PM stands for particulate matter (also called particle pollution): the term for a mixture of solid particles and liquid droplets found in the air. Some particles, such as dust, dirt, soot, or smoke, are large or dark enough to be seen. Others can only be detected using an electron microscope. Particulate matter

[4] IFC General Health and Safety Guidelines on Air Emissions and Ambient Air Quality

includes PM_{10} inhalable particles, with diameters that are generally 10 micrometers and smaller; and $PM_{2.5}$; fine inhalable particles, with diameters that are generally 2.5 micrometers and smaller[5].

Particulate matter come in many sizes and shapes and can be made up of hundreds of different chemicals. Some are emitted directly from a source, such as construction sites, unpaved roads, fields, smokestacks or fires. Most particles form in the atmosphere as a result of complex reactions of other pollutants such as sulfur dioxide and nitrogen oxides.

Once inhaled, these particles can affect the heart and lungs and cause serious health effects. Particles less than 10 micrometers in diameter pose the greatest problems, because they can get deep into lungs, and some may even get into the bloodstream.

Particles can vary according to size and composition. PM_{10} (particulate matter with aerodynamic diameter smaller than 10 μm) standard is set to define the particles that people are likely to inhale and PM_{10} has become the general measure of particulate matter.

Settled Dust

Settled dust consists of airborne particles that settle onto the ground or other surfaces due to gravity. These particles can originate from construction activities, quarries, excavation, road works, and other land preparation operations. Settled dust varies in size and composition and may contain heavy metals or other pollutants. From a health perspective, the inhalable fraction of dust (especially PM10 and PM2.5) can cause respiratory problems and affect lung and heart function. Environmentally, settled dust can accumulate on plants, water bodies, and cultural structures, potentially causing adverse effects.

Carbon monoxide (CO)

Carbon monoxide (CO) is a colorless, odorless gas that can be harmful when inhaled in large amounts. It is formed both naturally and human activities such as in complete burning of fossil fuels, and it is important to note that natural processes produce relatively small amounts of CO when compared to anthropogenic sources. Main sources of CO in outdoor air can be accepted as cars, trucks and other vehicles and machinery that burn fossil fuels. Therefore, it can be said that CO levels in urban areas is closely related with traffic density. Other anthropogenic sources of the pollutant are power stations and waste incinerators.

Human inhalation of air with high CO concentration is known to reduce the amount of oxygen carrying capacity of blood stream as CO is rapidly absorbed by blood. Very high levels are generally associated with indoor pollution however; significant health problems for vulnerable individuals can be observed when CO levels are elevated outdoors.

CO is considered as a relatively stable compound and takes part slowly in atmospheric chemical reactions. CO reacts with other pollutants in air to form ozone. This forms ground level ozone which does not have significant environmental impacts at a global level. On the other hand, CO contributes indirectly to greenhouse effect by depleting hydroxyl radicals and slowing destruction of methane.

Sulfur Dioxide (SO_2)

Sulfur Dioxide (SO_2) is one of a group of gases called sulfur oxides (SO_x). While all of these gases are harmful to human health and the environment, (SO_2) is of greater concern. Other gaseous SO_x (such as SO_3) are found in the atmosphere at concentrations much lower than (SO_2). The largest sources of

[5] https://www.epa.gov/pm-pollution

(SO_2) emissions are from fossil fuel combustion at power plants and other industrial facilities. Smaller sources of (SO_2) emissions include: industrial processes such as extracting metal from ore; natural sources such as volcanoes; and transportation via locomotives, ships and other vehicles and heavy equipment that burn fuel with high sulfur content.

SO_2 can affect both health and the environment. Short-term exposures to SO_2 can harm the human respiratory system and make breathing difficult. Children, the elderly, and those who suffer from asthma are particularly sensitive to effects of SO_2.

SO_2 emissions that lead to high concentrations of pollutants in the air generally also lead to the formation of other sulfur oxides (SO_x). SO_x can react with other compounds in the atmosphere to form small particles. These particles contribute to particulate matter (PM) pollution: and cause additional health problems and reduce visibility (haze). Deposition of particles can also damage stone and other materials, including culturally important objects. In addition, at high concentrations, gaseous SO_x can harm trees and plants by damaging foliage and decreasing growth. SO_2 and other sulfur oxides can contribute to acid rain which can harm sensitive ecosystems *(https://www.epa.gov/so2-pollution).*

Nitrogen Dioxide (NO_2)

Nitrogen Dioxide (NO_2) is one of a group of highly reactive gases called nitrogen oxides (NO_x). While all of these gases are harmful to human health and the environment, NO_2 is of greater concern. Other nitrogen oxides include nitrous acid and nitric acid. NO_2 primarily gets in the air from the burning of fuel. NO_2 forms from emissions from cars, trucks and buses, power plants, and off-road equipment.

Breathing air with a high concentration of NO_2 can irritate airways in respiratory system. Such exposures over short periods can cause respiratory diseases such as asthma, leading to respiratory symptoms such as coughing, or difficulty in breathing. Longer exposures to elevated concentrations of NO_2 may contribute to the development of serious health problems. NO_2 reacts with other chemicals in the air to form both particulate matter and ozone. Both of these are also harmful when inhaled due to effects on the respiratory system *(https://www.epa.gov/no2-pollution).*

NO_2 and other NO_x interact with water, oxygen and other chemicals in the atmosphere to form acid rain. Acid rain harms sensitive ecosystems such as lakes and forests. The nitrate particles that result from NO_x make the air hazy and decrease visibility. In addition, NO_x in the atmosphere contributes to nutrient pollution in coastal waters.

Volatile Organic Compounds (VOCs)

VOCs are organic compounds containing one or more carbon atoms that have high vapor pressures and therefore evaporate readily to the atmosphere. There are thousands of compounds that meet this definition. VOCs play a significant role in the formation of ozone and fine particulates in the atmosphere. Under sunlight, VOCs react with nitrogen oxides emitted mainly from vehicles, power plants and industrial activities to form ozone, which in turn helps the formation of fine particulates. The accumulation of ozone, fine particulates and other gaseous pollutants results in smog that reduces visibility. Smog is particularly severe under stagnant weather conditions.
Smog can irritate eyes, nose and throat, or can worsen existing heart and respiratory problems such as asthma. People with heart and lung problems, the elderly and children whose respiratory systems are still developing are most at risk. Prolonged exposure to severe smog condition may cause

permanent damage to lung tissue and affects the human immune system. In addition, smog impairs visibility[6].

Abovementioned pollutants are expected to be emitted during land preparation, construction and operation phases of the motorway project. In order to determine the potential impacts of project emissions on air quality, the sources of pollutants are clearly defined and amounts of pollutants emitted from each source are quantified. Sources and amounts of project emissions are described in detail for land preparation and construction and operation phases of the Project separately in the following parts.

X.1.3.1. Land Preparation and Construction Phase

Construction phase activities are expected to result in dust emissions during land preparation, cut-fill operations and activities of quarries operated in the scope of the Project. In addition, exhaust emissions such as PM_{10}, $PM_{2.5}$, settled dust, NO_x, CO, SO_2, VOC, benzene, NH_3 and N_2O are also expected. Asphalt plants and concrete plants are considered as other emission sources of construction activities. Campsites, concrete plants, asphalt plants, mechanical plants, quarries, material storage sites/borrow pits to be operated during the construction phase are presented in Figure X.3.

[6] *http://www.epd.gov.hk/epd/english/environmentinhk/air/prob_solutions/vocs_smog.html*

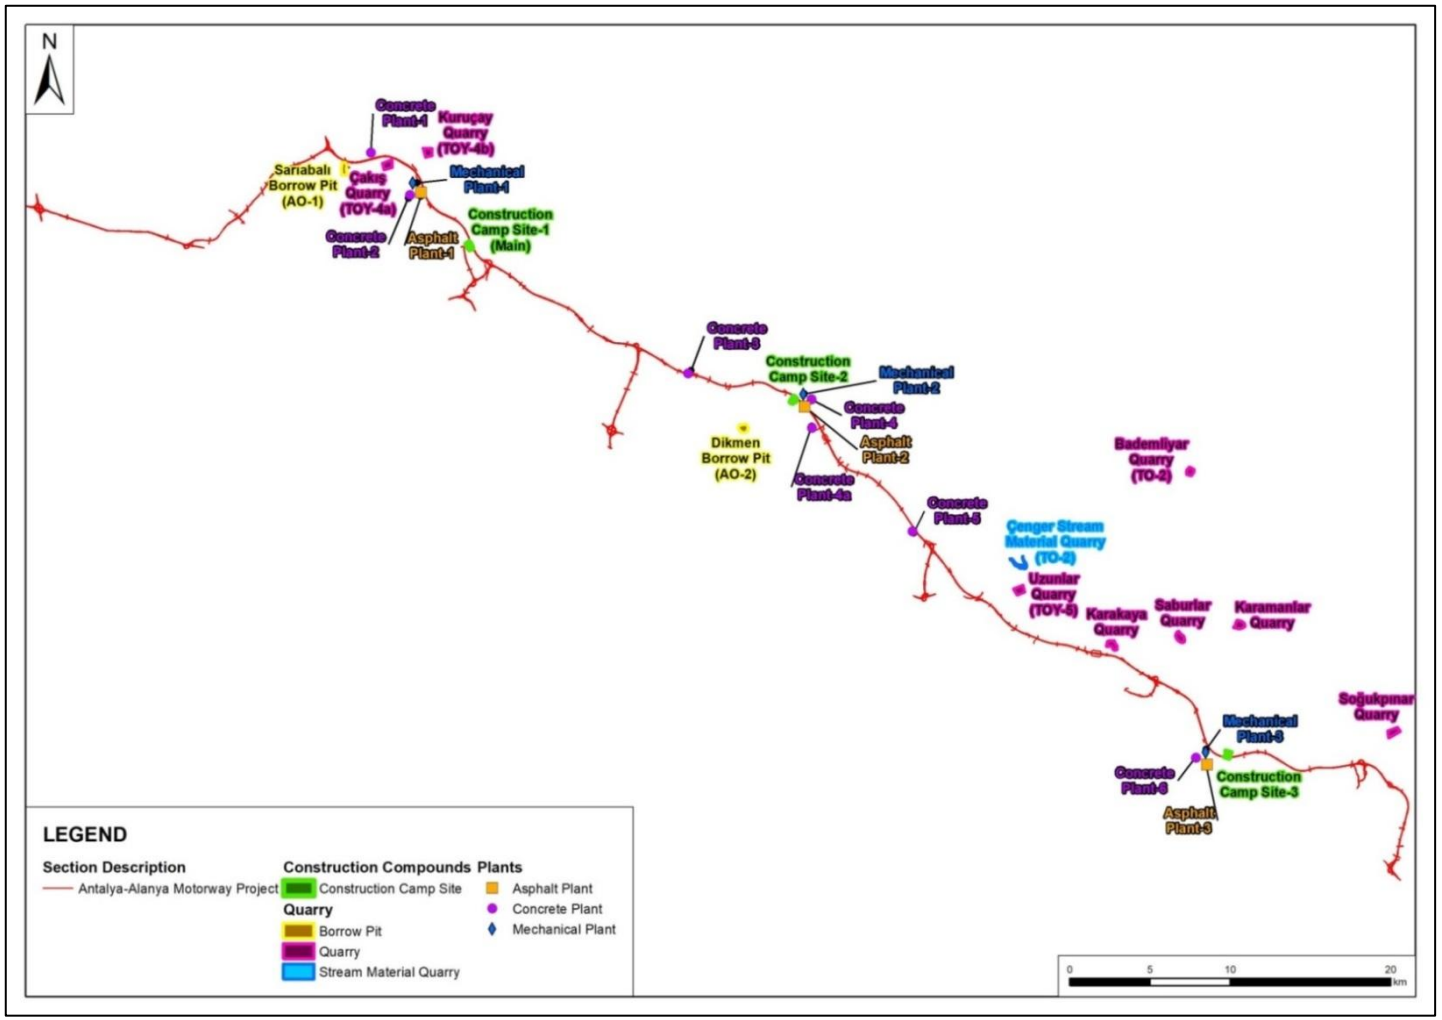

Figure X.3 Related Project Components to be Utilized during Construction Phase of the Project

According to the Project schedule, it is planned that the construction works will last at most three years. Within this scope, top-soil stripping will be followed by excavation, fill and leveling. Next, bridges, underpass and overpass bridges, culverts and viaducts, will be established accordingly.

Modeling studies were carried out for NO_2, VOC, CO and SO_2 parameters, and each pollutant under 2 different scenarios (Section 1, Section 2) and the possible effects of pollutant sources on local air quality were examined in accordance with each scenario.

Section 1 corresponds to the segment between kilometers Km: 52+000 and Km: 97+000 of the planned motorway, while Section 2 covers the segment between kilometers Km: 97+000 and Km: 142+000. Excavation (cut) and fill (embankment) amounts for Section 1 and Section 2 are presented in Chapter VII.

In the scope of road construction works, excavated materials are planned to be used in the fill operations wherever the properties and the quality of the materials are suitable. When there is a surplus of excavated materials, excess material will need to be stored at designated storage areas. If there is a need for supply of construction material, it will be supplied from nearby licensed quarries to the extent possible.

Materials will be sourced from ten different quarries, mines, and facilities. Material extracted from the quarries will be transferred to crushers located nearby. According to the KGM Technical Specifications, crushers shall operate in enclosed areas and be equipped with dust suppression systems. Excess material from excavation will be stored in designated storage areas. Detailed information on the quarries, storage areas, and facilities is provided in Annex 6.
Emission factors defined in Industrial Air Pollution Control Regulation will be used to calculate the dust emissions from excavation and fill operations. These emission factors are presented in Table X.10. Uncontrolled emission factors represent the case in which the activities are performed without any measures taken, while controlled emission factors represent the case when measures such as watering, usage of closed transportation systems, keeping the material moisturized and performing loading and unloading of materials without scattering are taken. A detailed breakdown of dust emissions related to the Project is provided in Annex 6 of the Air Quality Modeling Report.

Table X.10. Emission Factors for Dust Emissions

Sources	Emission Factors		Unit
	Uncontrolled	Controlled	
Excavation	0.025	0.0125	kg/ton
Loading	0.010	0.005	
Unloading	0.010	0.005	
Primary Crusher	0.243	0.0243	
Secondary Crusher	0.585	0.0585	
Tertiary Crusher	0.585	0.0585	
Transportation (round-trip total distance)	0.7	0.35	kg/km-vehicle
Storage	5.8	2.9	kg dust/ha.day

Source: Industrial Air Pollution Control Regulation, Annex-12

Air Quality Modeling for Land Preparation and Construction Phase

Dust emissions are expected during construction activities within the Project Area. Emissions for the facility's operation phase have been estimated using emission factors from the Emission Estimation Technique Manual for Mining, published by the Australian Government Department of the Environment. These factors are primarily based on the U.S. EPA's AP-42 – Compilation of Air Pollutant Emission Factors. Although the project is located in Türkiye, it is common practice in environmental impact assessments conducted there to utilize internationally recognized emission factors—especially when local factors are either too generalized or do not adequately reflect the specific types of activities involved. In this context, Australian emission factors were selected due to their relevance to construction-related operations and their alignment with widely accepted international modeling standards. The emission factors used in the calculations are detailed in Table X.11.

This study covers emission estimates from excavation and filling works related to road construction, as well as emissions from quarries, concrete batching plants, mechanical plants, and asphalt plants planned along the project route. These sources represent material extraction, processing, and handling activities during both construction and operation phases. Details on the locations, types, and operation capacities of the facilities included in the modeling are provided in **Error! Reference source not found.**.

In this study, motorway construction emissions were calculated based on the year 2026, during which the highest material production volumes were scheduled according to the construction plan. A daily working duration of 20 hours was assumed to represent two active shifts, and this assumption was directly applied in the estimation of hourly emissions.

For detailed calculations of the emissions caused by each emission source mentioned in this section, such as excavation and fill operations, storage areas, asphalt plants, construction machinery and equipment, refer to the Annex-6 Air Quality Modeling Report.

Table X.11 Default Emission Factors for Various Operations at Mines

Activity	PM_{10} Default Emission Factor	Unit
Excavators/Shovels/Front-end loaders (on overburden).	0.012	kg/t
Excavators/Shovels/ Front-end loaders (on coal).	0.014	kg/t
Scrapers (removing topsoil)	0.0073	kg/t
Material loading-unloading	0.0043	kg/t
Blasting	$0.00114 \times A^{1.5}$	kg/blast
Wheel generated dust from unpaved roads at industrial sites	1.25	kg/VKT
Wind Erosion	0.2	kg/ha/hour
Primary crusher	0.02	kg/t

A=blasting area,m^2

In order to assess the potential impacts of the Project's construction activities, air quality modeling studies were conducted for PM_{10}, $PM_{2.5}$, settled dust, NO_2, and CO parameters. The Air Quality

Modeling Report has been submitted as an annex to this report. As part of the modeling studies, daily and annual PM_{10} concentrations and $PM_{2.5}$ levels were determined and compared with the air quality limit values defined in the Regulation on the Assessment and Management of Air Quality, the Regulation on the Control of Industrial Air Pollution, EU directives, and IFC standards (see Table X.1, Table X.2, and Table X.3).

For each pollutant, modeling was carried out under a single scenario, and the potential effects of emission sources on local air quality were evaluated in accordance with this scenario.

PM_{10} Concentrations at Ground Level

According to the scenarios defined for the construction phase, the ground-level concentration (GLC) values of PM_{10} expected to occur around the existing facilities are presented in Table X.12. In addition, maximum daily and annual emission distribution maps for PM_{10} are provided in Figure X.4, through Figure X.11.

Table X.12 Results of ground-level PM_{10} concentrations observed in different scenarios

Scenario	PM_{10} Highest Daily ($\mu g/m^3$)	Number of Exceedances	PM_{10} Highest Annual ($\mu g/m^3$)	UTM WGS 84 ZONE 36 Coordinates (Daily / Annual)	Distance (m)	Direction (from Emission Source to GLC)
Scenario 1 Construction-Section1	413.31	30	20.56	Daily: (337884, 4093014) / Annual: (360491, 4077639)	25 / 1,200	Southeast / South
Scenario 2 Construction-Section2	968.81	33	23.2	Daily: (391106, 4054935) / Annual: (391106, 4054935)	770 / 770	South / South
Scenario 11 Blasting-Section1	456.72	17	5.64	Daily: (335487, 4092726) / Annual: (334987, 4094226)	530 / 60	Southwest / West
Scenario 12 Blasting-Section2	1614.84	17	11.49	Daily: (383419, 4061430) / Annual: (380419, 4063430)	555 / 625	Southeast / North
IAPCR Limit Values	**50**	**Max 35 exceedances/year**	**40**	**-**	**-**	**-**
IFC Standards	**50**	**-**	**20**	**-**	**-**	**-**
EU Directives	**50**	**Max 35 exceedances/year**	**40**	**-**	**-**	**-**

As presented in Table X.12, PM_{10} measurements indicate that daily concentrations exceed the IAPCR, IFC, and EU limits in certain scenarios. However, when considering the maximum number of exceedances allowed per year, all scenarios remain within the permissible limits. The term “Number of exceedances” refers to the maximum number of days in a year on which the 24-hour limit can be exceeded; that is, out of 365 days in a year, the 24-hour limit may be exceeded on a maximum of 35 days.

Scenario 1 (Construction-Section1): Daily PM_{10} concentrations exceed the 24-hour limits of IAPCR, IFC, and EU standards, while the annual averages remain below all regulatory thresholds. The number of exceedance days is within the annual maximum allowed. The elevated daily values are associated with construction activities and material handling in this section.

Scenario 2 (Construction-Section2): Similar to Scenario 1, daily PM_{10} concentrations surpass all regulatory limits, whereas annual concentrations remain below the IAPCR and EU limits but approach the IFC annual threshold. The daily exceedances remain within the permitted annual count. The higher values compared to Scenario 1 are linked to more intensive construction and traffic activities in this section.

Scenario 11 (Blasting-Section1): Daily PM_{10} values are above the 24-hour limits, while annual averages remain well within all regulatory limits. The lower daily exceedances compared to construction scenarios reflect the intermittent nature of blasting operations.

Scenario 12 (Blasting-Section2): This scenario shows the highest daily PM_{10} concentrations, exceeding all 24-hour limits. Although annual averages meet the IAPCR and EU thresholds, they slightly exceed the IFC annual limit. The daily exceedance count, however, is still within the allowed maximum. The elevated values are primarily due to blasting operations combined with material transport.

In areas with the highest pollutant concentrations, targeted mitigation measures, as detailed in Section X.1.4.1, will be implemented to reduce emissions and ensure compliance with applicable air quality standards. These measures aim to control dust generation from construction, blasting, and material handling activities, thereby protecting nearby sensitive receptors.

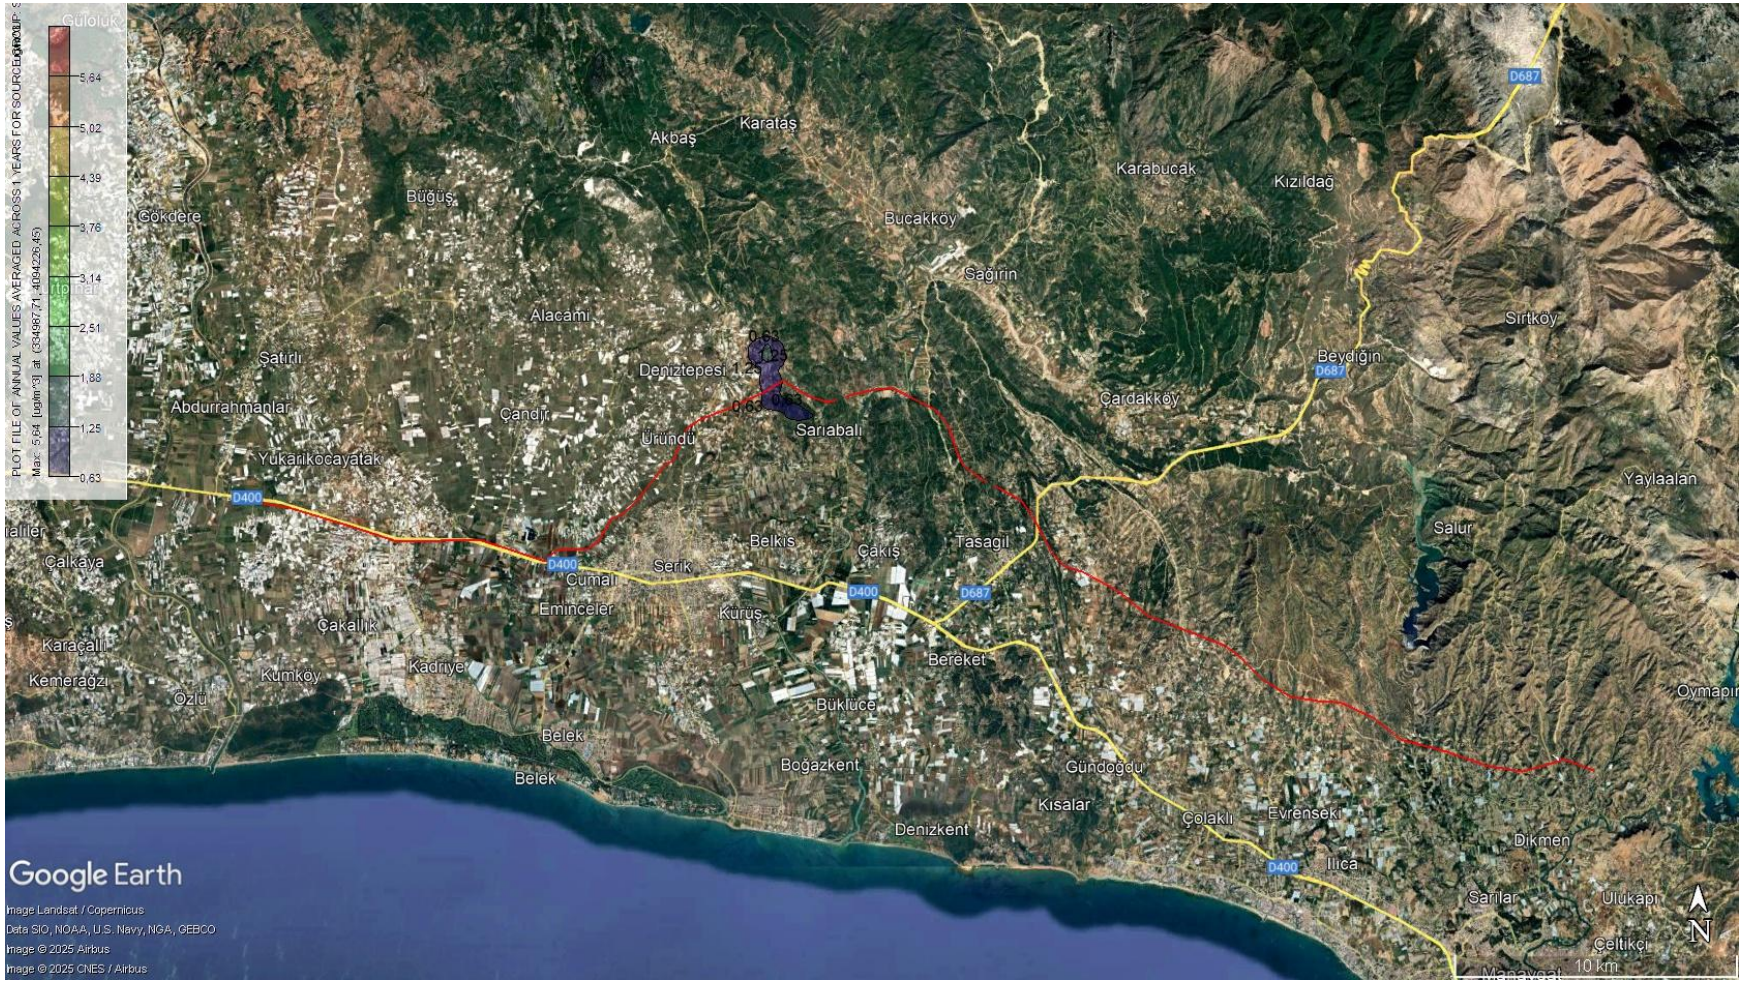

Figure X.9 Maximum annual PM_{10} emission distribution-Section1-Blasting (µg/m^3)

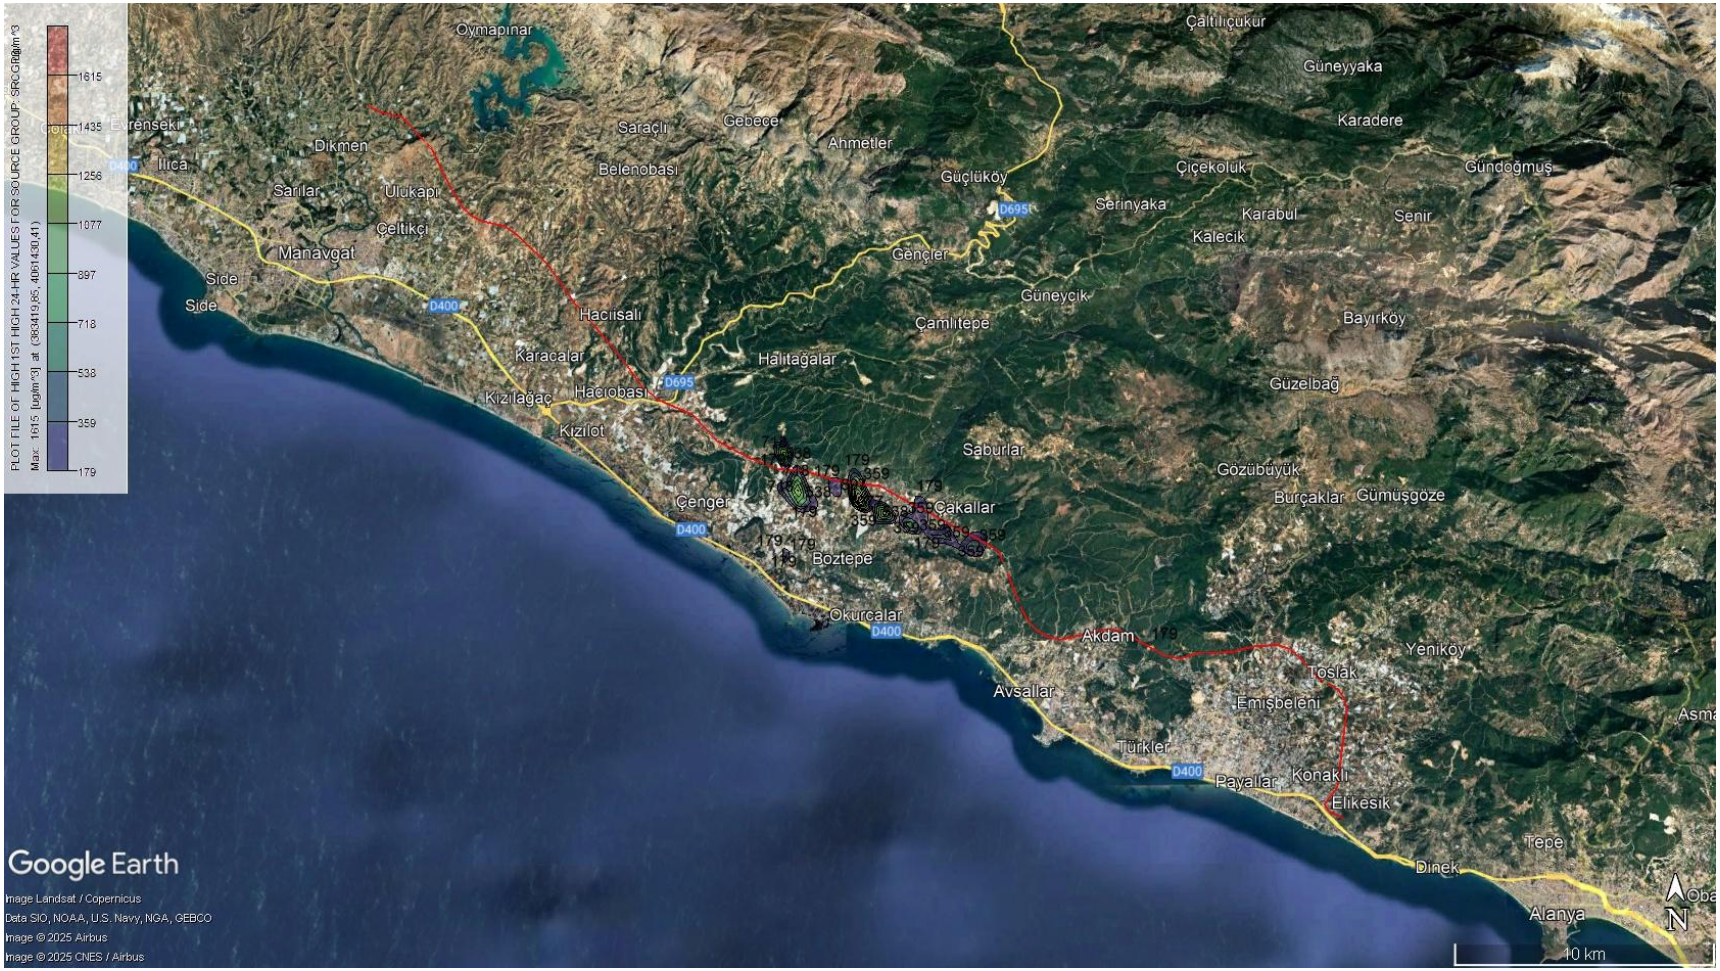

Figure X.10 Maximum daily PM10 emission distribution- Section2-Blasting (µg/m^3)

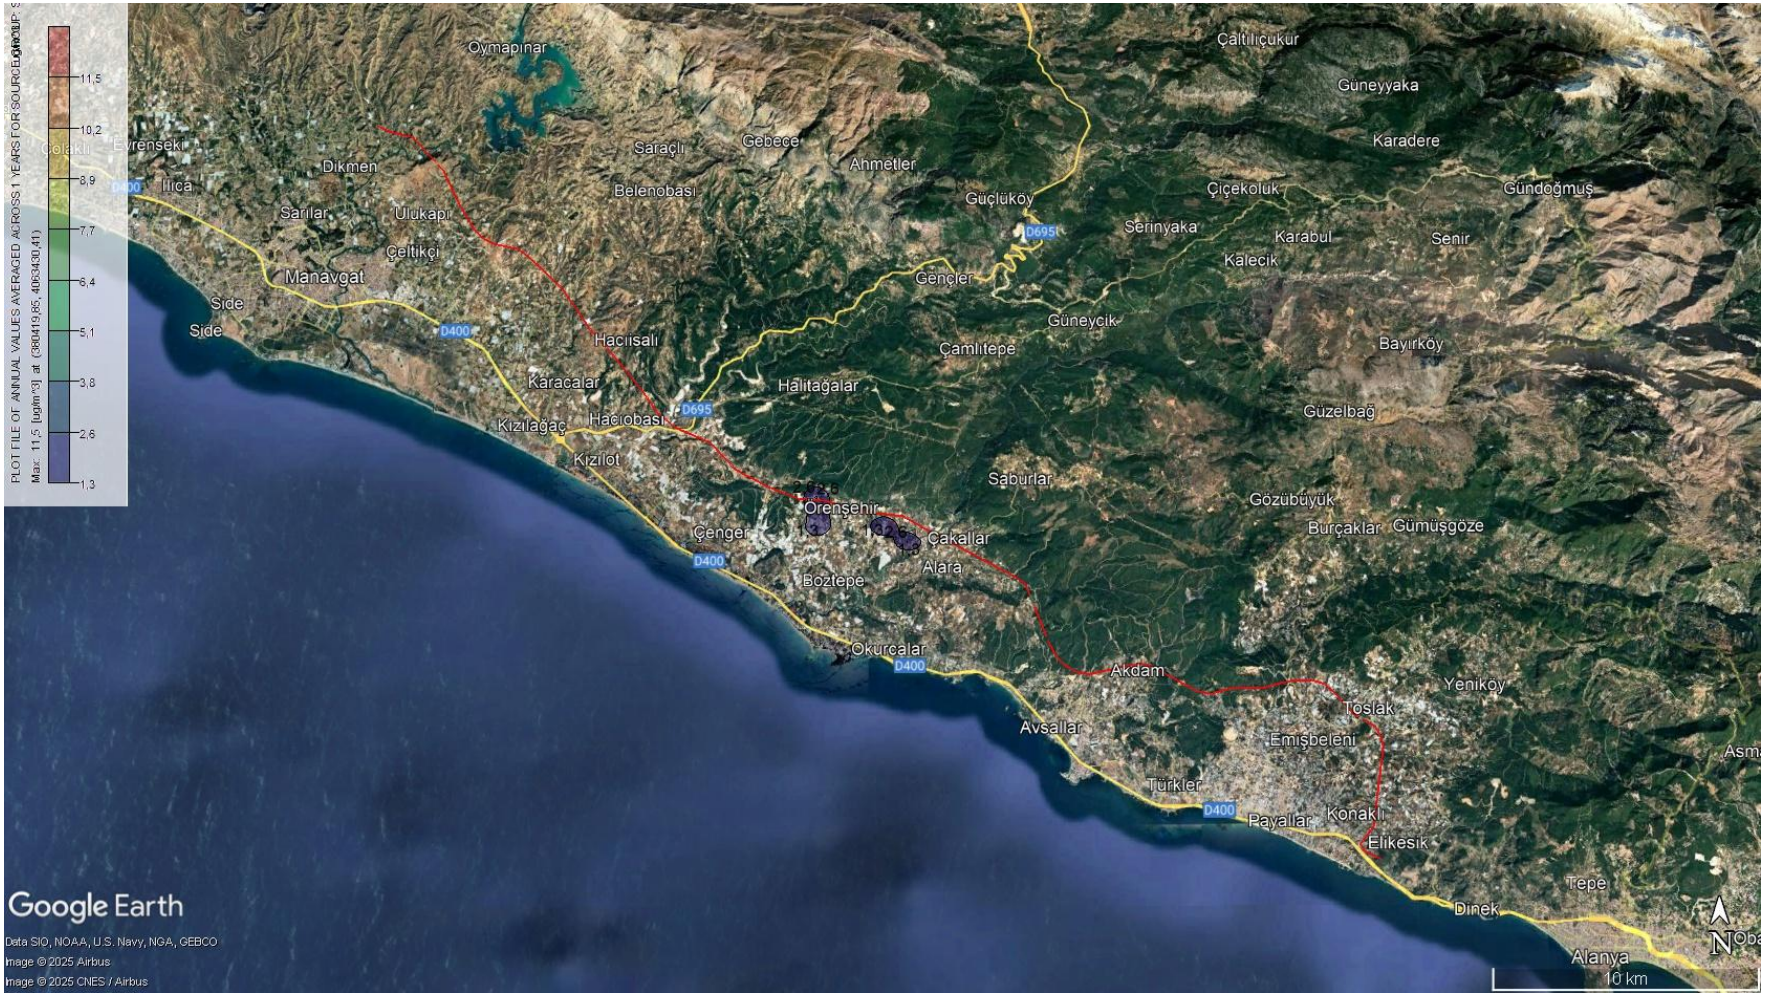

Figure X.11 Maximum annual PM_{10} emission distribution-Section2-Blasting (µg/m^3)

The study assessed cumulative PM_{10} concentrations by adding measured background values to the maximum daily modeled emissions at each location (see Table X.13). The highest concentration occurred in Sarıabalı at 429.81 µg/m³, with 413.31 µg/m³ originating from project activities. Despite this, the site remained compliant with regulatory exceedance limits (33 days/year).

Other key locations also stayed within allowable limits:

- Akdam: 266.49 µg/m³, 19 exceedances – compliant
- Karakaya: 185.64 µg/m³, 11 exceedances – compliant
- Köprüçay: 111.38 µg/m³, 26 exceedances – compliant
- Ulukapı: 58.10 µg/m³, 3 exceedances – compliant

Serik, Sülek, and Deniz Tepesi recorded low cumulative values and no significant exceedances.

However, Hacıali stands out with 248 exceedance days/year, far exceeding legal thresholds. The location already had a high pre-project background level (45.9 µg/m³), indicating existing air quality issues exacerbated by the project.

To mitigate impacts in Hacıali, the following actions are recommended:

- Restrict dust-generating activities during poor dispersion conditions
- Apply water spraying, soil stabilization, and road paving
- Cover all transport vehicles
- Use wind barriers or vegetation buffers
- Relocate dust-intensive activities where feasible
- Implement PM_{10} monitoring in the area

Most locations comply with IAPCR, EU, and IFC standards. While temporary exceedances may occur, especially in Hacıali, the overall impact is not expected to cause lasting degradation of air quality if proposed mitigation measures are properly implemented.

Table X.13 Cumulative Impact Assessment with Maximum PM_{10} GLC Values Measurement Points

District	Baseline Measurements PM_{10} Results (µg/m³)	Scenario 1-2 Max Daily Model Result (µg/m³)	Cumulative PM_{10} (µg/m³)	Number of Exceedances

$PM_{2.5}$ Concentrations at Ground Level

Maximum ground-level PM2.5 concentrations (GLC) were calculated based on the defined scenarios for the area surrounding the existing facilities, and the resulting data were evaluated. The spatial distribution of modeled PM2.5 concentrations is presented in Figure X.14 and Figure X.15. The analysis indicates that in areas with intensive construction activities, the IFC daily limit of 25 µg/m³ is exceeded. As shown in Table X.14, under Scenario 4, the daily PM2.5 concentration reaches 142.58 µg/m³, which significantly exceeds the applicable threshold. In contrast, annual average concentrations generally remain below both the EU annual limit of 25 µg/m³ and the more stringent IFC limit of 10 µg/m³. These findings suggest that PM2.5 impacts are primarily short-term and localized, with limited long-term effects. In areas where the daily limits are exceeded, particularly near construction sites, the implementation of effective dust suppression and emission control measures is essential (see Section X.1.4.1).

Table X.14 Results Of Ground-Level $PM_{2.5}$ Concentrations Observed in Different Scenarios

Scenario	$PM_{2.5}$ Highest Daily (µg/m³)	$PM_{2.5}$ Highest Annual (µg/m³)	UTM WGS 84 ZONE 36 Coordinates (Daily / Annual)	Distance (m)	Direction (from Emission Source to GLC)

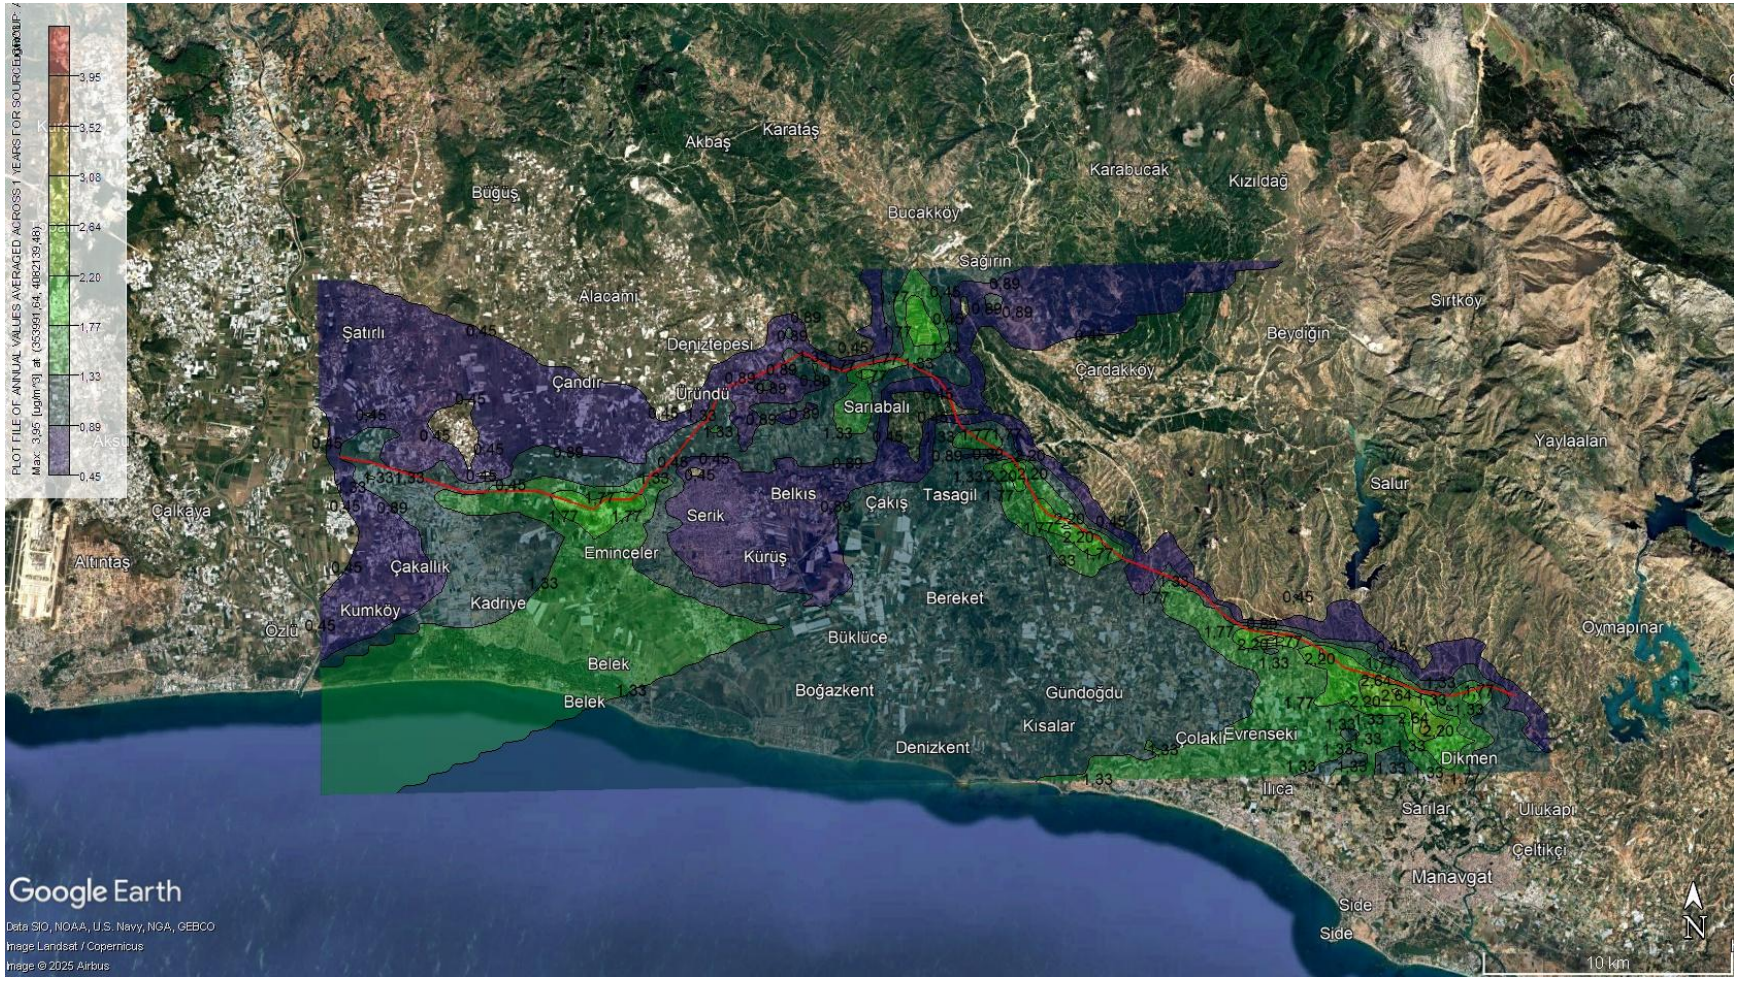

Figure X.14 Maximum annual $PM_{2.5}$ emission distribution-Section1 (µg/m^3)

Figure X.15 Maximum annual $PM_{2.5}$ emission distribution-Section2 (µg/m^3)

This study evaluated the cumulative impact of the project on ambient $PM_{2.5}$ concentrations by combining background measurements with maximum annual modeled values (Scenarios 3–4) at each monitoring location (see Table X.15).

An assessment of the cumulative impacts of the project on ambient air quality reveals that at most monitoring locations, the annual total PM2.5 concentrations remain below both EU and IFC thresholds. However, at the Hacıali monitoring station, due to high baseline concentrations, the total annual PM2.5 level reaches 32.22 µg/m³ despite the project's relatively minor contribution, thereby exceeding both regulatory limits. As presented in Table X.15, at the Sarıabalı station, the project's maximum daily contribution is 62.04 µg/m³, and when combined with background levels, the total daily concentration could reach 72.24 µg/m³—nearly three times the IFC daily limit. Similarly, at Akdam and Karakaya, project-related daily contributions are calculated as 27.24 µg/m³ and 28.44 µg/m³, respectively, both of which exceed the IFC's daily standard.

Mitigation measures to reduce construction-related $PM_{2.5}$ emissions are provided in detail in Section X.1.4.1.

Settled Dust Concentrations at Ground Level

Settled (deposited) dust emissions were also evaluated for the construction-phase scenarios (Scenario 17 and 18) to assess the potential for particulate accumulation at ground level. According to the modeling results presented in Table X.16, the maximum daily settled dust concentration reached 203.53 mg/m²day in Section 1 and 324.66 mg/m²day in Section 2. The corresponding maximum annual average concentrations were calculated as 24.82 mg/m²day and 25.35 mg/m²day, respectively. Additionally, the spatial distributions of modeled settled dust emission under all scenarios are illustrated in Figure X.16 to Figure X.19.

All modeled values remain well below the national IAPCR limit values of 390 mg/m²day for daily and 210 mg/m²day for annual settled dust concentrations. These results indicate that, although visible particulate deposition may occur near active construction zones, the overall impact of settled dust remains within permissible regulatory thresholds, supporting the conclusion that the project is unlikely to cause excessive ground-level dust accumulation under the modeled conditions.

Table X.16 Results of ground-level Settled dust concentrations observed in different scenarios

Scenario	Highest Daily Concentration (mg/m²·day)	UTM WGS 84 ZONE 36 Coordinates (Daily)	Highest Annual Concentration (mg/m²·day)	UTM WGS 84 ZONE 36 Coordinates (Annual)	Distance (m)	Direction (from Emission Source to GLC)
Scenario 17 Construction-Section1	203.53	(337884, 4093014)	24.82	(335987, 4093226)	25 / 160	Southeast / Northeast
Scenario 18 Construction-Section2	324.66	(365419, 4075930)	25.35	(377919, 4066430)	545 / 205	Southwest / Northwest

Figure X.16 Maximum daily settled dust emission distribution - Section1 - Construction (mg/m²day)

Figure X.17 Maximum annual settled dust emission distribution - Section1 - Construction (mg/m^{2}day)

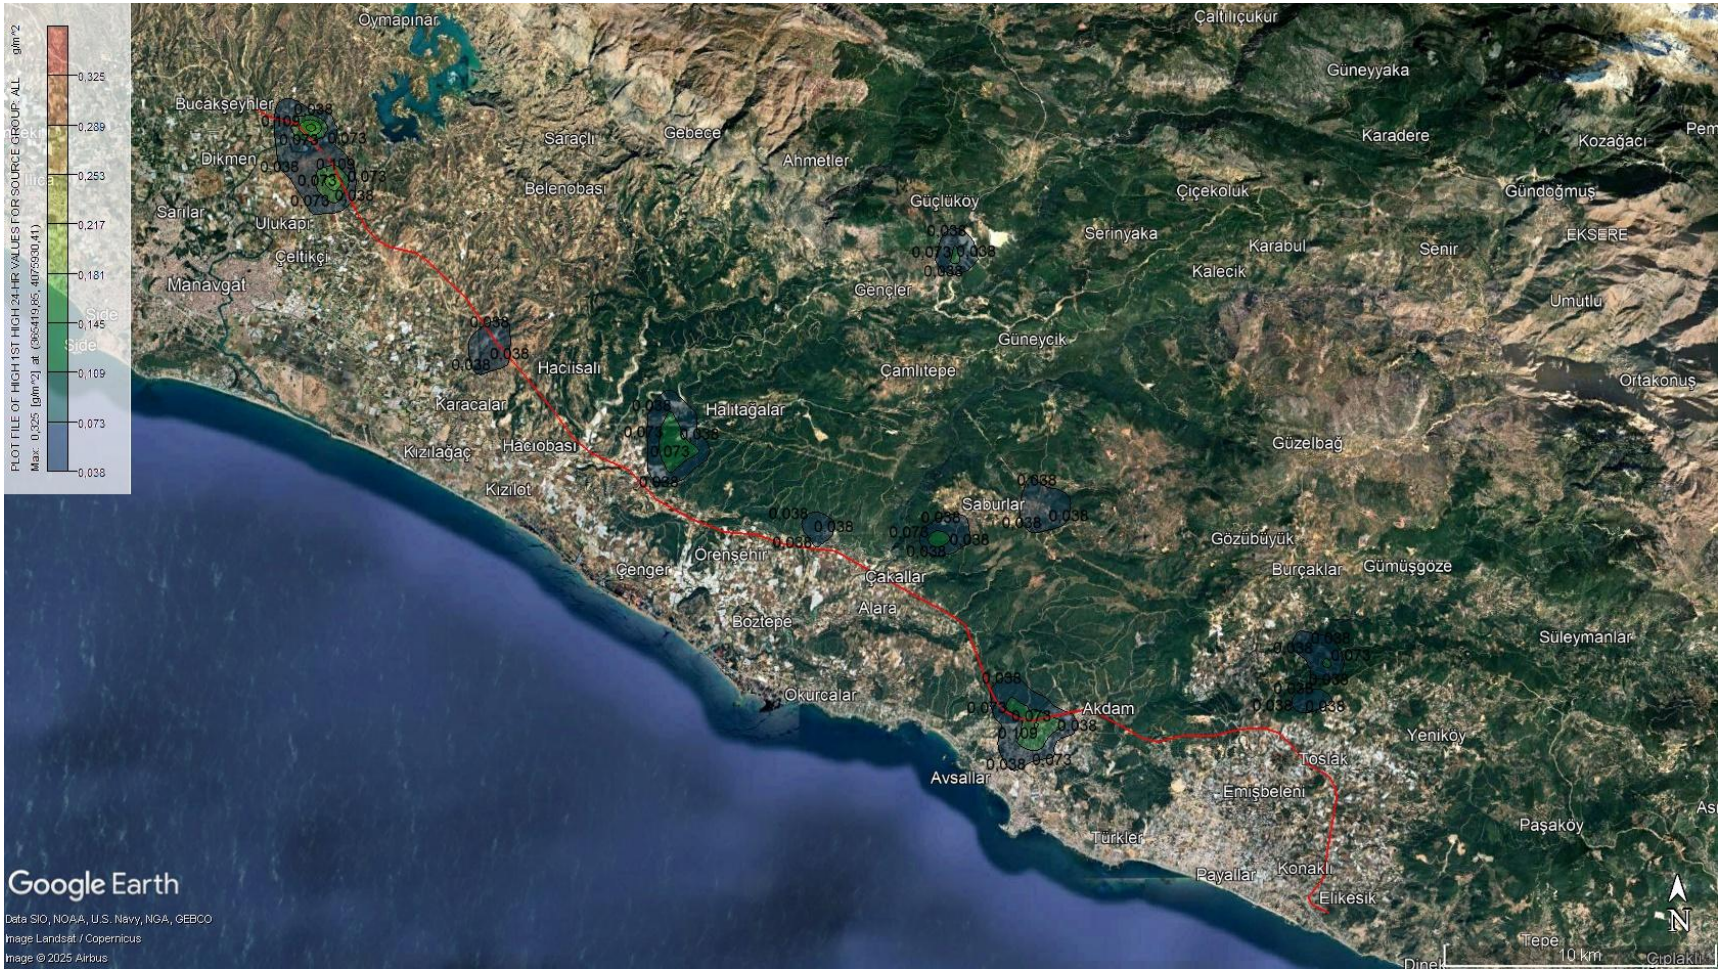

Figure X.18 Maximum daily settled dust emission distribution - Section2 - Construction (mg/m^{2}day)

Figure X.19 Maximum annual settled dust emission distribution - Section2 - Construction (mg/m²day)

The cumulative impact of the project on settled dust concentrations was also evaluated for each monitoring location under Scenarios 17 and 18, as presented in Table X.17. The results reveal spatial variability in deposition levels, reflecting the proximity to active construction areas and unpaved haul roads.

The highest cumulative settled dust concentrations were observed in Sarıabalı (276.59 mg/m²·day), followed by Ulukapı (218.19 mg/m²·day) and Hacıali (112.48 mg/m²·day). These locations are either directly adjacent to intense earthmoving operations or located downwind of major activity centers. While the daily maximum settled dust concentrations at individual receptor points in Sarıabalı (203.53 mg/m²·day) and Ulukapı (144.57 mg/m²·day) remain well below the IAPCR daily limit of 390 mg/m²·day, they represent the highest localized exposure.

Even in the most affected settlements, such as Sarıabalı, Ulukapı, and Hacıali, cumulative concentrations remained below regulatory thresholds. This indicates that construction-related settled dust emissions are not expected to cause long-term air quality degradation or regulatory non-compliance. Overall, these results confirm that, under the modeled scenarios, the project complies with national standards for settled dust, and the anticipated impacts are localized, temporary, and manageable with routine dust suppression measures.

NO_2 Concentrations at Ground Level

The GLC values of NO_2 for the defined scenarios are presented in Table X.18, with spatial distributions shown in Figure X.20 through Figure X.23.

The NO_2 measurements conducted under Scenario 13 (Construction – Section 1) and Scenario 15 (Construction – Section 2) remain well below all relevant national (IAPCR), international (EU Directives), and IFC standards. The maximum hourly concentrations recorded were 175.32 µg/m³ and 126.10 µg/m³ respectively, both below the 200 µg/m³ legal limit, with no exceedances observed in either case. Additionally, the maximum annual average concentrations 5.41 µg/m³ for Scenario 13 and 3.28 µg/m³ for Scenario 15 are significantly lower than the 40 µg/m³ threshold. These results indicate that the construction activities do not pose a significant risk to air quality in terms of NO_2 emissions and are fully compliant with applicable environmental standards. Therefore, NO_2 emissions are not anticipated to cause any adverse effects on the ambient air quality or public health in the surrounding environment.

Table X.18 Results of ground-level NO_2 concentrations observed in different scenarios

Scenario	Maximum Hourly Concentration (µg/m³)	UTM WGS 84 ZONE 36 Coordinates (Hourly)	Number of Exceedances	Maximum Annual Concentration (µg/m³)	UTM WGS 84 ZONE 36 Coordinates (Annual)	Distance (m)	Direction (from Emission Source to GLC)

Figure X.22 Maximum hourly NO_2 emission distribution Section 2- Construction (µg/m^3)

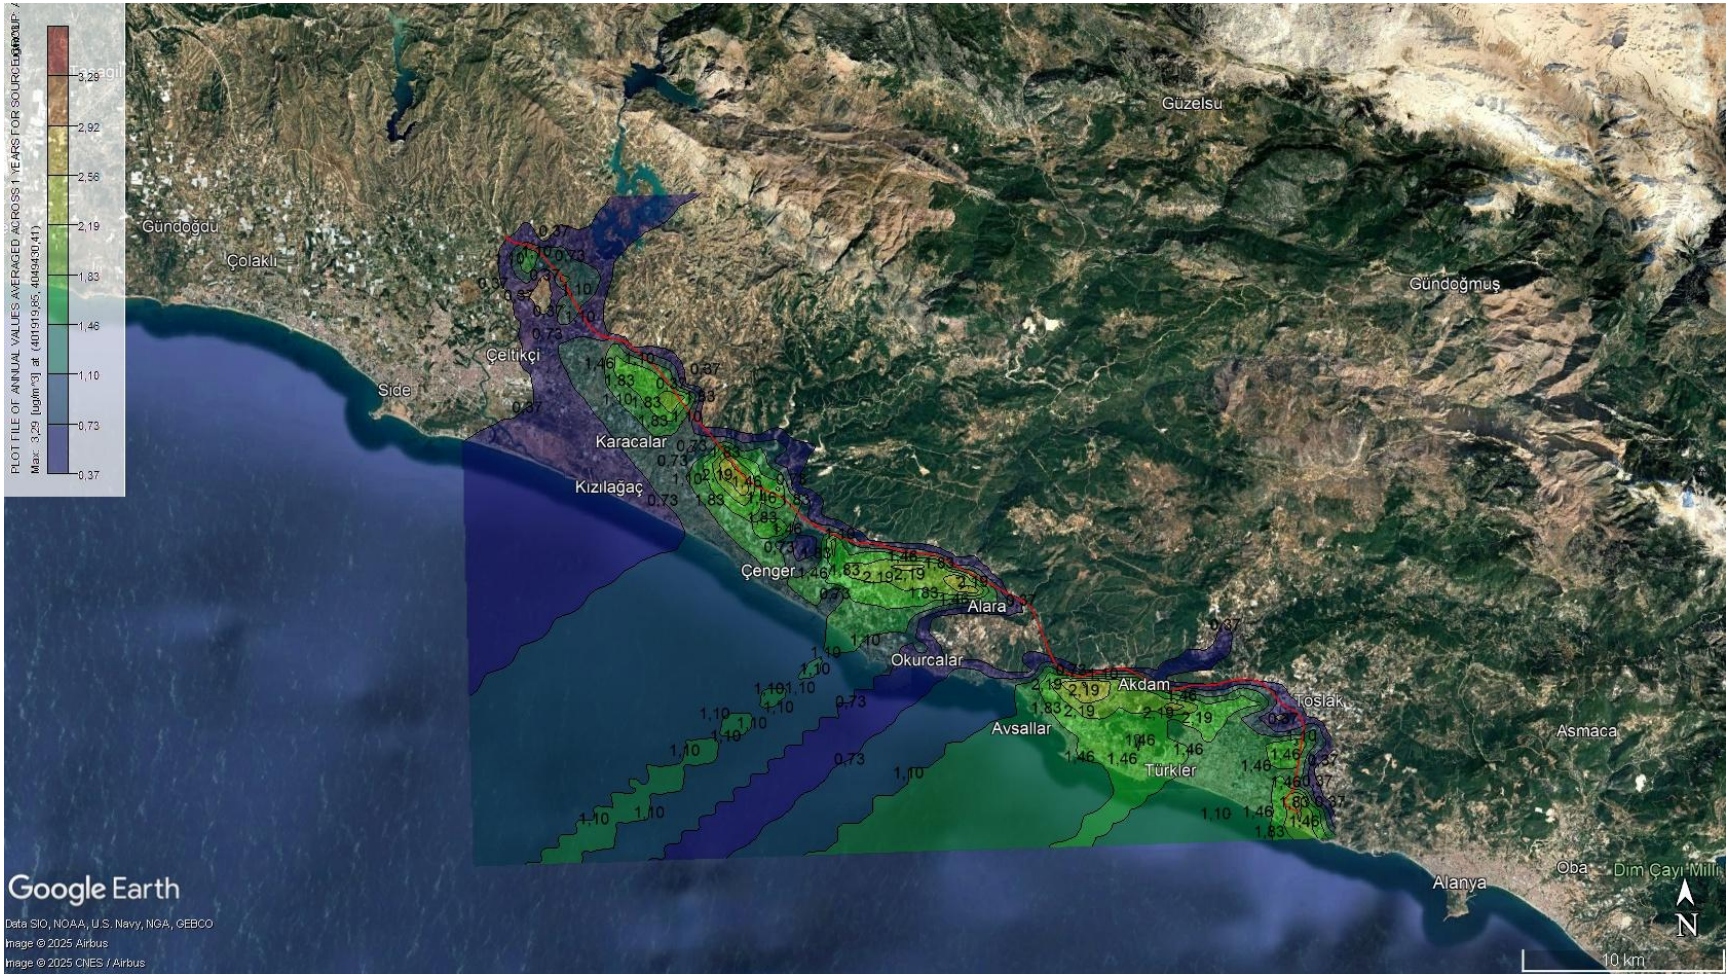

Figure X.23 Maximum annual NO_2 emission distribution Section 2- Construction (µg/m³)

As previously noted, background air quality measurements were conducted at multiple locations across the region. Cumulative NO_2 concentrations were then calculated by combining these background values with the maximum hourly modeled concentrations. Results are provided in Table X.19 (construction phase).

Similarly, Table X.19 shows that during the construction phase, cumulative NO_2 concentrations including emissions from non-road mobile construction machinery also stay below the 200 µg/m³ limit. The highest recorded value was 44.55 µg/m³ in Taşağıl, and no exceedances occurred at any receptor point.

In both phases, the cumulative concentrations confirm compliance with applicable NO_2 standards, and no exceedance of regulatory thresholds is anticipated at any of the assessed locations.

CO Concentrations at Ground Level

The GLC values of CO for the defined scenarios are presented in Table X.20, with spatial distributions shown in Figure X.24 and Figure X.25.

For the construction phase, Scenario 14 (Section 1) showed a maximum CO concentration of 1,082.06 µg/m³, and Scenario 16 (Section 2) showed 670.32 µg/m³. All values are significantly lower than the legal threshold, with no exceedances recorded.

In conclusion, modeled CO concentrations from both traffic and construction activities remain far below national air quality limits, and CO emissions are not expected to adversely impact ambient air quality or human health.

Table X.20 Results of ground-level CO concentrations observed in different scenarios in Construction Phase

X.1.3.2. Operation Phase

This section summarizes the emissions expected during the operation phase of the planned project, along with the mitigation measures intended to minimize them. Due to the AERMOD model's 50 km spatial limitation and the linear extent of the project, the motorway was modeled in two segments referred to as Section 1 and Section 2 throughout the report.

Operational emissions of NO_2, CO, PM_{10}, and VOCs are primarily associated with vehicle traffic on the motorway. These emissions were estimated using emission factors provided in the EMEP/EEA 1.A.3.b.i–iv Road Transport Guidebook, detailed in Table X.22 through Table X.26 for various vehicle categories. Although the project is located in Türkiye, internationally recognized emission factors were used—specifically, Australian emission factors—due to their applicability to construction-related conditions and their consistency with global modeling practices. This approach reflects standard practice in Turkish EIA studies, particularly when local factors are either generalized or not representative of specific activities.

Vehicle traffic projections for the year 2040 the worst-case scenario in terms of traffic volume were used as the basis for emission calculations. Dust emissions were not modeled in the operation phase, as they are significantly lower than those in the construction phase. According to guidance from the UK Standards for Highways (LA 105, 2024)[7], where air quality thresholds for particulate matter are not exceeded in the base year, detailed modeling of PM_{10} or $PM_{2.5}$ during the operation phase is generally not required. Given that vehicle movements occur on fully paved surfaces and fugitive dust generation is minimal, operation-phase dust modeling is considered unnecessary for this project.

SO_2 emissions were excluded from the dispersion modeling, as they are considered negligible. This is based on the assumption that all vehicles will comply with Euro V or later standards and will use ultra-low sulfur diesel (<10 ppm sulfur), in line with the EMEP/EEA Guidebook. Accordingly, exhaust-related SO_2 emissions are not expected to significantly contribute to ambient concentrations.

Emission estimations by vehicle type and traffic volume, using the aforementioned emission factors, are detailed in the subsequent section.

Other	2,643	3,135	3,361	3,542	3,723	3,896	4,086	4,286	4,507	4,718	4,951	5,196	5,465
Total AADT PCU	**25007**	**30,802**	**35,574**	**37,902**	**39,961**	**41,952**	**44,151**	**46,474**	**49,039**	**51,525**	**54,269**	**57,170**	**60,372**

As part of the air quality dispersion modeling, the year 2040 was selected to represent the peak operational emissions scenario based on projected traffic activity. The projected AADT (Annual Average Daily Traffic) is 60,372 PCU (Passenger Car Units), distributed across five vehicle categories: cars, small trucks (S-TR), buses, trucks, and other vehicles.

To ensure accurate emissions estimates, the modeling incorporated a realistic and policy-aligned projection of vehicle and fuel type distributions for 2040. Although not based on an official government forecast, the scenario reflects strategic decarbonization goals, technological trends, and national statistical data.

Aligned with Türkiye's 2053 carbon neutrality target, the assumed 2040 fleet composition adopts a cautious yet evidence-based approach. For example, a 40% electric vehicle (EV) share is assumed for passenger cars—lower than SHURA's projection of 50% EV share by 2035—to account for possible delays in infrastructure and adoption. For urban buses, a 60% EV share was used, consistent with EU targets and domestic electrification trends in public transport.

Petrol-fueled cars are expected to maintain a substantial share of the fleet. Reflecting current data from TÜİK (2023–2025), petrol vehicles are projected to represent 35% of passenger cars in 2040, especially in mid-range and aging vehicle segments. Diesel remains dominant in freight and utility transport due to its efficiency and durability. Diesel shares are assumed to be 20% for passenger cars, 65% for small trucks, 90% for trucks, 40% for buses, and 95% for off-road vehicles.

Although the share of LPG vehicles is expected to decline with electrification, a residual 5% LPG share is retained for passenger cars, considering ongoing use in cost-sensitive market segments and legacy vehicles.

The detailed propulsion-type and fuel distribution assumptions are presented in Table X.22. These values are not forecasts but rather plausible planning assumptions, based on current statistics (TÜİK, EMRA), national climate strategies (MoEUCC), and international sources such as SHURA, ICCT, and IEA. They aim to balance policy ambition with technical and market realities in Türkiye's evolving transportation landscape.

Air Quality Modeling for Operation Phase

In order to evaluate the potential operation phase impacts of the Project, air quality modeling was carried out for NO_2, VOC, SO_2 and CO parameters. The Air Quality Modeling Report was presented as an Annex of this report. Within the scope of the modeling studies, hourly and annual concentrations were determined and compared with air quality limit values defined in the Regulation on Assessment and Management of Air Quality, Industrial Air Pollution Control Regulation, and IFC standards (see Table X.1, Table X.2 and Table X.3).

For each pollutant, modeling studies will be carried out under various scenarios and the possible effects of pollutant sources on local air quality will be examined according to each scenario. Based on the determined scenarios for operation phase, the ground level concentration (GLC) values of the measured parameters along the route will be provided in this subsection.

Emissions of Car type vehicles

In this study, category-specific assumptions were made using Türkiye's 2040 projections, which reflect trends in electrification and alternative fuels.For passenger cars, the projected 2040 fuel distribution is as follows:

- Electric Vehicles (EV): 40.0%
- Petrol: 35.0%
- Diesel: 20.0%
- LPG: 5.0%

The total daily vehicle count and its breakdown by subcategory used for emission factor calculations are shown in Table X.27, and the resulting emission rates are provided in Table X.28. To model traffic-related emissions during the operation phase, pollutant-specific emission rates were calculated for each vehicle type based on projected annual traffic data and corresponding emission factors. These rates were then converted to per-second values and adjusted using a spatial normalization factor, allowing them to be used as area sources in the dispersion model. This method ensures accurate and consistent representation of traffic emissions across the modeling area.

Emissions of Light Commercial Vehicles

For light commercial vehicles (S-TR), fuel type assumptions were revised using 2040 projections. The projected distribution is as follows:

- Electric: 20.0%
- Petrol: 15.0%
- Diesel: 65.0%

The number of vehicles, based on these assumptions, is presented in Table X.29 for both the first and second sections. Emission values calculated using the vehicle counts and corresponding fuel types are provided in Table X.30.

VOC	0.0015

Emissions of Trucks

In the 2040 vehicle projection data used for this study, freight vehicles are divided into two categories: “Truck” and “Other”, to apply weight-specific emission factors accurately during modeling.

The “Truck” category includes light and medium-duty freight vehicles with a gross vehicle weight of 7.5 tons or less, such as local delivery trucks and service vehicles.

The “Other” category consists of heavy-duty vehicles over 7.5 tons, including long-haul trucks, construction vehicles, and high-capacity freight haulers.

Fuel Type Distribution (2040 Projections for Türkiye):

Truck (≤7.5 t):

- Electric: 10%
- Diesel: 90%

Other (>7.5 t):

- Electric: 5%
- Diesel: 95%

Vehicle counts based on these assumptions are shown in Table X.33, and the corresponding emission values by fuel type are presented in Table X.34.

NO_2 Concentrations at Ground Level

Table X.35 presents the ground-level NO_2 concentrations (GLC) for each scenario, with distribution maps shown in Figure X.26 to Figure X.29. In Scenario 5 (Operational – Section 1), The NO_2 measurements for Scenario 5 (Operational – Section 1) and Scenario 8 (Operational – Section 2) are well within the limits set by national (IAPCR), EU, and IFC standards. In Scenario 5, the maximum hourly concentration is 11.81 µg/m³ and the maximum annual average is 0.36 µg/m³; in Scenario 8, the hourly and annual values are 8.54 µg/m³ and 0.22 µg/m³, respectively. No exceedances of the hourly limit (200 µg/m³) were recorded in either scenario, and the annual concentrations are far below the 40 µg/m³ threshold. These findings indicate that operational activities contribute minimally to NO_2 levels and fully comply with environmental air quality standards. These results demonstrate that project-related NO_2 emissions during operation will remain well within legal thresholds and are not expected to negatively impact air quality or public health.

Table X.35 Results of ground-level NO_2 concentrations observed in different scenarios

Scenario	NO_2 Maximum Hourly Concentration (µg/m³)	Number of Exceedances	NO_2 Maximum Annual Concentration (µg/m³)	UTM WGS 84 ZONE 36 Coordinates (Hourly / Annual)	Distance (m)	Direction (from Emission Source to GLC)

Figure X.28 Maximum hourly NO2 emission distribution Section 2 - Operation (µg/m^3)

Figure X.29 Maximum annual NO_2 emission distribution Section 2- Operation (µg/m³)

As detailed in Table X.36, cumulative NO_2 concentrations were calculated by adding background measurements to the modeled maximum hourly values. All locations recorded values well below the IAPCR hourly limit of 200 µg/m³, with no exceedances observed. The highest concentration was in Taşağıl at 6.96 µg/m³, which is significantly lower than the regulatory threshold. Other locations ranged between 4.50 and 6.39 µg/m³, confirming that the project's impact on NO_2 levels is minimal and fully compliant with air quality standards.

Table X.36 Impact Assessment with Maximum NO_2 GLC Values-Measurement Points

CO Concentrations at Ground Level

Table X.37 presents the modeled CO concentrations for each scenario, with spatial distributions shown in Figure X.30 and Figure X.31. In Scenario 6 (Operational – Section 1), the maximum 8-hour average CO concentration was 3.55 µg/m³, while in Scenario 9 (Operational – Section 2), it was 2.21 µg/m³. Both values are far below the IAPCR limit of 10,000 µg/m³ (8-hour average), and no exceedances were observed. These results show that CO emissions from project-related traffic and operations are minimal and pose no risk to air quality or public health.

Table X.37 Results of ground-level CO concentrations observed in different scenarios

Scenario	UTM WGS 84 ZONE 36 Coordinates		CO	Distance (m)	Direction (from Emission Source to GLC)
	X	Y	Highest Daily 8-Hour Average (µg/m³)

Figure X.30 Maximum 8-hour CO emission distribution Section 1 (µg/m³)

Figure X.31 Maximum 8-hour CO emission distribution Section 2 (µg/m³)

Ground Level VOC Concentrations

Table X.38 shows that the highest modeled VOC concentrations are well below IAPCR limits. In Scenario 7 (Operational – Section 1), the maximum hourly value was 2.43 µg/m³ and the daily value was 0.35 µg/m³. For Scenario 10 (Operational - Section 2), the hourly and daily concentrations were 1.76 µg/m³ and 0.22 µg/m³, respectively. All values fall significantly below the regulatory thresholds of 280 µg/m³ (hourly) and 70 µg/m³ (daily). VOC distribution maps are shown in Figure X.32 through Figure X.35. These results confirm that VOC emissions from project operations will not negatively impact air quality or public health.

This study used the AERMOD dispersion model to assess the short- and long-term air quality impacts of emissions from both the construction and operation phases of the Antalya–Alanya Motorway Project, focusing on PM_{10}, $PM_{2.5}$, settled dust, NO_2, CO, and VOCs under eighteen different scenarios.

Conclusion

In this study, air quality modeling was conducted to assess the short- and long-term impacts of emissions from both the construction and operation phases of the Antalya-Alanya Motorway Project. The dispersion of pollutants (PM_{10}, $PM_{2.5}$, settled dust, NO_2, CO, VOC) was simulated using the AERMOD model under eighteen different scenarios.

During the construction phase, the highest daily PM_{10} concentrations reached 1,219.87 µg/m³ (Section 2) and 559.07 µg/m³ (Section 1). Despite these high short-term peaks in localized areas, the number of daily exceedances (34 and 33 days) remained within the legal threshold of 35 days/year (IAPCR), and annual averages were well below the 40 µg/m³ limit. This indicates that construction-related dust emissions are temporary, localized, and compliant with regulations.

Annual $PM_{2.5}$ concentrations were low (max 3.34 µg/m³ in Section 2), significantly below the 20 µg/m³ limit. However, in Hacıali, where the background concentration was already 30.5 µg/m³, the project's contribution raised the cumulative value to 32.22 µg/m³, exceeding the regulatory limit. This suggests that Hacıali is a pre-existing air quality hotspot.

The maximum daily settled dust concentration was calculated as 203.53 mg/m²day in Scenario 17 (Construction – Section 1) and 324.66 mg/m²day in Scenario 18 (Construction – Section 2). Corresponding maximum annual average concentrations were 24.82 mg/m²day and 25.35 mg/m²day µg/m³, respectively. All modeled values remained well below the IAPCR regulatory thresholds of 390 mg/m²day for daily and 210 mg/m²day for annual settled dust concentrations. These results indicate that, under both construction scenarios, settled dust levels do not pose a risk of long-term accumulation or regulatory exceedance.

The highest cumulative settled dust concentration was observed in Sarıabalı, with a total of 276.59 mg/m²day, followed by Ulukapı (218.19 mg/m²day) and Hacıali (112.48 mg/m²day). These locations are either directly adjacent to intense earthmoving operations or located downwind of major activity centers. Although the daily maximum settled dust concentrations at individual receptor points in Sarıabalı (203.53 µg/m³) and Ulukapı (144.57 mg/m²day) remain well below the IAPCR daily limit of 390 mg/m²day.

NO_2 hourly and annual concentrations during both phases remained well below the legal thresholds (200 µg/m³ hourly, 40 µg/m³ annual), with no exceedances. Emissions during the operation phase were even lower, confirming minimal contribution to NO_2 pollution.

CO concentrations remained very low in both phases, with maximum 8-hour values far below the 10,000 µg/m³ limit, indicating negligible health risk.

VOC levels were also minimal (≤1.05 µg/m³), and although no specific regulatory threshold applies, these concentrations are not expected to impact air quality or health.

In conclusion, the project's emissions are within national and international air quality standards. Apart from localized and short-term peaks during construction, particularly in areas with already high background levels like Hacıali, the overall environmental impact is limited.

Recommendations:

- Implement dust suppression measures (e.g., water spraying, truck covering, activity limits in dry/windy weather), particularly in high PM_{10} zones.
- Establish continuous air quality monitoring in areas such as Hacıali to track cumulative impacts and inform mitigation.

X.1.4. Mitigation Measures

The following sections describe the actions and strategies designed to avoid, minimize or offset the potential adverse air quality impacts of the Project, or to enhance potential Project benefits.

X.1.4.1. Land Preparation and Construction Phase

As outlined in the preceding sections, construction activities will result in dust emissions due to excavation, filling, and material handling and storage, as well as exhaust emissions from diesel-powered construction machinery and equipment. To minimize and control these air emissions, the following measures will be implemented during the land preparation and construction phases, in accordance with applicable Turkish regulations, EU Directives, IFC Standards, and KGM's Technical Specifications for Motorways.

Baseline air quality monitoring studies have been assessed as sufficient, with detailed explanations and evaluations provided in Section X.1.2 of the ESIA Report. These studies meet the requirements of IFC Performance Standards and relevant environmental regulations. Furthermore, regular air quality monitoring will be carried out throughout the construction phase. Accordingly, no additional pre-construction air quality monitoring is considered necessary. The air quality monitoring approach—including the parameters to be measured and the monitoring frequency—is described in detail in the Monitoring Plan section (Chapter XX) of the ESIA Report.

Material Handling and Process Emissions

- Dust emissions from sources such as conveyors, bins, and crushing-screening plants will be controlled through enclosures, covers, and dedicated dust suppression systems (e.g., water sprays, baghouse filters, or cyclones).
- All dust-emitting units within crushing-screening operations will be placed in enclosed structures equipped with appropriate dust control systems.
- The drop height of fine or dusty materials during loading/unloading will be minimized to reduce airborne dust.
- Loading and unloading operations will be conducted without scattering or throwing materials.

Open Area and Road Dust Controls

- Open sources such as material stockpiles will be managed using covers, enclosures, or by maintaining adequate moisture content.

- Dust suppression measures including regular watering using water trucks or pressurized spraying systems will be applied on construction sites, service roads, access roads, and at quarry or storage areas. These measures will be enforced as needed, including nights, weekends, and non-working days.
- Speed limits for all construction vehicles will be established and enforced to minimize dust resuspension.
- Project roads, especially those accessing quarries, will be upgraded and widened where necessary to support safe, low-dust vehicle movement.
- If nearby roads are actively used by traffic, continuous dust suppression will be applied to maintain safety and visibility. On unused roads, dust control will focus on residential and commercial areas.

Transport and Vehicle Controls

- All trucks transporting excavated or raw materials will be covered with nylon tarpaulin.
- Construction vehicles will not be permitted to idle unnecessarily on- or off-site.
- Only well-maintained vehicles and machinery will be used. A regular maintenance program will be in place to ensure engine efficiency and minimize emissions.
- Preference will be given to locally licensed quarries to reduce transportation distances and related emissions.
- Driving through residential settlements will be avoided when alternative routes exist.
- Exhaust emission measurements of the vehicles will be conducted periodically every three months.

Blasting Activities

- Blasting operations will be conducted in full compliance with applicable regulations and aligned with industry best practices to minimize short-term dust releases.

Dust Barrier and Wind Protection

- Windbreaks, fences, or vegetative barriers will be installed around material storage areas and other emission-prone zones to reduce dust dispersion.

Monitoring and Compliance

- Air quality management will comply with the “Regulation on the Control of Industrial-Sourced Air Pollution” and the “Regulation on the Assessment and Management of Air Quality.”
- PM_{10} measurements will be carried out in or near sensitive areas, particularly in Hacıali (monthly monitoring and more frequent monitoring if needed, depending on the intensity of construction work, weather conditions, etc.); this will enable rapid response to exceedances and the development of adaptive dust management strategies.

Site-Specific Measures for Hacıali

Given the already high background PM concentrations and projected exceedance levels in Hacıali, additional targeted mitigation is required:

- Dust-generating activities will be limited during stagnant meteorological conditions (e.g., inversions or low wind scenarios).
- Intensive dust-producing operations will be relocated away from Hacıali where technically and logistically feasible.
- Road paving and soil stabilization techniques will be employed to reduce dust lift-off.
- The use of wind barriers or vegetation buffers will be prioritized between emission sources and residential receptors in Hacıali.
- Any verified environmental damage due to insufficient dust control will be subject to compensation and corrective action.
- An air quality monitoring station will be established in Hacıali neighborhood to monitor potential impacts.

X.1.4.2. Operation Phase

At the service areas, a green buffer strip will be formed between the outer lane of the Motorway and the facilities. This strip will be properly planted (e.g. with shrubs that start growing from the base and are resistant to dust and gaseous emissions) to form a barrier against dust to be sourced from the Motorway's vehicle traffic.

The application of automatic toll systems along the Motorway will contribute to an optimization of traffic flows and thus lower emissions.

X.1.5. Summary of Assessments and Residual Impacts

Table X.70 provides a summary on the air quality assessments. Significance of the identified impacts before and after the implementation of mitigation measures are summarized in this table. As can be seen from the Table, potential impacts on local communities are assessed as low during land preparation and construction phase of the motorway while it is anticipated that these impacts would be lower with mitigation measures to be applied. During operation of the motorway, medium and high level impacts are anticipated to result in residual impacts of medium and low with relevant mitigation measures. Furthermore, already existing traffic load on alternative roads will shift on to Antalya-Alanya Motorway and it is anticipated that emissions from these roads will decrease. It should also be noted that high impact significance (for sensitive receptors) is mainly attributed to the baseline air quality measured at sensitive receptors which reflect exceedance of air quality standards. In this context, additional site-specific mitigation and continuous monitoring will be implemented in Hacıali, where baseline concentrations are already elevated.

X.2. Climate Change

This subsection focuses on the two-way relationship between the Project and climate change. First, the section assesses the potential impacts of the Project on greenhouse gas emissions and consequently, on climate change. Second, the section evaluates the potential vulnerabilities of the Project due to the effects of the changing climate. The Project Sponsor has determined a total of 15

years, 3 years for construction and 12 years for operation and after it will post-handover to the Turkish General Directorate for Highways (KGM) until it's end of life likely after 2051 which 0% carbon emission in Türkiye takes place.

The Project's Impact on Climate Change

The Project's contribution to the climate change will primarily result from the emissions of greenhouse gases (GHGs). During the construction phase, the majority of GHG emissions will be generated by the use of construction machinery and equipment. However, during operation phase of the Project most vehicle traffic will be diverted to the new Motorway from existing roads, except in areas where access to new regions will be enhanced by the Project, the overall change in GHG emissions due to vehicle traffic is expected to be minimal. Still, GHG emissions are expected from operation phase facilities such as toll plazas, service and maintenance areas, and weigh stations, roadside assistance centers. These emissions mainly stem from shuttle services for personnel transportation, emergency, repair and maintenance tools, equipment and vehicles (angle grinder, asphalt paver, bitumen kettle, stone cutter, emergency generators, all combustion engine vehicles etc.) and energy consumption of the operation phase facilities, including electricity and heating.

The ultimate source of CO_2 emissions involves three primary contributors: fuel combustion, material combustion, and the introduction of carbon-containing substances from combustion engine exhausts to the atmosphere (EMEP/EEA Air Pollutant Emission Inventory Guide 2016). Global warming potential factors are used to convert GHG emissions to CO_2 emissions in order to assess the global warming potential of a GHG in units of CO_2-eq. This approach is developed to allow more accurate, easier and objective evaluation of GHGs by bringing them to a common unit, CO_2 equivalent of the GHG (CO_2-eq).

Climate Change's Impact on the Project

The effects of climate change vary across geographical regions. The changes cause permanent flooding from elevated water levels or heightened risks of flash floods due to changes in precipitation regime in certain areas, while marginal temperature increase, fires, drought and desertification in others. Therefore, the Project location is determined as the most important parameter for the effects of climate change on the Project and the assessment was made specific to the Project location. In this subsection, following the assessment of the Project's impact on climate change, an assessment of the potential impacts of climate change on the Project location, and thus on the Project itself, over its lifespan was provided. The assessment utilizes data and information from the World Bank Climate Change Portal. Based on the credible information provided, a "Project Climate Vulnerability Assessment" was provided with possible climate change impacts on the Project and mitigation measures were outlined to mitigate and/or minimize the potential effects.

X.2.1. Assessment Methodology and Data Sources

The Project is considered having the potential to emit one or more of the greenhouse gases (GHGs). GHG assessment for the land preparation and construction phase, and operation phase of the Motorway is carried out in this subsection.

X.2.1.1. Greenhouse Gases

Contribution of Project activities to climate change is evaluated by estimation of the amount of greenhouse gas emissions. Greenhouse gas emissions will be generated during both construction and operation phases of the Project.

Mobile sources and transportation account for a large fraction of fossil fuel combustion in most countries. Internal combustion engines derive energy from burning of hydrocarbon fuel in air, generating carbon dioxide (CO_2) and water vapor (H_2O). During combustion, some amount of the fuel is either not burnt or partially burnt. This results in generation of carbon monoxide (CO), volatile organic compounds (VOCs) and particulate matter (PM).

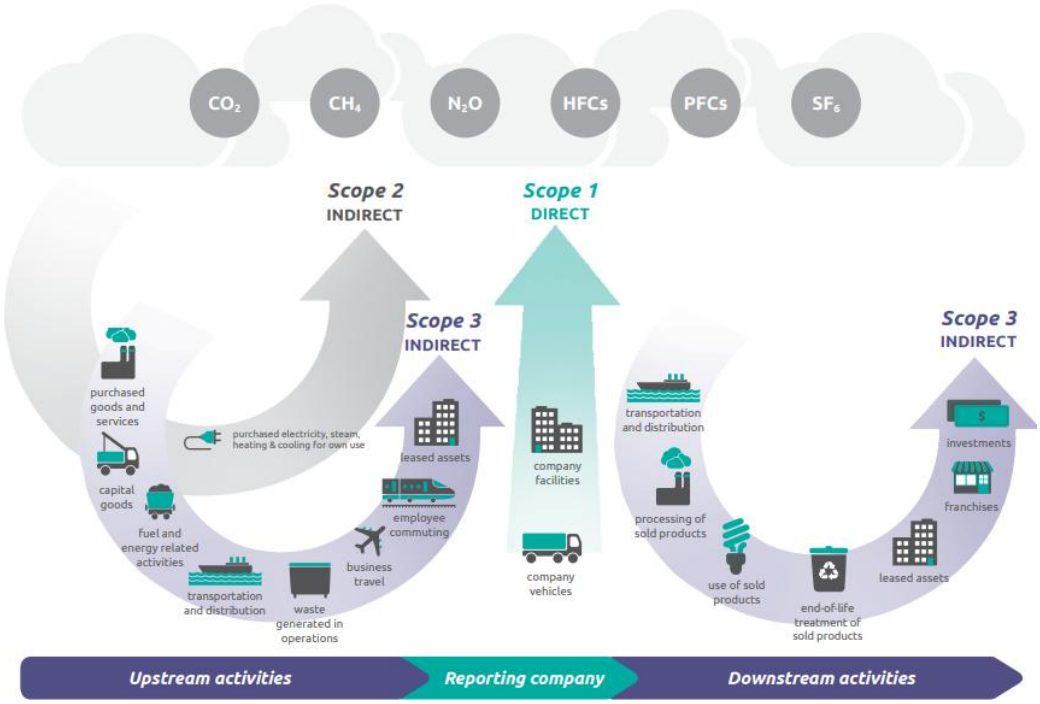
In addition, at the high temperatures and pressures found in the combustion chamber, some of the nitrogen in the air and fuel is oxidized, forming mainly nitric oxide (NO) with a small amount of nitrogen dioxide (NO_2). By convention, the sum total of oxides of nitrogen (i.e. NO + NO_2) is abbreviated as NO_x. To summarize, CO, VOCs, NO_x and PM, have normally been regarded as the pollutants of most concern, and rates of emission are legally restricted in many countries. CO_2, being a major contributor to global warming, is now also considered to be an atmospheric pollutant.

Beyond local air pollution, vehicle emissions also contribute to regional air quality degradation, with greenhouse gases like CO_2, posing long-term environmental challenges on a global scale.

GHG emissions are calculated by applying established emission factors, which are standardized values that associate greenhouse gas emissions with specific activity levels at a given emission source.

Building on this approach, the organizational boundaries for the GHG assessment were defined using the "control principle" outlined in the ISO 14064-1 standard. According to this principle, all emissions from assets and activities under the organization's control must be included in the assessment. In practical terms, this means that only emissions stemming from operations, facilities, or activities directly managed or influenced by the organization; whether through ownership, operational control, or other forms of control, are considered in the GHG inventory. This ensures that the assessment accurately captures the organization's environmental impact.

The operational boundaries for greenhouse gas (GHG) assessment within a corporation are defined by the direct and indirect emissions generated by the Project. These boundaries are classified into three categories: Scope 1, Scope 2, and Scope 3 (Figure X.36).



Source: Corporate Value Chain (Scope 3) Accounting and Reporting Standard

Figure X.36 Overview of GHG Protocol scopes and emissions across the value chain

Scope 1: Direct Emissions

Covers direct emissions from sources owned or controlled by a company.

- Emissions from company-owned vehicles.
- Emissions from fuel burned in facilities, machinery, or heating systems.
- Emissions from on-site waste treatment or industrial processes.

Scope 2: Indirect Emissions from Energy Consumption

These are the emissions that are indirectly caused by a company while producing the energy it imports or purchases and uses.

- Emissions resulting from the electricity consumed in office buildings or production facilities.
- Emissions from purchased heating or cooling used for operations.

Scope 3: Other Indirect Emissions

Includes all other indirect emissions occurring in the value chain that are not produced by the company itself and are not the result of activities arising from assets it owns or controls.

- Emissions from the production of purchased goods and services in the supply chain.

- Emissions from employee business travel or commuting.
- Emissions linked to the transportation of goods or the disposal of waste.

Transition Risks

Transition risks refer to potential challenges the Project may face due to the global and national shift toward a low-carbon and climate-resilient economy. These risks arise from changes in climate-related policies, technologies, market conditions, and stakeholder expectations

They can affect an organization's costs, asset values, business models, and long-term viability, particularly if the entity is slow to adapt to evolving climate requirements or public expectations.

The following Transition Risks may impact the Project:

Regulation Risks:

Changes in laws, regulations or enforcement practices can impact or delay the Project. It can affect the Projects costs, operational requirements, and compliance obligations.

Technology Risk:

Potential losses the Project might face due to technological changes or limitations. These might be due to adopting new technologies, falling behind in a technological way or the technological change of the current system.

Legal Risk:

Potential financial, operational, or reputational impact to the Project resulting from legal actions, non-compliance with applicable laws, and changes in legal and regulatory frameworks.

Market Risk:

Potential financial and operational impacts the Project might face due to changes of the market condition.

Workforce Risk:

Potential challenges that the Project might face due to the availability, capacity, safety, and stability of the labor force.

X.2.1.2. Regulatory Framework

Turkish Legal Requirements

Türkiye became a party of the United Nations Framework Convention on Climate Change in 2004. In the 7th Conferences of the Parties (COP7) meeting held in Marrakech in 2001, the special conditions of Türkiye which has a different position than the other countries in the Annex-I list of the Convention, were recognized and it was decided that its name will remain on the Annex-I while it will be removed from the Annex-II list.

The process that is started when Türkiye is recognized as an Annex-I country having special conditions different from the other parties of the Convention, has affected and accelerated the country's political decision of being a party of the Kyoto Protocol. Around five years after becoming a part of the Convention, in February 2009, "The law on the convenience of Türkiye's entrance to the Kyoto Protocol for the United Nations Framework Convention on Climate Change" came into force, in May 2009; Türkiye's entrance to the Kyoto Protocol was documented and sent to the General Secretariat of the United Nations. The whole ratification process of the Protocol was completed in 26 August 2009.

As a country that ratified the UN Convention Framework on Climate Change and the Kyoto Protocol, Türkiye has taken the responsibilities described under UNFCCC, that are related to the adaptation to the effects of the climate change which are imposed to the parties. The issues of some of the international UN conventions that Türkiye is a party are also indirectly related with the adaptation to the effects of the climate change. These are; Convention to Combat Desertification, Convention on Biological Diversity, Bern Convention on the Conservation of European Wildlife and Natural Habitats, Conventions for the Protection of Mediterranean Sea and the Black Sea Against Pollution and its additional protocols *(Ministry of Environment, Urbanization and Climate Change, 2021).*

Within this scope, adaptation to climate change and actions towards mitigation of potential impacts of climate change are regulated through a variety of national legislation including topics such as disaster risk management, conservation of biodiversity, water safety and security, food safety and security.

IFC Standards

IFC has established the Performance Standards on Environmental and Social Sustainability and relevant guidance notes. IFC Performance Standard (PS) 3 on Resource Efficiency and Pollution Prevention states that; for projects that are expected to or currently produce more than 25.000 tons of CO_2-eq annually, the client will quantify direct emissions from the facilities owned or controlled within the physical project boundary, as well as indirect emissions associated with the off-site production of energy used by the project (IFC PS3, 2012). It suggests the client to consider alternatives and implement technically and financially feasible and cost-effective options to reduce project related GHG emissions during the design and operation of the project which may include, but not limited to, alternative project locations, adoption of renewable or low carbon energy sources, sustainable agricultural, forestry and livestock management practices, the reduction of fugitive emissions and the reduction of gas flaring. Another requirement of PS 3 is quantification of GHG emissions which will be conducted by the client annually in accordance with internationally recognized methodologies and good practice.

Equator Principles IV

The Equator Principles (EP) provides a framework for managing environmental and social risks in project finance. Equator Principle IV on Climate Change specifies that for projects with the potential for significant greenhouse gas (GHG) emissions, the client must conduct a climate change risk assessment. This assessment should evaluate both the project's direct and indirect GHG emissions, as well as its vulnerability to climate-related risks, such as the physical impacts of climate change and transition risks arising from the shift to a low-carbon economy (Equator Principles, 2020).

"The EPFI will require the client to report publicly on an annual basis on GHG emission levels (combined Scope 1 and Scope 2 Emissions) and GHG efficiency ratio, as appropriate, during the operation phase for Projects emitting over 100,000 tons of CO_2 equivalent annually. Clients will be encouraged to report publicly on Projects emitting over 25,000 tons. Public reporting requirements can be satisfied via host country regulatory requirements for reporting or environmental impact assessments, or voluntary reporting mechanisms such as the Carbon Disclosure Project, where such reporting includes emissions at Project level.

For all Projects, in all locations, when combined Scope 1 and Scope 2 Emissions are expected to be more than 100,000 tons of CO_2 equivalent annually. Consideration must be given to relevant Climate Transition Risks (as defined by the TCFD) and an alternatives analysis completed which evaluates lower Greenhouse Gas (GHG) intensive alternatives." (Equator Principles, 2020).

In summary, the principle requires the client to consider and implement technically and financially feasible measures to reduce GHG emissions during the project's design and operation. These measures may include, adopting energy-efficient technologies, utilizing renewable energy sources, optimizing resource use, and incorporating climate-resilient design. Additionally, for projects emitting more than 100,000 tons of CO_2-equivalent annually, the client must quantify and report GHG emissions annually in accordance with internationally recognized methodologies and best practices.

As part of the this methodology, both Transition Risks (such as regulatory, legal, technological, market, and workforce challenges) and Physical Risks (climate-related hazards) must be identified and evaluated to ensure comprehensive climate risk management aligned with global climate goals.

Transition Risks

Transition risks refer to potential challenges the Project may face due to the global and national shift toward a low-carbon and climate-resilient economy. These risks arise from changes in climate-related policies, technologies, market conditions, and stakeholder expectations

They can affect an organization's costs, asset values, business models, and long-term viability, particularly if the entity is slow to adapt to evolving climate requirements or public expectations.

The following Transition Risks may impact the Project:

Regulation Risks: Changes in laws, regulations or enforcement practices can impact or delay the Project. It can affect the Projects costs, operational requirements, and compliance obligations.

Technology Risk: Potential losses the Project might face due to technological changes or limitations. These might be due to adopting new technologies, falling behind in a technological way or the technological change of the current system.

Legal Risk: Potential financial, operational, or reputational impact to the Project resulting from legal actions, non-compliance with applicable laws, and changes in legal and regulatory frameworks.

Market Risk: Potential financial and operational impacts the Project might face due to changes of the market condition.

Workforce Risk: Potential challenges that the Project might face due to the availability, capacity, safety, and stability of the labor force.

Physical Risks

Physical risks refer to the potential adverse impacts of climate change on the Project due to climate-related hazards, and are determined by three key dimensions: hazard, exposure, and vulnerability. These risks can disrupt project operations, damage assets, affect health and safety, and result in financial losses if not properly assessed and managed. Understanding the interaction between these components is essential to ensure effective climate adaptation strategies.

The following aspects define the Physical Risks relevant to the Project:

Hazard: The climate-related events or trends that could potentially cause harm. This includes extreme weather events such as floods, storms, and heatwaves, as well as long-term climatic changes such as rising temperatures, sea level rise, and changing rainfall patterns.

Exposure: The presence of assets, infrastructure, people, or ecosystems in locations that could be adversely affected by climate hazards. Projects located in coastal areas, flood plains, drought-prone zones, or regions experiencing temperature extremes may face heightened exposure.

Vulnerability: The susceptibility of the Project to be adversely affected by climate hazards, based on factors such as infrastructure resilience, adaptive capacity, socioeconomic conditions, and institutional readiness. Projects with outdated infrastructure or lacking contingency plans are typically more vulnerable.

An effective climate risk assessment must evaluate these three dimensions to understand the Project's physical risk profile and to develop appropriate adaptation and resilience measures, ensuring long-term sustainability and alignment with climate-resilient development objectives.

International Requirements

There are some international agreements on combating climate change. These international agreements ensure that countries make common commitments to combat climate change. These agreements may include efforts to reduce greenhouse gas emissions, increase the use of renewable energy, and adapt to climate change. International agreements are mentioned below:

The Paris Agreement is an international climate change agreement adopted in 2015 in the capital of France, Paris, under the United Nations Framework Convention on Climate Change (UNFCCC). This agreement represents a significant step worldwide for limiting global warming and combating climate change. Türkiye ratified the Paris Agreement on October 6, 2021, after signing it on April 22, 2016. Türkiye's goals regarding the Paris Agreement are as follows:

- Reduction of Greenhouse Gas Emissions: Türkiye has committed to reducing greenhouse gas emissions by 41% by 2030. And also, Türkiye has set a net-zero emissions target for 2053
- Renewable Energy: According to Türkiye's NDC[8] (National Determined Contribution), the country aims to increase its renewable energy capacity to 90 GW by 2035. This goal includes investments in renewable energy sources such as wind, solar, hydroelectric, and biomass.
- Energy Efficiency: Türkiye aims to achieve a 16% improvement in energy efficiency by 2030 according to its NDC. This goal involves improving energy efficiency in industrial facilities, implementing energy-saving measures in buildings, and using more efficient

[8] United Nations Framework Convention on Climate Change - https://unfccc.int/sites/default/files/NDC/2023-04/T%C3%9CRK%C4%B0YE_UPDATED%201st%20NDC_EN.pdf

systems in transportation. Technical loss in energy distribution, which is currently at 12% is targeted for reduction, and energy efficiency is a key pillar of Türkiye's Climate Change Mitigation Strategy and Action Plan (2024–2030).

- Conservation of Forests: Türkiye has achieved its goal of increasing its forest cover to 30% by 2023. Türkiye will now focus on sustainable forest management, afforestation, and reforestation under the Twelfth Development Plan (2024–2028) and the Strategic Plan for Climate Change Adaptation in Forestry to boost carbon sequestration.
- Climate Change Adaptation: Türkiye's Climate Change Adaptation Strategy and Action Plan (2024–2030) focuses on building resilience across sectors like agriculture, water management, health, infrastructure, and ecosystems.

These goals represent Türkiye's commitments under the Paris Agreement and outline the country's roadmap in combating climate change. Various policies, projects, and collaborations are being implemented to achieve these objectives.

The Kyoto Protocol was adopted in Kyoto, Japan, in 1997 under the United Nations Framework Convention on Climate Change (UNFCCC). It stands as the first international agreement aimed at reducing greenhouse gas emissions. Under the Kyoto Protocol, industrialized countries and economies were expected to reduce their greenhouse gas emissions with specific targets. These targets are mostly based on emissions levels from the year 1990 and are usually expressed in percentage terms. The Protocol primarily targeted the reduction of greenhouse gases such as carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (NO_x).

The Kyoto Protocol includes flexible mechanisms like emissions trading (cap and trade), Clean Development Mechanism (CDM), and carbon credits. These mechanisms encourage trade and cooperation among countries to achieve emission reduction targets in a cost-effective manner. The Protocol targeted industrialized and emission-responsible countries, including major economies like the European Union, the United States, Japan, Canada, and Australia.

The Protocol organized emission reduction commitments into specific periods. The first period covered the years 2008-2012, while the second period covered 2013-2020. The Protocol conducts regular reviews and evaluations to monitor member countries' commitments and progress.

Türkiye signed the Kyoto Protocol but did not complete the ratification or commitment process. Therefore, Türkiye is not officially a party to the Kyoto Protocol and has not undertaken the emission reduction targets set under this protocol. Later on, Türkiye became a party to a more comprehensive climate change agreement like the Paris Agreement.

TCFD stands for Task Force on Climate-related Financial Disclosures. It is a global initiative established by the Financial Stability Board (FSB), an international organization that monitors and provides recommendations for the global financial system. TCFD aims to guide companies in providing consistent disclosures of climate-related financial risks to investors, lenders, insurers, and other stakeholders. It was launched in December 2015 as a voluntary framework. The TCFD framework aims to enhance transparency and enable investors, lenders, insurers, and other stakeholders to make more informed decisions regarding climate-related risks and opportunities. It has had a significant global impact, with many companies and financial institutions adopting TCFD recommendations in their reporting practices to demonstrate their commitment to climate-related financial disclosure and transparency.

The IPCC (Intergovernmental Panel on Climate Change) is a scientific organization established jointly by the United Nations Environment Programme (UNEP) and the World Meteorological Organization (WMO) in 1988. Its purpose is to assess and share scientific information related to climate change with policymakers.

The IPCC evaluates and synthesizes current scientific data on climate change contributed by thousands of scientists worldwide. IPCC reports include assessments of the causes, impacts, possible scenarios, and solutions related to climate change. These reports serve as guidance for policymakers and other stakeholders globally. The IPCC's scientific assessments play a significant role in shaping and implementing climate change policies for governments and international organizations. By disseminating scientific data, findings, and recommendations, the IPCC educates governments, media, academic institutions, and the public, raising awareness about climate change.

X.2.2. Baseline Conditions

X.2.2.1. Meteorological and Climatic Characteristics

In this subsection, properties of the Project area were evaluated regarding its climatic and meteorological properties.

The Project is located in the Akdeniz (Mediterranean) region of Türkiye. In Antalya, as is typical of hot-summer Mediterranean climate regions, summers are hot and dry, and winters are warm and rainy. The Taurus Mountains' lies parallel to the sea, trapping the humid air between them and the coastal area, significantly affects precipitation and temperature patterns in the province. This topographic structure, combined with climate change, contributes to the sudden and heavy rainfall observed in the city. Average summer temperatures are between 28 - 36 °C, and snow is an extremely rare occurrence in the coastlines. Heat waves affecting the region lead to anomalies, altering the typical hot and dry summer conditions by causing temperature fluctuations, and variations in rainfall patterns. These changes result in prolonged droughts and decreased precipitation, which are expected to reduce future water availability, posing serious challenges. Another anticipated effect of climate change in Antalya and its surrounding areas is the potential damage to ecosystems. Increase in droughts is predicted to pose a significant threat to endemic species of the region. Additionally, agricultural areas may also suffer, with adverse impacts on the ecological and socio-economic impacts of the climate change *(Antalya Metropolitan Municipality – Sustainable Energy and Climate Action Plan, 2022).*

The meteorological conditions of the project area were evaluated with long-term statistical data obtained from the 17954 Manavgat Meteorological Station operated by the General Directorate of Meteorology within the provincial borders.

Pressure Distribution

Annual mean local pressure measured in Manavgat Meteorology Station is 1,008.5 hPa. During the whole observation period, minimum pressure is recorded as 983 hPa in March and maximum pressure is recorded as 1,036.3 hPa in February. Monthly average, maximum and minimum pressure values recorded in the station are provided in Figure X.37 and Table X.39.

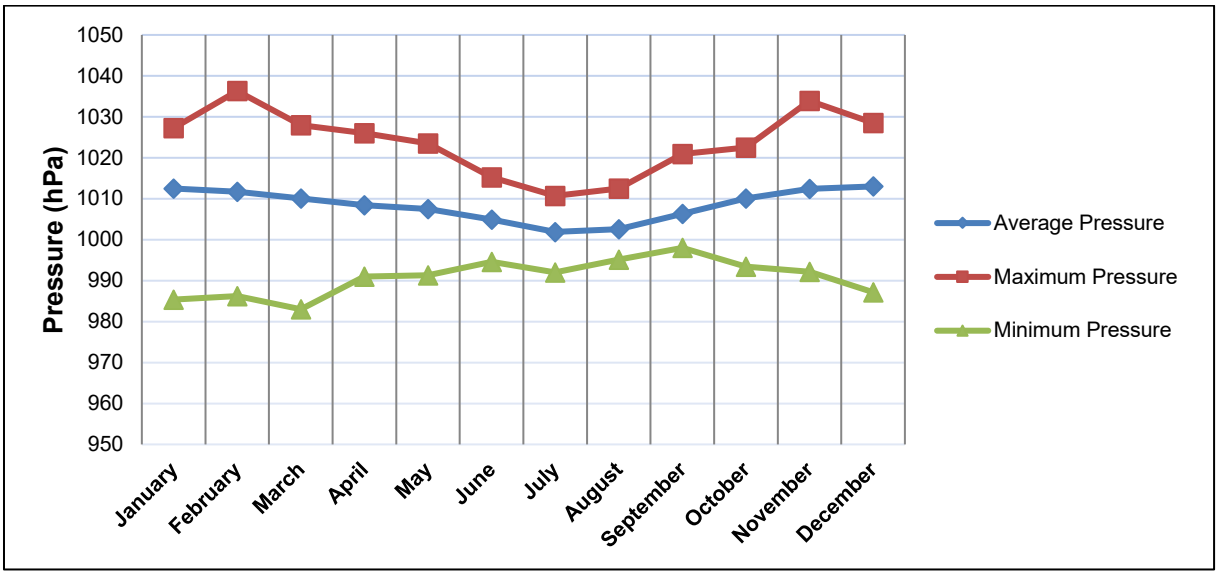


Figure X.37 Monthly Average, Maximum and Minimum Pressure Values of Manavgat Meteorology Station

Table X.39 Monthly Average, Maximum and Minimum Pressure Values of Manavgat Meteorology Station

Months	Average Pressure (hPa)	Maximum Pressure (hPa)	Minimum Pressure (hPa)
January	1,012.5	1,027.3	985.4
February	1,011.7	1,036.3	986.2
March	1,010.1	1,028	983
April	1,008.4	1,026	991
May	1,007.5	1,023.5	991.3
June	1,004.9	1,015.2	994.6
July	1,001.9	1,010.7	992
August	1,002.6	1,012.5	995.1
September	1,006.3	1,020.9	998
October	1,010.1	1,022.5	993.4
November	1,012.4	1,033.9	992.2
December	1,013	1,028.5	987.2
Annual	**1,008.5**	**1,036.3**	**983**

Temperature Distribution

According to Manavgat Meteorology Station records, annual average temperature is 18.9 °C. The highest temperature is recorded as 44.9ºC in June. The lowest temperature is recorded as –2.8ºC in February. The graphical and tabular representation of the average, maximum, minimum temperature records and maximum average and minimum average temperature records measured in this station are given in Figure X.38 and Table X.40, respectively.

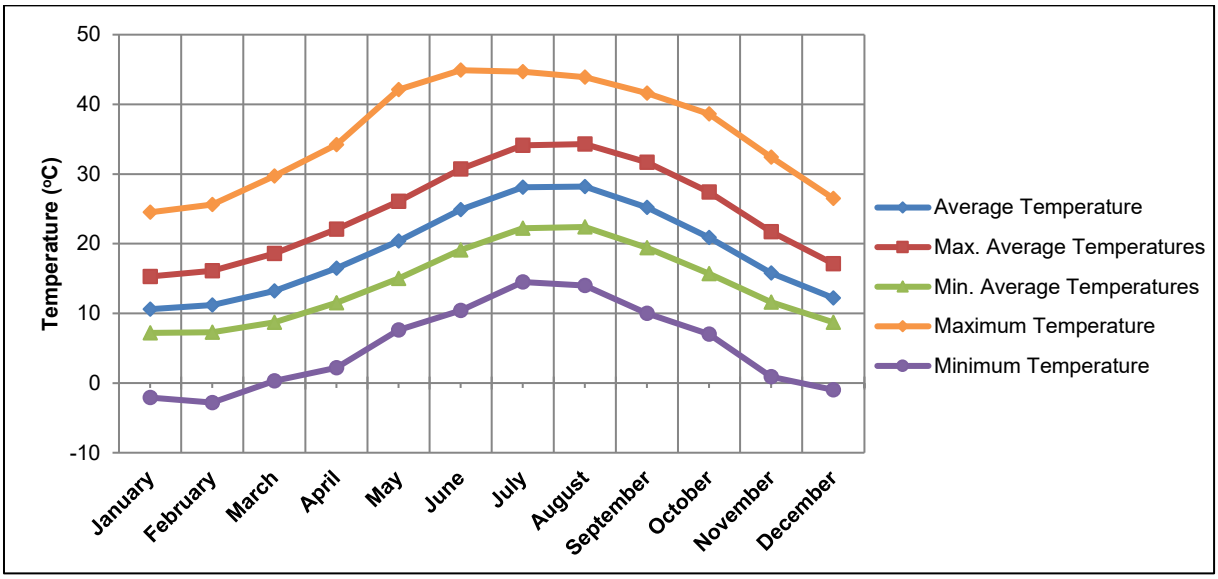

Figure X.38 Average Temperature, Maximum Average Temperature, Minimum Average Temperature of Manavgat Meteorology Station

Table X.40 Temperature Values of Manavgat Meteorology Station

Months	Average Temperature (ºC)	Max. Average Temperatures (ºC)	Min. Average Temperatures (ºC)	Maximum Temperature (°C)	Minimum Temperature (°C)
January	10.6	15.3	7.2	24.5	-2.1
February	11.2	16.1	7.3	25.6	-2.8

Precipitation Distribution

According to Manavgat Meteorology Station records, annual average total precipitation is 1,110.9 mm. Average total precipitation is maximum in December with 237.8 mm and minimum in July with 4.2 mm. During long time records, monthly maximum precipitation is recorded as 204.0 mm in January. Average monthly precipitation and daily maximum precipitation amounts are given graphically in
Figure X.39 and tabulated in Table X.41.

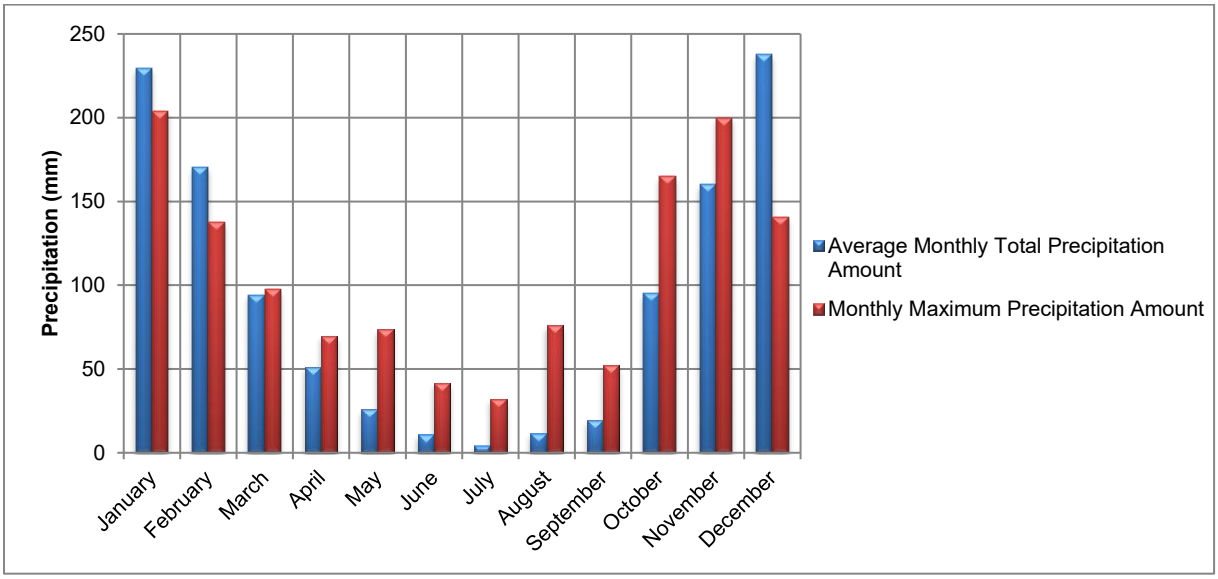

Figure X.39 Average Monthly Precipitation and Daily Maximum Precipitation of Manavgat Meteorology Station

Table X.41 Average Monthly Precipitation and Daily Maximum Precipitation of Manavgat Meteorology Station

Months	Average Monthly Total Precipitation (mm)	Monthly Maximum Precipitation (mm)
January	229.6	204.0
February	170.7	137.7
March	94.3	97.3
April	51.2	69.7
May	26.0	73.7
June	10.7	41.8
July	4.2	32.1
August	11.5	75.9
September	19.5	52.1
October	95.1	165.1
November	160.3	199.9
December	237.8	140.6
Annual	**1,110.9**	**204.0**

Humidity Distribution

According to Manavgat Meteorology Station records, average annual humidity is 63.5%. Minimum monthly relative humidity is recorded in October (59.1%) and maximum relative humidity is recorded in April (67.5%). The monthly average, minimum and maximum relative humidity values are given graphically in Figure X.40 and in tabular format in Table X.42.

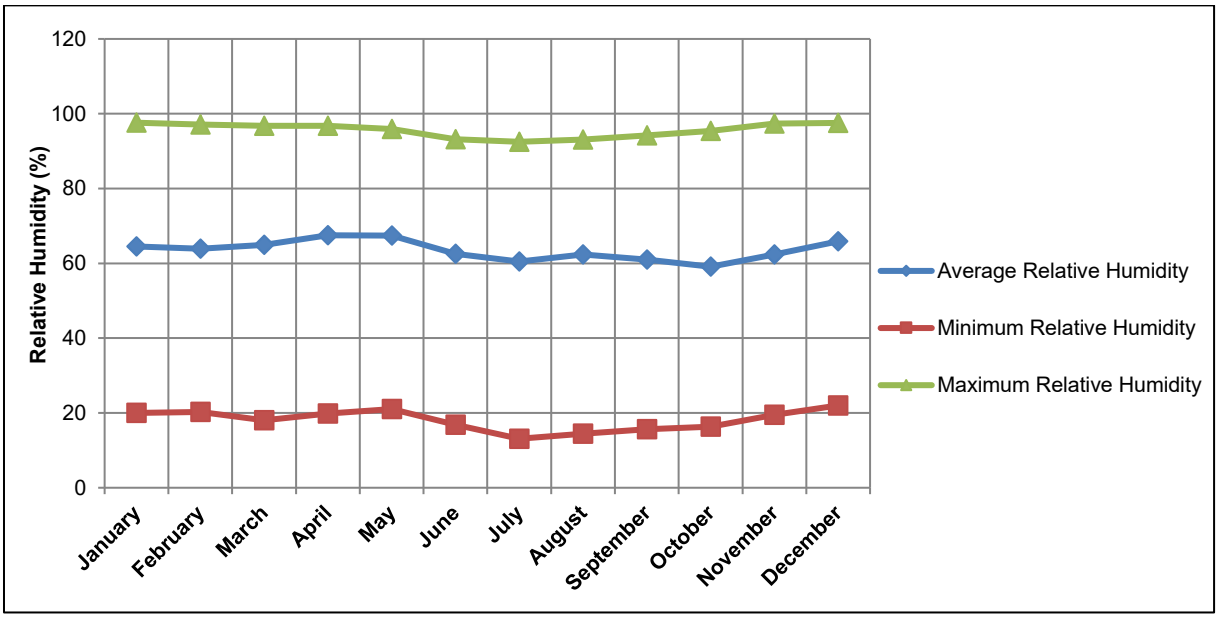

Figure X.40 Average and Minimum Relative Humidity Values of Manavgat Meteorology Station

Table X.42 Average and Minimum Relative Humidity Values of Manavgat Meteorology Station

Months	Average Relative Humidity (%)	Minimum Relative Humidity (%)	Maximum Relative Humidity (%)
January	64.5	20.0	97.6
February	63.9	20.3	97.1
March	64.9	18.0	96.8
April	67.5	19.8	96.8
May	67.4	21.0	95.9
June	62.5	16.8	93.2
July	60.5	13.1	92.5
August	62.4	14.4	93.1
September	61.0	15.6	94.2

X.2.2.2. Physical Risks of Hazards

The Project faces physical risks from natural and human-induced hazards due to the region's unique geography and bustling activity. Antalya is prone to earthquakes, flash floods, and occasional wildfires and it impacts directly the Project, which could damage infrastructure, disrupt construction, or endanger workers and future users. Identifying and addressing these hazards is crucial for ensuring the motorway's safety, durability, and minimal environmental impact, guiding effective mitigation and preparedness strategies.

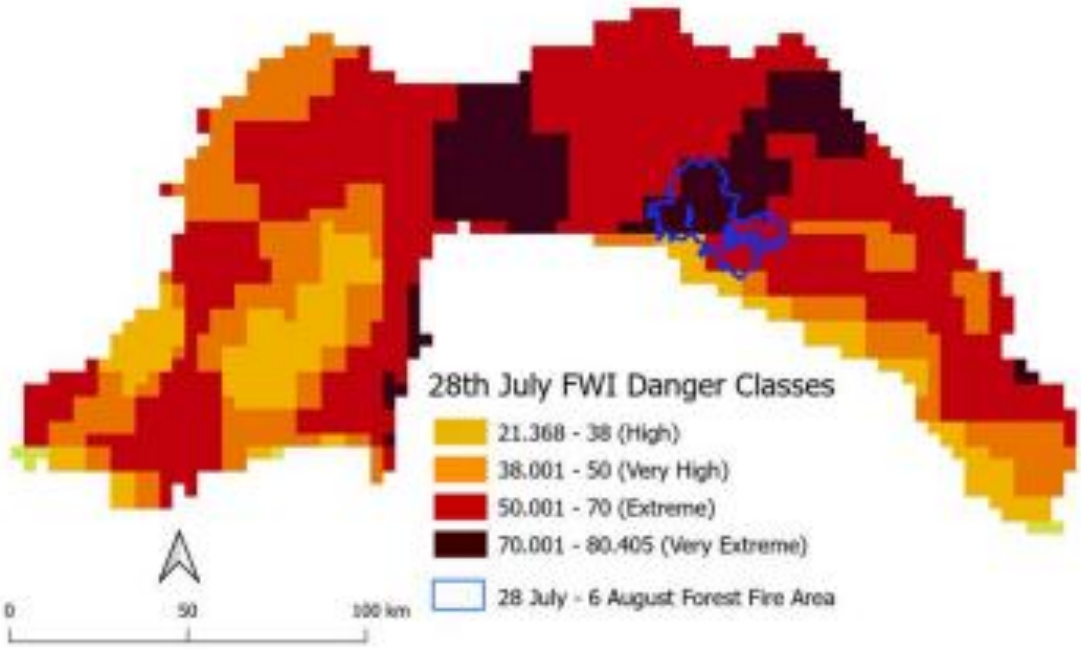
Wildfire Risk

According to the European Forest Fire Information System (EFFIS), fire danger is classified into six categories based on the Fire Weather Index (FWI), which reflects weather conditions that influence wildfire likelihood and severity. Higher FWI values indicate drier, hotter, and windier conditions, all of which increase the likelihood and intensity of wildfires. In 2021, a new category; "Very Extreme" for FWI values above 70 was introduced to better capture the severity of fire conditions observed in Mediterranean countries such as Türkiye, Greece, and Italy during intense summer wildfire events. The Fire Danger Classes and their FWI values are listed on the Table X.53.

Table X.53 FWI Value Index

Fire Danger Classes	FWI
Low	5.2 – 11.2
Moderate	11.2 - 21.3
High	21.3 - 38
Very High	38 - 50
Extreme	50 - 70
Very Extreme	>= 70

Based on the research by H. Atalay (2024)[9], Antalya is identified as a high-risk area for wildfires based on the wildfire that happened on the 28th of July 2021, with certain locations experiencing more frequent fire events. The study's findings, presented under the Creative Commons Attribution 4.0 License, were found using the EFFIS FWI map (Figure X.50) and compared with the data form 16 Meteorological stations (Figure X.51).



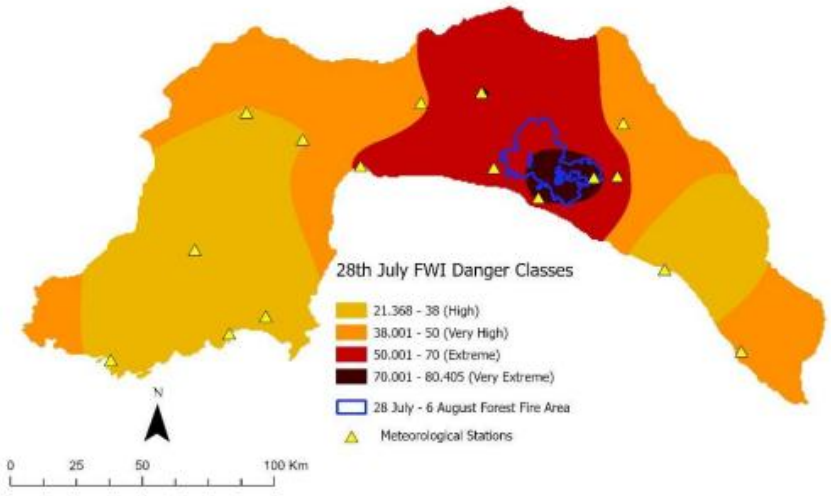
Reproduced from Atalay, H., Dervisoglu, A., & Sunar, F. (2024). **Fire Weather Index and Forest Fire Danger Mapping: Insights from a Case Study in Antalya - Manavgat Forest, Türkiye**. ISPRS Archives, XLVIII-4/W9, 53–60. https://doi.org/10.5194/isprs-archives-XLVIII-4-W9-2024-53-2024 Licensed under Creative Commons Attribution 4.0 International

Figure X.50 EFFIS FWI map (for 28 July 2021)[9]

As seen from the Figure below (Figure X.51), Antalya is a city with a high fire risk due to its climatic conditions, vegetation types, and topography. The combination of hot, dry summers and dense

[9] https://isprs-archives.copernicus.org/articles/XLVIII-M-1-2023/573/2023/isprs-archives-XLVIII-M-1-2023-573-2023.pdf

forested areas creates an environment highly susceptible to wildfires. This elevated risk underscores the importance of effective fire monitoring and prevention strategies to protect the region's natural resources and communities.



Reproduced from Atalay, H., Dervisoglu, A., & Sunar, F. (2024). **Fire Weather Index and Forest Fire Danger Mapping: Insights from a Case Study in Antalya - Manavgat Forest, Türkiye**. Figure X.51 FWI Fire Danger Map (28 July 2021)

Additionally, Antalya is an area characterized by extensive tree cover, which significantly increases the potential for wildfires to spread rapidly. Given the region's high temperatures and dry conditions, the dense forests create a perfect environment for fires to propagate quickly, exacerbating the risks to both natural ecosystems and nearby communities.

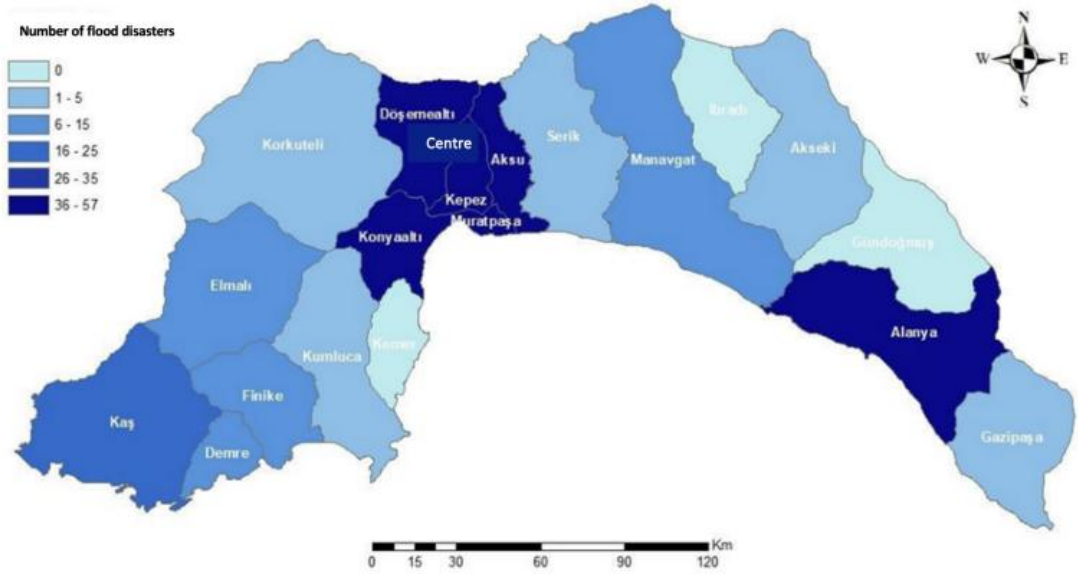
Figure X.52 ESA WorldCover LULC map of Antalya

Extreme Rainfall, Overflow and Floods Risks

According to the Municipality of Antalya, Antalya faces significant flood risks due to its Mediterranean climate, geographical structure, and urbanization, worsened by climate change. Increased sea and ocean temperatures drive higher evaporation, leading to moisture-laden air masses that cause sudden, heavy rainfall. This results in flooding and inundation, particularly in urban areas with inadequate infrastructure and impermeable surfaces that prevent water infiltration, causing rapid runoff to low-lying areas (Figure X.53).



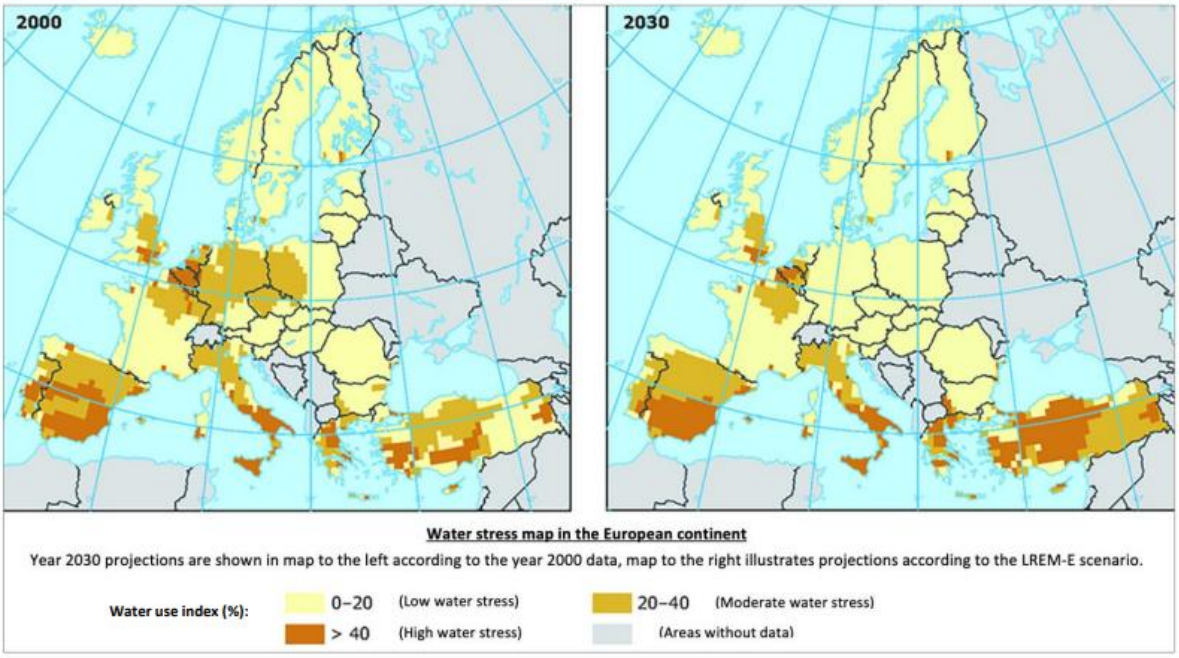
Source: AFAD, İRAP, 2021 (MGM data).

Figure X.53 Distribution of flood disasters in Antalya between 1975 and 2020

In the years 1993, 1995, 1999, 2001, 2002, 2003, 2009, 2010, and 2013 in Antalya major floods happened, with a notable flood in Elmalı (2018) causing loss of life and property damages. The 2021 AFAD IRAP report notes that between 1975 and 2020, central districts like Döşemealtı, Kepez, Muratpaşa, Aksu, and Konyaaltı, followed by Kumluca, Finike, Manavgat, Kemer, Demre, and Alanya, recorded the highest number of flood disasters. With 80% of Antalya's 1085 mm annual rainfall (1100 mm in Manavgat and Alanya) occurring in winter meaning that the flash flood risks are high. Vulnerable sectors include agriculture, tourism, infrastructure, and health, with at-risk groups such as women, children, seniors, low-income communities, and those in substandard housing risks.

Water Scarcity and Drought Risk

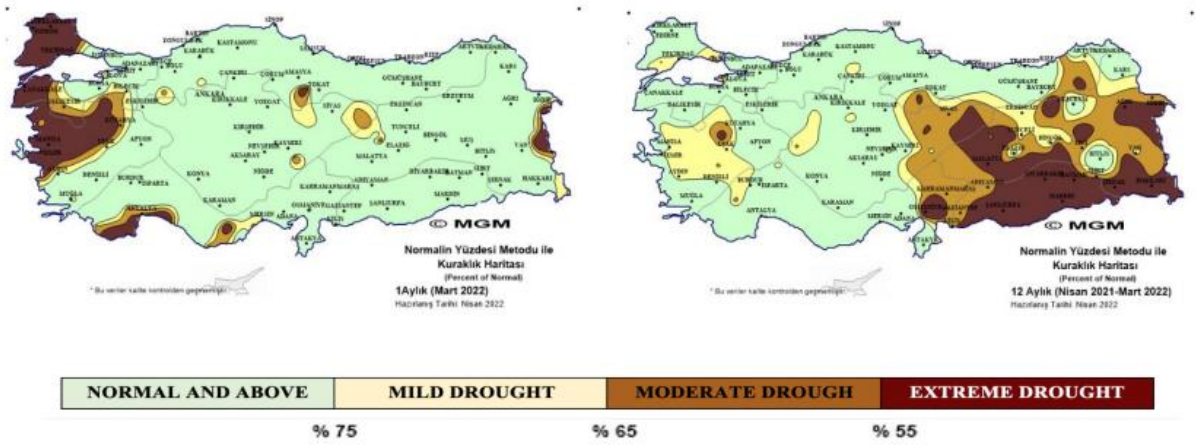
According to the European Environment Agency (EEA) and related scientific sources, water scarcity is assessed using the Water Exploitation Index (WEI), which measures the ratio of average long-term freshwater demand to available water resources. Higher WEI values indicate greater pressure on water resources, highlighting regions with high water demand or limited supply (Figure X.54).



Source: SECAP (Sustainable Energy and Climate Action Plan) 2022 – Antalya Metropolitan Municipality

Figure X.54 European river basins in 2000 and a forecast scenario for 2030

In Antalya, long-term declines in precipitation (notably from 1960 to 2015) and rising demand from population growth and agriculture have increased the risk of water scarcity. Droughts in 1973–1974 and 1989–1991 were particularly severe. Although long-term studies, as shown in the Figure X.55, suggest no consistent drought trend, they do indicate variability over time, while short-term analyses reveal moderate drought conditions that fluctuate from year to year.



Source: SECAP (Sustainable Energy and Climate Action Plan) 2022 – Antalya Metropolitan Municipality[10]

Figure X.55 Türkiye drought map for March 2022 on left and April 2021-March 2022 on the right

Despite forested areas and river systems, Antalya is highly vulnerable due to intensive greenhouse agriculture, groundwater overuse, and climate-driven rainfall decline. Drought management plans were introduced in 2018, but ongoing high water use and insufficient recharge continue to threaten ecosystems and water security.

Heatwaves Risks

According to data and studies[11], heatwaves are periods of unusually high surface temperatures lasting days or week. In Antalya, average temperatures have been rising since the 1980s, particularly in summer when they often exceed 40°C. Heat stress occurs when the body is unable to regulate its temperature effectively due to high ambient heat (Table X.54). It can lead to symptoms such as fatigue, dizziness, muscle cramps, and in severe cases, heat stroke. Prevention includes adequate hydration, rest, and appropriate clothing.

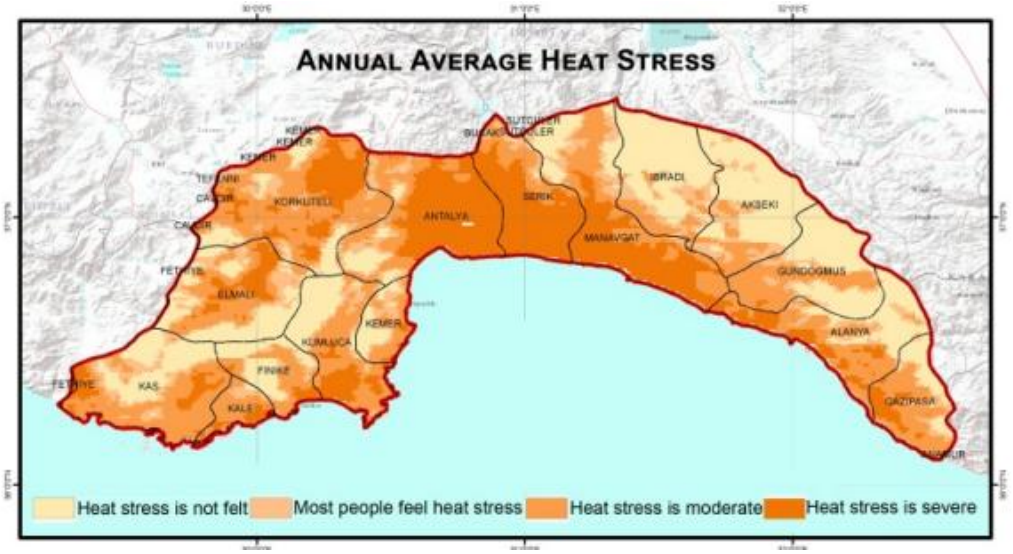
Table X.54 Heat Stress Index

Discomfort Index (DI)	Heat Stress	Description
<22	Heat stress is not felt	A mild heat can be sensed by most people
22 - 24	Most people feel heat stress	Heat stress is moderate
24 - 28	Heat stress is moderate	People feel very hot within this range and difficulties may be found when physical work is performed
>28	Heat stress is severe	People who perform physical work are at high risk of heat-associated illness, such as heat exhaustion and heat stroke

[10] https://www.antalya.bel.tr/Content/UserFiles/Files/YarinlardaBizVariz/Dokumanlar/2022/2022-Y%C4%B1l%C4%B1-SECAP.pdf

[11] https://isprs-archives.copernicus.org/articles/XLVIII-M-1-2023/573/2023/isprs-archives-XLVIII-M-1-2023-573-2023.pdf

Antalya experiences hot summers with temperatures often exceeding 35°C. These conditions increase the risk of heat stress, especially for outdoor workers and vulnerable populations. High humidity levels can worsen the body's ability to cool itself, leading to symptoms such as fatigue, dizziness, and heat-related illnesses. Effective measures such as hydration, shade, and work-rest cycles are essential to mitigate heat stress in this region (Figure X.56).

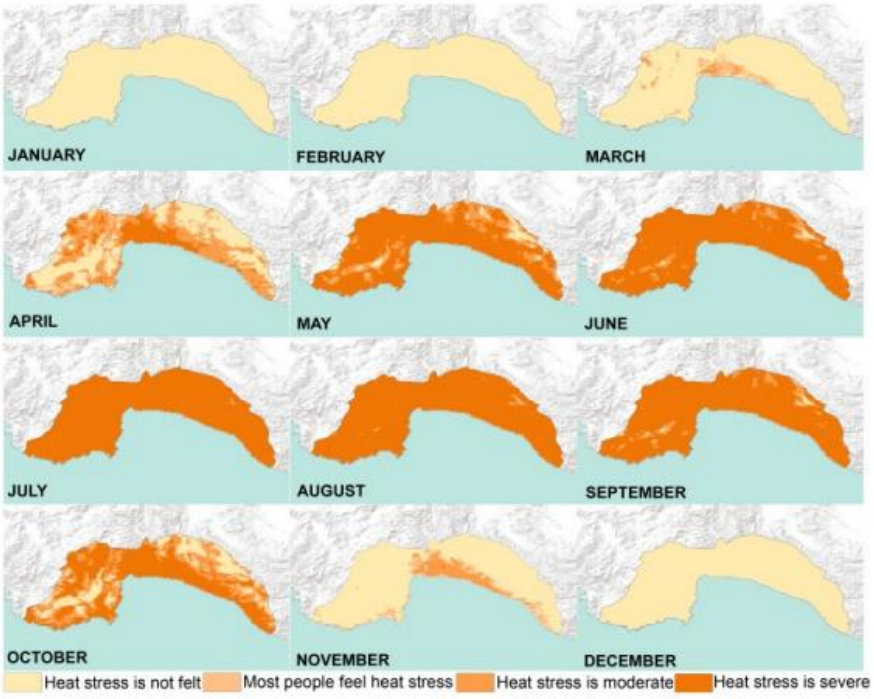


Adapted from Şahingöz, M. and Berberoğlu, S.: DETECTION OF DISCOMFORT INDEX WITH REMOTE SENSING TECHNOLOGY: THE CASE OF ANTALYA PROVINCE, Int. Arch. Photogramm. Remote Sens. Spatial Inf. Sci., XLVIII-M-1-2023, 573–578, https://doi.org/10.5194/isprs-archives-XLVIII-M-1-2023-573-2023 , 2023.

Figure X.56 Annual average heat stress in Antalya

Heat waves also disrupt agriculture in the region. Higher temperatures and more frequent hot days damage crops, increase pests, and reduce yields. While warmer weather extends growing seasons in inland areas like Elmalı and Korkuteli, allowing for more crops or variety, it also intensifies evaporation and drought, straining water resources. Heavy irrigation further threatens lakes in the region with depletion.

Antalya's tourism sector, which is vital to the coastal economy, faces challenges from rising summer temperatures, which increase energy demands, cause water shortages, and raise risks of infectious diseases and poor air quality. As shown on the Figure X.57, the Heat Stress is severe for 7 months straight which can be attractive to tourists because of the warmer weather.



Adapted from Şahingöz, M. and Berberoğlu, S.: DETECTION OF DISCOMFORT INDEX WITH REMOTE SENSING TECHNOLOGY: THE CASE OF ANTALYA PROVINCE, Int. Arch. Photogramm. Remote Sens. Spatial Inf. Sci., XLVIII-M-1-2023, 573–578, https://doi.org/10.5194/isprs-archives-XLVIII-M-1-2023-573-2023 , 2023.

Figure X.57 Monthly distribution of discomfort index

The urban heat island effect worsens these issues in Antalya. Rapid urbanization has reduced green spaces and agricultural areas, replacing them with heat-trapping concrete, making the city feel hotter. Temperature data from 1980 to 2019 shows a clear warming trend, with most months in the last decade being warmer than earlier periods. Projections indicate Antalya will face even higher temperatures and drought in the future, amplifying these challenges.

Storms, Strong Winds and Tornados Risks

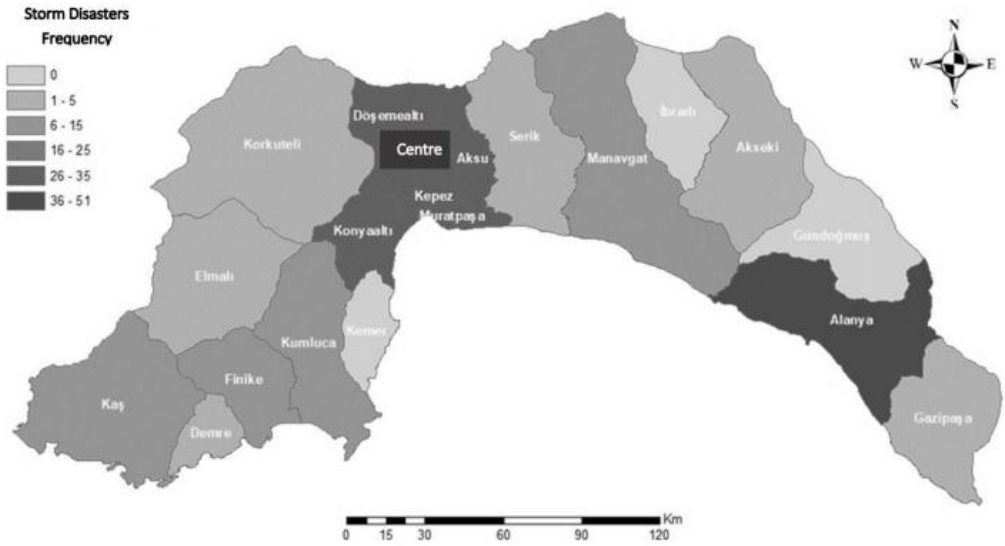
Storms, characterized by severe atmospheric phenomena such as cloud cover, precipitation, strong winds, lightning, or thunder, are expected to increase in frequency and intensity due to climate change.Antalya, due to its geographical structure, topography, land-sea interaction, and climatic characteristics, experiences frequent tornado and storm events. The 2021 IRAP report by AFAD notes that these events are difficult to predict precisely, as they occur rapidly under specific atmospheric conditions and can only be detected through remote sensing and short-term forecasts. This unpredictability underscores the need for adaptive infrastructure in the city

Acording to the Antalya Municipality[10], Greenhouse and agricultural activities, which are common in Antalya, are highly vulnerable to tornadoes and storms, resulting in significant damage to crops, equipment, and sometimes the loss of life. Between 2000 and 2020, AFAD data indicates that Alanya, central districts, Finike, and Kaş experienced the highest number of tornado events (Table X.55) with a recorded wind speed of 155 km/h in Antalya's city center during that period, far exceeding the 60 km/h threshold for a meteorological storm.

Table X.55 Number of Tornado Disasters in Antalya between 1975 and 2020

District	Number of Tornado Disasters
Alanya	51
Merkez	36
Finike	27
Kumluca	27
Kaş	17
Demre	6
Manavgat	6
Gazipaşa	3
Korkuteli	1
Akseki	0
Elmalı	0
Gündoğmuş	0
İbradı	0
Kemer	0
Serik	0

In March 2022, severe tornadoes, storms, and downpours struck Aksu, Serik, Gazipaşa, and Alanya districts at night, causing extensive damage to greenhouses and crops. In Serik, 256 decares of greenhouse area belonging to 65 farmers suffered 80% damage. In Alanya, 230 decares of agricultural land owned by 55 farmers were affected. Gazipaşa saw 10 decares of greenhouses damaged for 3 farmers, while in Aksu, 134 decares of greenhouse area and 18 decares of olive orchards were impacted. Overall, 630 decares of greenhouse areas were damaged, affecting hundreds of farmers.



Source: SECAP (Sustainable Energy and Climate Action Plan) 2022 – Antalya Metropolitan Municaplity

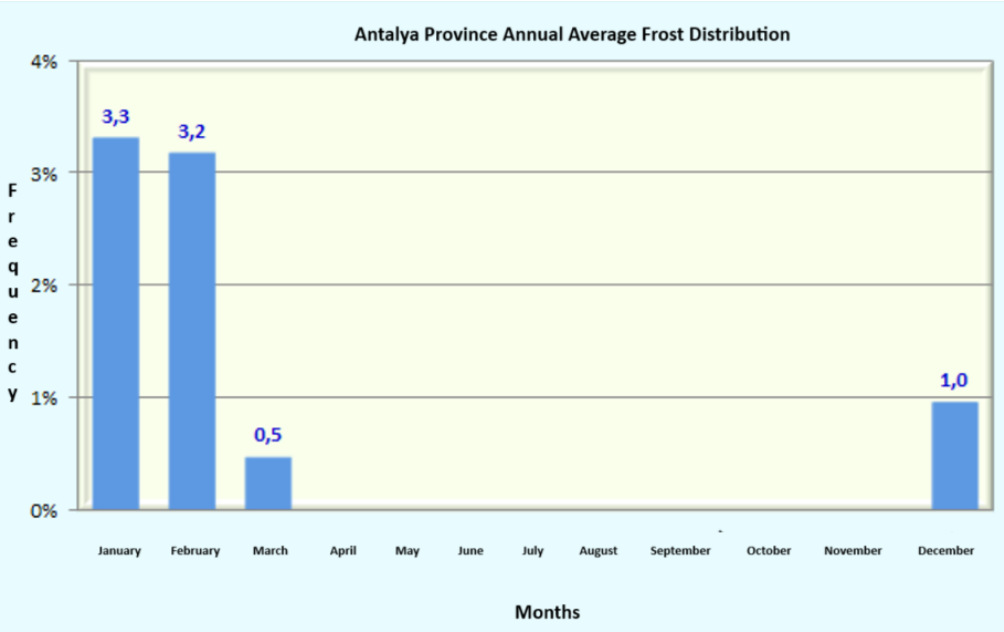
Figure X.58 Distribution of storm disasters in Antalya between 1975 and 2020

The high prevalence of greenhouse and agricultural activities in Antalya amplifies the damage from these weather events. With climate change driving more frequent and severe atmospheric changes, the risk of tornadoes and storms in Antalya is high in the present and also in the future. Research findings confirm this elevated risk, particularly noting frequent tornadoes in Finike, Demre, and Kemer districts.

Cold Waves and Snowfall

A cold wave, also known as a cold snap or deep freeze, is a weather event marked by a sharp and rapid temperature drop across a large area, resulting in temperatures significantly below the region's seasonal norms. Cold waves can cause widespread issues, including risks to human health, damage to crops and property, and disruptions to essential services. Often linked with severe winter weather like blizzards or ice storms, these events may bring snowfall, creating hazardous travel conditions, accumulating on infrastructure, and straining public services. Strong winds can worsen the impact by increasing wind chill, making temperatures feel even colder.

According to the General Directorate of Meteorology, frost hazards in Antalya occur predominantly during the winter months, typically between December and February (Figure X.59).



[12]Source: General Directorate of Meteorology of Türkiye

Figure X.59 Antalya Province Annual Avarage Frost Distribution

According to the Municipality of Antalya, cold waves have negatively affected greenhouse activities, with frost risks being notably higher in Aksu and Serik. Additionally, in Elmalı, Korkuteli, Akseki, and İbradı, frost events that previously occurred in late April have shifted to May since 2022.

,

X.2.3. Potential Impacts

X.2.3.1. Land Preparation and Construction Phase

Potential impacts of the project on climate change would occur through greenhouse gas emissions generated during the construction phase. Greenhouse gas emissions from the project are estimated in terms of CO_2 equivalent (CO_2 e), representing all greenhouse gas emissions in CO_2 form.

During the construction phase of the Antalya- Alanya Motorway Project, from Serik to Alanya, GHGs will be generated due to consumption associated with operation of construction machinery, equipment, and vehicles, operations in quarries and material transportation, personal shuttles, heating and energy needs of the personnel for the creation of the motorway (84 km of the main Route) and access roads (33.8 km of the Route). The major greenhouse gas emission will be CO_2 emissions resulting from the combustion of petroleum-based products such as diesel engines of construction vehicles and electric generators. Relatively small amounts of methane and nitrous oxide will also be emitted during fuel combustion.

Scope 1 Greenhouse Gas Emissions from Direct Fuel Combustion for the construction phase

The number of equipment to be used during the construction phase of the Project, which is expected to last approximately 36 months (3 years), is provided in Chapter III.6. These equipment are estimated to consume approximately 83,295,537 liters of diesel-based fuel and 13,176.34 tons of LNG. The

[12]https://mgm.gov.tr/FILES/ziraat/TrDonHaritasi/antalya.png

estimated GHG emissions in total and per year (in tCO_2 e and tCO_2 e/year) which will be determined by the expected fuel usage during this stage are presented on Table X.56.

Table X.56 GHG Emission from Fuels for Construction Phase (Scope 1)

Fuel (Unit)	Consumption (Total) [liter]	Consumption (Total) [ton]	Conversion Factor [kg CO_2e]*	Emissions (Total) [tCO_2 e]	Emissions (Annual Average) [tCO_2 e/year]
Diesel	83,295,537	-	2.66	221,566.13	73,855.38
LNG	-	13,176.34	2,590.46	34,132.84	11,377.59

*https://www.gov.uk/government/publications/greenhouse-gas-reporting-conversion-factors-2024

The total GHG emission of fuel sources during the construction will be 255,697 tCO_2 e. The estimated greenhouse gas emissions is 85,232.91. tCO_2 e per year

Scope 2 Greenhouse Gas Emissions from Electricity Consumption for the construction phase

During the 36-month construction period, electricity will be sourced from the public grid to support both infrastructure operations and workforce accommodations. Infrastructure use including site offices, lighting, and equipment is estimated to consume 49,622,017 kWh. In parallel, electricity use by approximately 3,300 workers across three labor camps, for daily living such as lighting, air conditioning, and appliances, is projected at 35,175,535 kWh. In the calculation of greenhouse gas emissions resulting from electricity generation and consumption, conversion factor published in Türkiye Electricity Production And Electricity Consumption Point Emission Factors Information Form data from the year 2022 were used as the basis. The electricity generation emission factor for Türkiye in 2022 was determined to be 0.438 $kgCO_2e/kWh$. (see Table X.57).

Table X.57 Emissions from Electricity Use During Construction Phase (Scope 2)

Energy (Unit)	Consumption (Total) [kWh]	Consumption [kWh/year]	Emission Factor [kg CO_2 e/kWh]*	Emissions (Annual Average) [tCO_2 e/year]
Electricity (Infrastructure)	49,622,017	16,540,672.33	0.438	7,244.81
Electricity (People)	35,175,535	11,725,178.44	0.438	5,135.63

*https://enerji.gov.tr/evced-cevre-ve-iklim-elektrik-uretim-tuketim-emisyon-faktorleri

The total GHG emission from electricity sources during the 3 years of the construction phase will be 37,141.32 tCO_2 e. The estimated greenhouse gas emissions is 12,380.44 tCO_2 e per year

Equator Principle IV (2020) requires clients to publicly disclose annual greenhouse gas emissions if the combined Scope 1 and Scope 2 emissions during the construction phase exceed 100,000 tons of CO_2 equivalent. The Project is estimated to generate a total of 97,613.35 tons of CO_2 equivalent per year from Scope 1 and Scope 2 emissions, which is below the Equator Principles' threshold of 100,000 tCO_2 e per year, which would otherwise trigger a detailed climate change risk assessment and mitigation plan. This indicates the Project's compliance with relevant Equator Principles requirements.

To continue, the Project has identified and committed to implementing feasible emission reduction measures, in alignment with IFC Performance Standard 3 (PS3) and the Equator Principles.

Overall, the Project adheres to both regulatory and voluntary standards for greenhouse gas management for the construction phase, demonstrating a strong commitment to responsible environmental stewardship in accordance with national and international climate frameworks.

X.2.3.2. Operation Phase

During the operation phase of the Antalya-Alanya Project (Serik to Alanya motorway), greenhouse gas (GHG) emissions will primarily result from the ongoing activities associated with the, maintenance of the motorway, and its access roads and the electricity to use for the motorways infrastructure. Below is an overview of the potential GHG emissions during this phase, focusing on carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O), which are generated due to vehicle traffic, maintenance activities, and related infrastructure operations.

Scope 1 Greenhouse Gas Emissions from Direct Fuel Combustion for the operation phase

During the 12-year operation phase, GHG emissions will arise from the combustion of LNG for cooking and heating systems, daily travel by 50 company vehicles (25 electric and 25 petrol, each covering 100 km/day) shown on Table X.58, and operation of 3 heavy-duty diesel based vehicles daily, running 10 hours for maintenance activities shown on Table X.59.

Table X.58 GHG Emission from Maintenance vehicles Fuels for the Operation Phase (Scope 1)

Vehicle Type	Number of vehicles	Working hours per day	Days	Liters consumed per hour (l / h)	Conversion Factor [kg CO2e]	Total CO_2 Emissions (t CO_2eq/year)*
Heavy Maintenance Vehicle	3	10	365	30	2.66	873.81

Table X.59 GHG Emission from Car Fuels for the Operation Phase (Scope 1)

Car Type	Number of vehicles	Distance travelled per day (km)	Days	Conversion Factor [kg CO2e]	Total CO_2 Emissions (t CO_2eq/year)*
EV	25	100	365	0.07015	64.01
Petrol	25	100	365	0.1645	150.11

For the LNG usage:

- Energy demand to Cook for 250 employees:
    - For 250 employees, The usage of 5 GJ/day for cooking appliances such as stoves and ovens.

- LNG equivalent will be 5 / 50 GJ/ton = 0,1 tons/day (lower heating value (LHV) of methane is 50 GJ/ton).
- 365*0,1 =36.5 tons/year of LNG
- With the conversion rate of 2,590.46 kg CO_2e, we find 94.55 t CO2 e/ year of LNG use for cooking

- Heating
  - 1000m^2 of areas that needs to be heated, As Antalya has generally a warmer climate we will take 0.2GJ/m2 a year to heat
  - 0.2*1000=200 GJ/ year
  - And the LNG equivqalent is 50 GJ/t so 200/50 = 4 tons/year
  - With the conversion rate of 2,590.46 kg CO_2e, we find 10.36 tCO2 e/year

The total GHG emission of fuel sources during the operation phase will be 14,314.08 tCO_2 e during a period of 12 years. The estimated greenhouse gas emissions is 1,192.84 tCO_2 e per year, which is below the Equator Principles' threshold of 100,000 tCO_2 e per year and 25,000 tCO_2 e per year.

Scope 2 Greenhouse Gas Emissions from Electricity Consumption for the operation phase

During the operation phase, the primary power source for the motorway infrastructure will be the public electricity grid. Electricity consumption will be limited to essential operational systems such as roadway lighting, traffic management systems, electric signage, and EV charging stations. As the total value of the consumption of electricity is not known, the worst-case scenario approach has been applied to estimate annual electricity consumption. The electricity consumption values for the operation phase were obtained from the Project Sponsor and were based on the annual total electricity consumption data from 2024 for a completed motorway project of similar nature. This estimate also incorporates the power consumption of electric vehicle charging units and other project-specific technical details. In the calculation of greenhouse gas emissions resulting from electricity generation and consumption, conversion factor published in Türkiye Electricity Production And Electricity Consumption Point Emission Factors Information Form data from the year 2022 were used as the basis. The electricity generation emission factor for Türkiye in 2022 was determined to be 0.438 kg CO_2 e/kWh. (Table X.60).

Table X.60 Emissions from Electricity Use During the Operation Phase (Scope 2)

Energy (Unit)	Consumption [kWh/year]	Emission Factor [kg CO_2 e/kWh]	Emissions (Annual Average) [tCO_2 e/year]
Electricity (Infrastructure)	21,267,933	0.438	9,315.35

The total GHG emission from electricity sources during the 12 years of the operation phase will be 111,784.2 tCO_2 e. The estimated greenhouse gas emissions is 9,315.35 tCO_2 e per year

Equator Principle IV (2020) also requires clients to publicly disclose annual greenhouse gas emissions if the combined Scope 1 and Scope 2 emissions during the construction phase exceed 100,000 tons of CO_2 equivalent and encourages the public disclosure if it exceeds 25,000 tons of CO_2 equivalent. The Project is estimated to generate a total of 10,508.19 tons of CO_2 equivalent per year from Scope

1 and Scope 2 emissions, which is below the Equator Principles' threshold of 100,000 tCO_2 e per year, which would otherwise trigger a detailed climate change risk assessment and mitigation plan or the threshold of 25,000 which encourages the public disclosure. This indicates the Project's compliance with relevant Equator Principles requirements.

Overall, the Project adheres to both regulatory and voluntary standards for greenhouse gas management for the operation phase, demonstrating a strong commitment to responsible environmental stewardship in accordance with national and international climate frameworks.

Carbon Capture Capacity

Carbon is retained in biomass, decomposing organic matter and soil in terrestrial ecological systems. Carbon stock in terrestrial ecological systems plays an important role in the global carbon cycle. Carbon is exchlanged between ecological systems and the atmosphere through natural processes such as photosynthesis, respiration, decomposition and combustion. Human activities change the carbon stocks in ecological systems and alter the exchanges between the carbon pools and the atmosphere through land use and land use change (*IPCC, 2000)*.

Antalya-Alanya Motorway Project is considered to have a potential impact on regional carbon stocks through removal of forests for motorway construction. In this section, the losses in carbon capture and oxygen generation capacities due to deforestation activities are estimated. Loss of carbon capture capacity is based on a comparative analysis of this capacity with regard to the official data held by the District and Sub-District Directorates of Forestry regarding the capacity that has been calculated to exist in the region of responsibility of each directorate. The region of responsibility is the geographical area/region where the directorate is responsible for managing all the forest areas and assets in this region (including provision of permits in the forest areas, reforestation/afforestation activities, tree planting and removing). As a result of this evaluation, the significance assessment has been made based on the calculated availability of carbon capture capacity and the forest area to be lost.

Number of trees to be removed and the area they occupy are determined and calculated from forestry inventory data in forest management plans of the relevant directorates (Serik Forestry Management Directorate, Taşağıl Forestry Management Directorate, Manavgat Forestry Management Directorate, and Alanya Forestry Management Directorate) under Antalya Regional Directorate of Forestry and summarized in Table X.61.There are a total of 10 forestry sub-districts namely; Akbaş, Alara, Kargı, Çardak, Taşağıl, Manavgat, Naras, Selale, Yalçıdibi, and Murtiçi.

Table X.61 Number of Trees to be Removed, Area Occupied and Total Forest Area

Number of Trees Removed	Area Occupied by Trees Removed (ha)	Total Forest Area Under Responsibility of the Directorates (ha)
278,915	1,030.69	166,817.30

Loss in the amount of carbon capture capacity and oxygen generation capacity is estimated from the data provided in the forest management plans and the amount of forest area to be lost in scope of the project and presented in Table X.62.

Table X.62 Loss of Carbon Capture Capacity and Oxygen Generation Capacity

Carbon Capture Capacity		
Total Carbon Capture Capacity of the Forest Area	tons	1.056.769
Loss of Carbon Capture Capacity	tons	3.542
Loss of Carbon Capture Capacity	%	0.34
Oxygen Generation Capacity		
Total Oxygen Generation Capacity of the Forest Area	tons	45.807
Loss of Oxygen Generation Capacity	tons	154
Loss of Oxygen Generation Capacity	%	0.34

Carbon Capture Capacity		
Total Carbon Capture Capacity of the Forest Area	Tons	8,478,683
Loss of Carbon Capture Capacity	tons	52,386
Loss of Carbon Capture Capacity	%	0.62
Oxygen Generation Capacity		
Total Oxygen Generation Capacity of the Forest Area	tons	147,096
Loss of Oxygen Generation Capacity	tons	909
Loss of Oxygen Generation Capacity	%	0.62

As it can be seen in Table X.62, the removal of forests corresponds in a 0.62% reduction in the total carbon capture and oxygen generation capacity within the area of authorization of 10 sub-districts managements of Antalya Forestry. This loss reflects the impact of deforestation activities carried out within the project area and is quantified based on the estimated biomass and carbon storage of the affected forestland.

Infrastructure Effects on Climate Change

Throughout the project lifecycle, the motorway will contribute to climate change through both direct and indirect pathways. As shown previously, multiple phases of the project, including deforestation, construction, operation, and traffic, plays a role in greenhouse gas (GHG) emissions and impacting the climate. The direct and indirect effects of the Project infrastructure will be shown below:

- Deforestation: Removal of trees that will absorb CO_2 and will reduce the land's ability to capture greenhouse gases.
- Construction phase of the project:
  - Constructions emissions: Concrete and asphalt will add significant CO_2 to the atmosphere due to their energy-intensive production.
  - Fuel use: Generates direct GHG emissions
  - Material transportation: Emissions though to fuel and energy use.
- Operation phase of the project:

- Electricity use: EV charging docks, and traffic and lighting controls will contribute to emissions.
- Traffic: While the motorway is expected to serve millions of users annually, a substantial portion of this traffic will be diverted from the existing D400 highway. Therefore, the project primarily reallocates existing traffic rather than generating entirely new vehicle flows. Although some induced traffic may occur over time due to improved connectivity, its overall contribution to emissions is expected to be incremental relative to the diverted baseline.
- Urban sprawl: The motorway may contribute to increased regional accessibility, which could in turn support population growth and land development. However, such trends are influenced by multiple external factors, and the emissions impact attributable specifically to the motorway is expected to be limited compared to broader socioeconomic drivers.

The motorway is expected to contribute to greenhouse gas emissions through deforestation, construction, and long-term operation. With thoughtful planning and mitigation, these impacts will be managed to support more sustainable outcomes.

Transition Risks

For the Project, the transition risks will be associated with changes in regulatory frameworks, market dynamics, and stakeholder expectations. These risks may impact project timelines, cost structures, and compliance obligations, requiring proactive management and flexible adaptation strategies.

Table X.63 Transition Risks, their Impacts and Mitigations

Transition Risk	Description	Potential Impact	Mitigation Measures	Responsible Party	Monitoring KPIs
Policy and Legal Risks	New carbon pricing or emissions regulations in Türkiye	Increased operational costs or compliance fines.	Integrate low-carbon design (e.g., energy-efficient lighting); monitor policy changes.	SPV	Annual policy review; compliance audit results.
Technology Risks	Shift to EV or smart transport technologies.	Reduced demand if infrastructure is outdated.	Install EV charging stations; design for future smart traffic systems.	SPV and EPC	Number of EV stations installed; technology upgrade plan.
Market Risks	Declining private vehicle use due to low-carbon transport preferences.	Lower toll revenues.	Promote multi-modal transport links (e.g., smart lanes); and market to eco-conscious users.	SPV	Traffic volume trends; revenue forecasts.
Reputational Risks	Community or NGO opposition to environmental impact.	Project delays or loss of stakeholder support.	Engage communities early; implement transparent emissions reporting.	SPV	Number of consultations; public sentiment analysis.

Transition risks must be taken into consideration during the whole Project. By adopting low-carbon technologies, the project can remain resilient and aligned with evolving market, policy trends, and regulations for a greener Türkiye.

Impact of Climate Change on the Project

Changes in the air temperature and precipitation regimes in the future years are expected due to the impacts of the climate change. In order to analyze mentioned and other impacts of the climate change, modeling studies are carried out by generating various scenarios. These scenarios are defined as a specific pathway or storyline within the Shared Socioeconomic Pathways (SSPs) framework. The SSPs are developed by the Intergovernmental Panel on Climate Change (IPCC) to explore different possible futures based on varying combinations of socioeconomic development and climate policies. Based on the evaluations on these scenarios, two of these scenarios were chosen to assess the climate change vulnerability of the Project. Two extreme SSP5-8.5 (Fossil Fuel Development Pathway) and SSP1-2.6 (Sustainability Pathway) scenarios were selected for the modeling study.

SSP1-2.6 (Sustainability Pathway):

The SSP1-2.6 scenario, often referred to as the "Sustainability Pathway," envisions a future where strong efforts are made to achieve sustainable development goals and mitigate climate change. This scenario assumes a high level of international cooperation, rapid technological advancement, and ambitious climate policies aimed at limiting global warming to well below 2 degrees Celsius above pre-industrial levels by the end of the century.

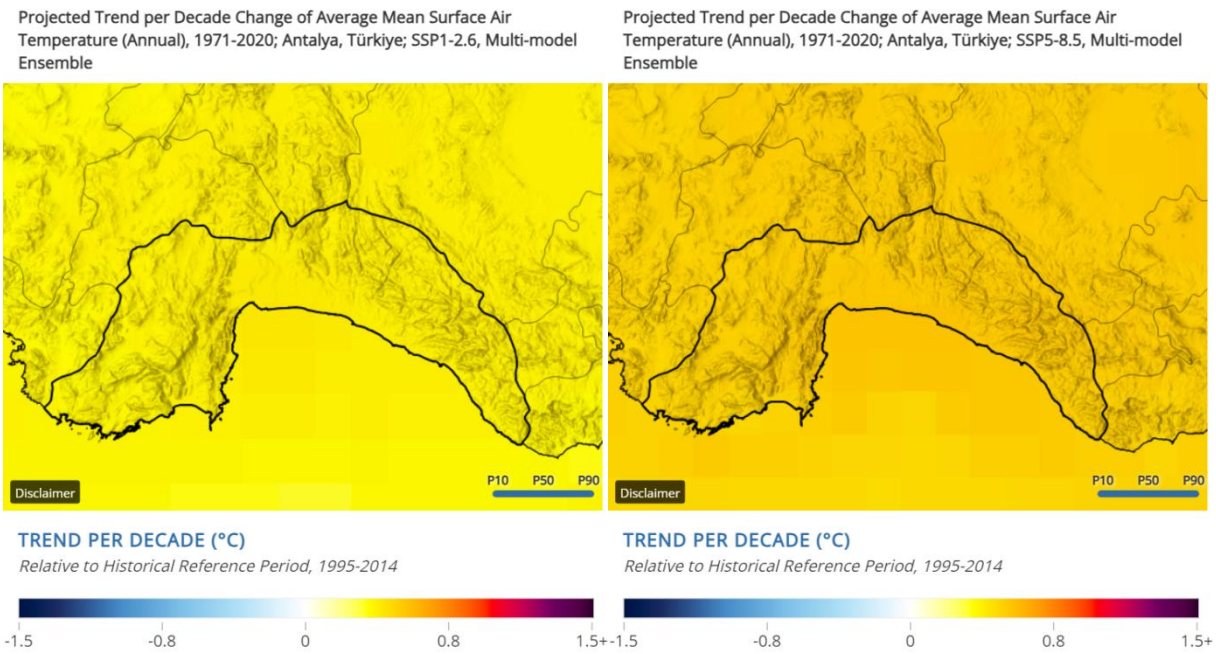
The SSP1-2.6 Scenario features robust economic growth coupled with equitable distribution of resources and wealth. Investments in education, healthcare, and infrastructure contribute to improved human well-being and social equality. Technological innovation plays a crucial role in SSP1-2.6, with widespread adoption of clean and renewable energy sources, energy-efficient technologies, and sustainable agricultural practices. Carbon capture and storage (CCS) technologies are deployed to reduce emissions from industries and power generation.

Stringent environmental regulations are implemented globally to limit greenhouse gas emissions and protect natural ecosystems. International cooperation is strong, with countries collaborating on climate mitigation efforts through mechanisms such as carbon pricing and technology transfer. As a result of these efforts, greenhouse gas emissions are significantly reduced, leading to a trajectory consistent with limiting global warming to 2.6°C or lower by the end of the century.

SSP5-8.5 (Fossil-Fueled Development Pathway):

SSP5-8.5 represents a future where socioeconomic development is characterized by high population growth, rapid urbanization, and reliance on fossil fuels. In this scenario, there is limited international cooperation, and efforts to address climate change are insufficient to curb greenhouse gas emissions effectively. The SSP5-8.5 Scenario features uneven economic growth, with disparities in wealth and access to resources. Urbanization is rapid, leading to increased energy demand and environmental degradation in some regions. Technological progress in SSP5-8.5 is driven by market forces and economic considerations rather than sustainability goals. There is continued reliance on fossil fuels for energy production, transportation, and industrial processes, leading to high greenhouse gas emissions. Environmental regulations in SSP5-8.5 are relatively weak, and there is limited international cooperation on climate mitigation efforts. Policies prioritize economic growth and energy security over environmental protection. Greenhouse gas emissions continue to rise unchecked in SSP5-8.5, leading to significant global warming and associated climate impacts such as sea-level rise, extreme weather events, and ecosystem disruption. The trajectory of warming under this scenario exceeds 8.5°C above pre-industrial levels by the end of the century.

These scenarios represent two contrasting futures based on different socioeconomic pathways and climate policies, highlighting the importance of global action to address climate change and transition towards sustainable development. Future projections of precipitation and mean temperature changes for each scenario are given for Antalya province in the figures below.



Source: World Bank, Climate Change Portal, 2024 (https://climateknowledgeportal.worldbank.org/country/turkiye/trends-variability-projections).

Figure X.64 Projected Precipitation Change Distributions of Antalya according to SSP1-2.6 and SSP5-8.5

The summary of the evaluations of the given images above are comprised below:

- According to the SSP1-2.6 scenario, the average air temperature in Antalya is expected to increase by approximately 1.5 degrees by 2039, approximately 2 degrees by 2059, approximately 2.1 degrees by 2079, and approximately 2 degrees by 2099.
- According to the SSP1-2.6 scenario, the average precipitation in Antalya is expected to decrease by approximately 49.8 mm to 862.5 mm by 2039, by approximately 51.9 mm to 860.4 mm by 2059, by approximately 46.5 mm to 865.8 mm by 2079, and by approximately 50.3 mm to 861.9 mm by 2099.
- According to the SSP5-8.5 scenario, the average air temperature in Antalya is expected to increase by approximately 1.7 degrees by 2039, approximately 2.8 degrees by 2059, approximately 4.1 degrees by 2079, and approximately 5.6 degrees by 2099.
- According to the SSP5-8.5 scenario, the average precipitation in Antalya is expected to decrease by approximately 50.6 mm to 861.7 mm by 2039, by approximately 92.6 mm to 819.7 mm by 2059, by approximately 154.32 mm to 757.9 mm by 2079, and by approximately 232 mm to 680.2 mm by 2099.

The projections for the SSP1-2.6 and the SSP5-8.5 scenario regarding average air temperature and average precipitation in Antalya are provided in the Table X.64 and Table X.65.

Table X.64 Changes in Average Precipitation in Antalya According to SSP1-2.6 and SSP5-8.5 Scenarios

Scenario	Historical Ref Period 1995-2014	2020-2039	2040-2059	2060-2079	2080-2099
SSP1-2.6 (mm)	912.3	862.5	860.4	865.8	861.9
SSP5-8.5 (mm)	912.3	861.7	819.7	757.9	680.2

Table X.65 Changes in Average Air Temperature in Antalya According to SSP1-2.6 and SSP5-8.5 Scenarios

Scenario	Historical Ref Period 1995-2014	2020-2039	2040-2059	2060-2079	2080-2099
SSP1-2.6 (^{O}C)	13.8	15.3	15.8	15.9	15.8
SSP5-8.5 (^{O}C)	13.8	15.5	16.6	17.9	19.5

The meteorological conditions of the Project area are evaluated in terms of meteorological and climatic characteristics according to the observations of Manavgat Meteorological Stations. According to Manavgat Meteorology Station records, the number of annual average snowy days is 0.1 and annual average number of days with snow covered is 0.02. The average annual total number of stormy days is 2.49 with the highest average in September (see Table X.45). According to these data;

In the SSP1-2.6 scenario, characterized by low carbon emissions and sustainable development policies, a reduction in the number of snowy days and snow-covered days can be expected due to an overall warmer climate. The total frosty days might not show a significant change as frost events are primarily related to cold weather conditions, which may not change noticeably in this scenario. The total stormy days are not expected to change significantly in the SSP1-2.6 scenario due to the relatively lower impact of climate change.

In contrast, the SSP5-8.5 scenario, characterized by high carbon emissions and low environmental policies, might lead to either a decrease or increase in snowy days and days covered with snow, but generally, a decrease is expected in a warmer climate. The total frosty days would likely decrease in the SSP5-8.5 scenario due to overall warmer temperatures and reduced frost occurrences. There might be an increase in total stormy days in the SSP5-8.5 scenario due to higher temperatures and more pronounced climate change effects.

Meteorological and Climate Characteristics, as seen in Table X.40, the highest temperatures of the year (above 40 degrees Celsius) were recorded in May, June, July, August and September. The lowest temperature was observed in February with an average temperature of -2.8 degrees. According to these data;

In the SSP1-2.6 scenario, there might be an increase in the highest temperatures recorded during the seasonal months, but this increase is not likely to be significant. Given that the lowest temperature is recorded at -2.8 degrees Celsius in January, no significant change in average lowest temperatures is expected under the SSP1 scenario.

In the SSP5-8.5 scenario, there could be an increase in the highest temperatures recorded during the seasonal months. Higher carbon emissions and increased greenhouse gases could elevate temperatures. Under the SSP5-SSP8.5 scenario, with the lowest temperature recorded at -2.8 degrees Celsius in January, there might be an increase in average lowest temperatures.

Assessment of Possible Exposures Caused by Climate Change

As can be seen from the results of the scenario used to determine the impacts that may occur due to climate change, it has been revealed that extreme temperature changes and decrease precipitation may occur. The Project infrastructure is likely to be affected by these extreme weather conditions. Potential impacts and adaptation measures to be taken are summarized in this section.

Water Drainage Infrastructures: It may cause deformations, cracking and corrosion in the materials and structure of water discharge substructures. Especially concrete structures can be sensitive to extreme temperatures and cold temperatures. While cracking may occur in materials that expand under extreme heat, brittleness and cracking of materials may occur under extreme cold.

As a result of changes in the amount, intensity and distribution of precipitation, water drainage infrastructures will be under more stress during excessive precipitation and the risk of floods may increase. In addition, impacts such as sea level rise may affect the design and resilience of drainage infrastructure. Extreme weather events can make it difficult to access infrastructure. Especially during heavy rainfall, problems such as clogging and cleaning of drainage systems may occur.

Working Days: Working in extreme heat can lead to heat-related health problems/illnesses such as heat exhaustion, heatstroke, and dehydration, impacting workers' health and productivity. High temperatures can decrease employees' concentration, physical endurance, and overall performance, leading to lower productivity levels. Extreme heat can create hazardous working conditions, increasing the risk of accidents and injuries among workers. High temperatures can also affect the functioning of machinery, electronics, and other equipment, causing delays and disruptions in work processes.

Working in extreme cold can result in health issues like frostbite, hypothermia, and respiratory problems, compromising workers' well-being and ability to work effectively. Cold temperatures can cause equipment malfunctions, frozen pipes, frost on the motorway, and other technical issues, impacting productivity and workflow.

Precipitation can lead to road closures, traffic congestion, and public transportation delays, affecting employees' ability to reach the workplace. Flooding and severe storms can damage buildings, roads, and utilities, causing disruptions in business operations and potentially leading to temporary closures.

In summary, extreme high and low temperatures, as well as extreme precipitation, can pose health risks, reduce efficiency, create safety hazards, disrupt transportation, and damage infrastructure, all of which can impact working days and business continuity.

Machinery and Equipment: Extreme hot weather conditions can adversely affect the performance of some machinery equipment. Electronic equipment can overheat and lose functionality when exposed to high temperatures. This is particularly crucial for computers, traffic control systems, and other sensitive electronic devices. Additionally, effects such as expansion of metal parts and changes in the viscosity of oils can also impact the mechanical components of machinery equipment.

Extreme cold weather conditions can also have adverse effects on machinery equipment. Materials such as lubrication systems, hydraulic systems, and plastic components may be less effective in extreme cold. Issues like freezing and becoming brittle can occur with metal parts. Additionally, extreme cold weather conditions can negatively impact the performance of chemical components such as batteries and accumulators.

Slope and Stability: Slope and pile stability depends on the type of soil, capillary structures, water permeability and water holding capacity. Water-absorbent soils such as clay may be more affected by precipitation, while sandy soils may allow water to pass through faster. The slope and height of the pile have a significant influence on stability. Steep slopes or high piles can be more susceptible to the impact of precipitation and therefore cause greater changes in stability. Both heavy precipitation and continuous moderate Precipitation can increase the saturation of the ground and the risk of erosion. Especially severe and prolonged precipitation can lead to soil erosion and the risk of landslides.

Landslides: Landslides are the downslope movement of soil, rock, or debris under the influence of gravity, often triggered by factors such as heavy precipitation, seismic activity, or human-induced changes to the landscape. The occurrence and severity of landslides depend on soil composition, slope angle, and moisture content. Saturated soils, particularly those with high clay content, are more prone to sliding due to reduced shear strength, while rocky or sandy terrains may resist movement unless destabilized by external forces. Steep slopes or areas with significant elevation changes are especially vulnerable, as they amplify gravitational pull. Prolonged or intense precipitation can exacerbate landslide risk by increasing pore water pressure and eroding stabilizing soil structures, leading to rapid and destructive mass wasting events.

Wildfires: The risk and spread of wildfires depend on vegetation type, moisture levels, weather conditions, and topography. Dry and resin-rich vegetation, such as coniferous forests or shrubs, can ignite more easily and burn rapidly. Low humidity, high temperatures, and strong winds significantly increase fire risk and intensity. The slope of the terrain also plays a crucial role; fires move more quickly uphill due to preheating of vegetation. Prolonged droughts or consecutive hot days can dry out fuel sources, creating highly flammable conditions. Wildfires can be sparked by sudden ignition sources such as lightning strikes or human actions, but they are also greatly fueled by ongoing dry conditions. And in areas where forest maintenance is lacking or where dead plant material has accumulated, fires can escalate rapidly and spread without control, endangering both natural environments and nearby communities.

Snowfall:

Snowfall impacts terrain stability, infrastructure, and safety, depending on snow volume, temperature, slope angle, and soil properties. Heavy snow accumulation adds weight to slopes, increasing the risk of avalanches, especially on steep terrains or areas with loose snow. Rapid snowmelt, triggered by warm temperatures or rain, can oversaturate soils, reducing cohesion and promoting landslides, particularly in fine-grained or clay-heavy soils. Prolonged snowfall or intense snowstorms can increase the risk of slope failure by overloading the terrain. Freeze-thaw cycles weaken the soil structure and further destabilize the slopes.

Adaptation Measures for Climate Change Impacts

Water Drainage Infrastructures:

- General hydrological considerations/design of the Project will be in accordance with KGM design standards and AASHTO Highway Drainage Principles. In this regard, generally, 100-year flood flow will be taken into account on stream passage designs (Ref. State Highways Technical Requirements, Item 9.3). Minimum dimensions of all culverts will be 2m x 2m except discharge culverts.
- Culverts will be designed with one outlet whenever possible. In order to minimize changes in the hydrology and flow of water courses, design of structures will be done accordingly. The design will also ensure an appropriate capacity for culverts through embankments when flood plains are cut off.
- The design will be done in a way to minimize the risks of flooding. During the operation phase, reviewed Emergency Preparedness and Response Plan will be used to mitigate flood events.
- Storm water management practices that slow peak runoff flow, reduce sediment load, and increase infiltration, including vegetated swales (planted with salt-resistant vegetation), filter strips, terracing, detention ponds or basins, and infiltration trenches, will be planned.

Working Days:

- Adjustments will be made to working hours based on weather forecasts to avoid working during periods of extreme heat, heavy rainfall or high winds.
- Predicted changes in weather conditions will be monitored using meteorological stations and work schedule will be planned according to this information.
- Shaded rest areas will be provided for workers during hot weather periods, adequate water supply will be ensured and heat-related illnesses and injuries will be prevented by taking frequent breaks.
- During periods of cold weather, workers will be provided with appropriate protective equipment such as insulated clothing, gloves and shoes.
- Storm preparedness plans will be developed for workers that include procedures for evacuating work areas during storms or lightning storms.
- Workers will be trained on emergency response procedures specific to climate-related events.

Machinery and Equipment:

- Materials resistant to climate change will be selected. Regular maintenance/repair and monitoring of machinery equipment will be provided.
- Protection of machinery and equipment will be ensured through appropriate drainage system designs.
- Energy efficient machinery and equipment will be preferred to minimize the contribution to climate change.
- Emergency response plans will be developed for climate-related events that may have an impact on machinery and equipment. This will include equipment shutdown protocols, evacuation procedures, and emergency plans for rapid repairs and recovery.

Slope and Stability:

- Retaining walls will be constructed in certain sections to ensure ground and slope stability.
- Areas prone to slope instability resulting from climate change factors, such as increased precipitation, soil erosion or temperature fluctuations, will be identified and these areas will be constantly monitored.
- Water will be removed from the slopes using structures such as waterways, culverts and erosion control structures.
- Vegetation management measures will be implemented to stabilize slopes and reduce soil erosion.
- Comprehensive risk assessments will be conducted to identify potential hazards associated with slope instability in changing climate conditions.
- Provide training to employees on slope stability principles, climate change impacts and adaptation strategies.

Landslides:

- Early warning systems will detect landslide triggers like heavy rain or ground shifts in high-risk areas.
- Zones prone to landslides due to increased precipitation or soil saturation will be mapped and monitored.
- Drainage systems, such as channels and barriers, will divert water to reduce slope saturation.
- Vegetation and bioengineering will stabilize slopes and curb erosion via root systems.
- Geotechnical assessments will evaluate landslide risks under changing climate conditions.
- Staff training will cover landslide prevention and climate impact response strategies.

Wildfires:

- Firebreaks and buffer zones will be established in strategic areas to slow the spread of potential wildfires.
- Regions with high wildfire risk due to climate change factors—such as prolonged drought, rising temperatures, and reduced humidity—will be identified and regularly monitored.

- Dry vegetation, dead wood, and other combustible materials will be removed through regular clearing and controlled burns to reduce available fuel.
- Native, fire-resistant plant species will be used in vegetation management to help limit the spread and intensity of fires.
- Detailed wildfire risk assessments will be conducted, taking into account climate projections, local vegetation, and topography to guide mitigation strategies.
- Employees will receive training on wildfire prevention, emergency response procedures, and the effects of climate change on fire behavior.

Snowfall:

- Early warning systems will use meteorological data to detect heavy snowfall or blizzard conditions.
- Areas prone to heavy snowfall due to climate-driven changes will be mapped and monitored.
- Cold-resistant vegetation and slope stabilization measures will be applied to reduce snow-induced erosion.
- Geotechnical and environmental assessments will evaluate snowfall-related risks along the motorway.
  Employee training will cover snow hazard awareness, safe removal practices, and climate adaptation strategies.

Physical Climate Impacts of Hazards

The physical risk impacts will have a negative effect on both phases of the project, as they are likely to cause delays in the overall timeline. These disruptions can hinder progress during the starting stages and continue to affect subsequent phases, ultimately compromising the efficiency and timely completion of the project.

The project route traverses multiple high-risk areas that are susceptible to a range of different types of hazards. These include environmental, geotechnical, and climate-related risks such as wildfire-prone zones, areas vulnerable to flooding and landslides, regions with unstable soil conditions, and locations exposed to extreme temperatures and weather events

The hazard levels were calculated using data from the Antalya Metropolitan Municipality's SECAP (Sustainable Energy and Climate Action Plan) document by analyzing the likelihood and possible impact of each climate-related hazard. The hazard level for each hazard was determined using the standard formula: Hazard Level = Likelihood × Impact. The Table X.66 summarizes the assessment results and provides explanations based on local climatic conditions and their potential effects on construction activities in the region.

Table X.66 Physical Climate Risk Hazard Level Matrix

Hazard	Likelihood	Possible Impact	Hazard Level	Explanation
Wildfires	High	High	**High**	Antalya's hot, dry summers spark wildfires, threatening construction sites, equipment, and closing operational motorways.
Extreme Rainfall, Floods	High	High	**High**	Extreme rainfall events erode construction sites, damage road surfaces, and disrupt traffic flow..
Water Scarcity and Drought	High	High	**High**	Droughts limit water for construction (e.g., concrete mixing) and road maintenance (e.g., cleaning).
Heatwaves	High	High	**High**	Heatwaves risk worker health during construction, degrade asphalt, and affect driver safety in operation
Storms, Strong Winds, and Tornados	High	High	**High**	Storms damage temporary construction structures and disrupt operations with debris and signage damage.
Cold Waves	Medium	Medium	**Medium**	Rare cold waves delay construction, affect material curing, and create icy patches during operation.
Snowfall	Low	Medium	**Medium**	Rare snowfall halts construction and requires snow removal to maintain operational motorway safety.

The risk levels were calculated using data from the Antalya Metropolitan Municipality's SECAP (Sustainable Energy and Climate Action Plan) document by analyzing the likelihood and possible impact of each climate-related hazard. The updated risk analysis incorporates a more detailed approach by evaluating the hazard level, the exposure, sensibility/vulnerability, and overall risk level for each hazard for the project cycle based on the construction schedule, material integrity, worker safety, and operational efficiency. The table below (Table X.72) categorizes the identified risks according to these factors.

Table X.67 Physical Climate Risk Analysis Matrix

Hazard	Hazard Level	Exposure	Sensibility/ Vulnerability	Risk Level
Wildfires	High	High	High	**High**
Extreme Rainfall, Floods	High	High	High	**High**
Water Scarcity and Drought	High	High	Medium	**High**
Heatwaves	High	High	High	**High**
Storms, Strong Winds, and Tornados	High	High	Medium	**High**
Cold Waves	Medium	Medium	Medium	**Medium**
Snowfall	Medium	Medium	Low	**Medium**

Table X.68 presents the physical climate risks identified for the project, their possible impacts, corresponding risk levels, and recommended risk management and mitigation measures. And also, outlines each risk, its potential impact on the project, and the associated risk level, along with suggested strategies to mitigate or manage these risks.

Table X.68 Possible Impacts of Physical Risks

Physical Climate Risks	Possible Impacts on the Project	Risks Levels	Risk Management and Mitigation Ideas
Wildfires	• Traffic disruptions: Road closures or detours due to nearby fires or poor visibility from smoke. • Infrastructure damage: Melting of signs, lighting systems, and deformation of asphalt surfaces. • Safety hazards: Increased accident risk from reduced visibility and sudden evacuations. • Maintenance interruptions: Delays or hazards in routine road operations and repairs. • Post-fire hazards: Soil instability, erosion, and potential landslides affecting road safety and function.	High	• Heat-resistant concrete additives and asphalt binders designed for high temperatures to ensure proper curing and durability. • Detection systems and visibility sensors along roads to provide early warnings. • Maintenance during low-fire-risk seasons. • Slope stabilization techniques for post fire to prevent landslides.
Extreme Rainfall, Overflow and Floods	• Climate-induced disruptions such as floods, flooding in transportation networks can delay the delivery of critical materials, impacting project schedules and budgets. • Climate-induced disruptions such as droughts, heavy rainfall, or flooding can cause variability in soil moisture that undermines ground stability, requiring additional site service before construction can proceed.	High	• Weather forecasting tools to anticipate delays and adjust schedules. • Implement drainage systems.
Water Scarcity and Drought	• Disruptions as water becomes scarce and the availability of water for construction activities such as dust suppression or concrete mixing becomes low. • Delayed maintenance due to water restrictions. • Degradation of roadside ecosystems • Potential conflict with local communities over shared water resources.	High	• Adopt water-efficient technologies If possible, on-site water should be recycled. • Use of drought-resistant vegetation alongside of the motorway. • Engagement with local communities to agree on shared water resource plans.
Heatwaves	• High temperatures and humidity can adversely affect the curing of concrete and laying of asphalt, potentially compromising material quality and construction timelines. • Exposure to extreme heat or severe weather conditions increases health risks for construction workers, often necessitating reduced work hours or changing safety protocols.	High	• Heat-resistant concrete additives and asphalt binders designed for high temperatures to ensure proper curing and durability. • Asphalt laying and concrete pouring during cooler parts of the day • Heat stress management plans, including mandatory breaks in shaded or cooled areas, hydration stations. • Flexible scheduling to account for reduced work hours during extreme heat. • Real-time heat index monitoring to adjust work.
Storms, Strong Winds and Tornados	• Disruption of motorway infrastructure due to damage to signage, lighting, and barriers. • Disruption of traffic flow from fallen debris and road closures. • Disruption of vehicle safety from strong crosswinds. • Disruption of operations from construction delays and power outages.	High	• Wind-resistant signage, lighting, and barriers • High-strength steel or composites to withstand storm • Real-time debris detection systems • Response teams to manage road closures and rerouting during storm events • Wind speed sensors along the motorway to warn drivers with electronic message signs
Cold Waves and Snowfall	• Delays in construction activities due to frozen ground, limited visibility, and reduced worker efficiency in cold conditions. • Increased risk of accidents on-site and on access roads due to icy or snow-covered surfaces. • Damage to materials and machinery not suited for low temperatures or inadequate winter storage. • Disruption of transportation and logistics, including delayed deliveries and restricted access to the project site. • Additional maintenance burdens from snow removal, de-icing, and ensuring operational safety during prolonged cold events.	Medium	• Provide insulated storage or heated shelters for temperature-sensitive materials and equipment. • Implement de-icing and snow removal protocols for construction and operation areas and the Project roads. • In winter, equip the motorway with snowplows and salt spreaders to maintain accessibility and safety. • Monitoring of snowfall and temperature conditions to trigger response measures.

X.2.4. Mitigation Measures

The following subsection describes the actions and strategies designed to avoid, minimize or offset the potential adverse impacts of the Project on climate change, or to enhance potential Project benefits.

X.2.4.1. Land Preparation and Construction Phase

Türkiye's NDC commits to a 41% reduction in GHG emissions by 2030 relative to the Business-As-Usual (BAU) scenario, with a peak in emissions by 2038. GHG emissions generated during land preparation and construction phase of the Project can be considered as relatively short term emissions when compared to the emissions of operation of the Motorway. The Project adopts several mitigation measures to minimize its carbon footprint and support the country's climate commitments under both the NDC and National Climate Change Strategy (NCC).

Construction activities will be carried out in accordance with good industrial practices, with a focus on energy efficiency and emission reduction:

- High-efficiency and low-emission construction machinery will be prioritized at construction sites to minimize fuel consumption.
- Regular maintenance of equipment will be conducted to improve engine efficiency and reduce the idling time of stop-and-go heavy vehicles.
- Electricity demand during construction activities will be met as much as possible through renewable energy sources.
- The use of recycled and locally sourced materials will be encouraged to reduce indirect emissions from material transportation.
- An effective waste management plan will be implemented to control organic waste that may cause methane emissions
- These measures aim to reduce the carbon footprint during the construction phase and enhance environmental sustainability.

Through these measures, the Project contributes to national climate targets by reducing GHG emissions during the construction phase and promoting long-term environmental sustainability.

X.2.4.2. Operation Phase

Various strategies have been adopted to reduce greenhouse gas emissions during the operation phase of the motorway. The new motorway route aims to reduce fuel consumption of vehicles by improving traffic flow and minimizing stop-and-go traffic on the existing road network. And ensuring that the motorway access connects to low-carbon public transports, such as buses, or other public transport, this will result in shorter travel times and a reduction in direct CO_2 emissions from vehicles. In addition, charging stations are planned to be installed in each of the four service areas planned along the route to encourage the use of electric vehicles (EVs), in alignment with Türkiye's Nationally Determined Contributions (NDC) transport decarbonization goals.

Energy-efficient LED technologies will be used in tunnels, intersections, and lighting systems, and there will be a shift towards low-carbon energy sources for electricity consumption. Environmentally friendly materials and practices will be preferred in road maintenance and operation activities to reduce indirect emissions. And in the future, the project envisages using electric or hybrid vehicles for maintenance and renewable energy for operations to contribute to the net-zero goals by 2053, as outlined in the National Climate Change Strategy (NCC) and NDC.

To compensate for the environmental impact caused by tree cutting, five times the number of trees to be cut will be planted. The Project also plans to protect remaining vegetation, stabilize soil through erosion control, establish green buffer zones along the motorway, regularly monitor forest recovery and carbon storage, and engage local communities in sustainable forest management.

All these measures demonstrate the Project's alignment with Türkiye's climate commitments under the NDC and NCC and will be monitored and reported to align with the 41% reduction target in 2030 ensure that the Antalya–Alanya Motorway serves as a low-carbon transport infrastructure in the long term from existing road network.

X.2.5. Summary of Assessment and Residual Impact

This section provides a summary of the various calculations in the above subsections. The results for annual Scope 1 and Scope 2 are presented bellow in Table X.69.

Table X.69 Summary of Annual Emissions for Scope 1 and Scope 2

Construction Phase	**Emissions per year ($t CO_2 e$)**
Scope 1	85,232.91
Scope 2	12,380.44
Total	**97,613.35**
Operation Phase	**Emissions per year ($t CO_2 e$)**
Scope 1	1,192.84
Scope 2	9,315.35
Total (Scope 1 and Scope 2)	**10,508.19**

During the construction and operation phases of the Antalya-Alanya Motorway Project, the total annual Scope 1 and Scope 2 greenhouse gas emissions resulting from diesel, LNG, and electricity consumption were estimated at approximately 97,613.35 tons and 10,508.19 tons of CO_2 equivalent, respectively, both remaining below the limits set by the Equator Principles. Additionally, due to tree clearing in forested areas throughout the project duration, a 0.62% reduction in regional carbon sequestration and oxygen production capacity is expected, reflecting the impact on the forest resources within the project area. The Project has demonstrated compliance with national and international standards for greenhouse gas management.

The summary of the assessment made in the general framework is provided in Table X.70. Assessment based on sensitive locations/receptors, project stages, air quality measurement results and air quality modeling studies were made in this ESIA Report.

Table X.70 Summary of Air Quality and GHG Assessments

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Land Preparation and Construction Phase												
Increase in PM_{10}, $PM_{2.5}$ concentrations, Settled Dust	Local Communities: Akdam, Avsallar, Bademliyar, Bucakşeyhler, Çakallar, Deniz Tepesi, Emişbeleni, Hacıali, Hacıobası, Kalemler, Karakaya, Konaklı, Köprüçay, Sağırin, Sarılar, Sarıabalı, Serik, Sülek, Taşağıl, Ulukapı, Uzunlar	Adverse	Local	Medium	Low (0-25 % exceedance of air quality standard)	Short term reversible	Intermittent	Medium (B)	Moderate (2)	Medium (B2)	• Dust should be minimized from material handling sources, such as conveyors and bins, by using covers and/or control equipment (water suppression, bag house filters or cyclones). • Dust should be minimized from open area sources, including storage piles, by using control measures such as installing enclosures and covers, and increasing the moisture content. • Speed limitations will be defined and obeyed for construction vehicles. • Well and adequate maintained vehicles shall be used. Regular maintenance of machinery and equipment will be ensured. • The drop height of potentially dust generating materials will be kept as low as possible. • Construction vehicles will not be permitted to keep engines running while waiting to enter the site or waiting on-site. • Dust suppression methods (i.e. watering with water trucks, applying non-toxic chemicals, speed limits for mobile vehicles, use of well-maintained vehicles/machinery) will be applied at road construction sites, service roads and quarry/material borrow/storage sites to mitigate Project-related dust emissions. Watering will be applied at any time necessary including night time, weekends or off-days by using pressurized distribution or spraying systems that would ensure even distribution of water. • If there is traffic flow on the existing roads near the work sites, dust suppression measures will be continuously applied to ensure traffic safety. If there is no traffic existing in the local roads, dust suppression measures will be applied only at local residential and business areas. • All the dust-emitting components of the crushing-screening plants will be put in closed spaces and equipped with dust suppression systems. • Loading and unloading operations will be performed without throwing/scattering. • During the transportation of the excavated materials outside the construction site, the material will be covered with nylon tarpualin. • In the supply of construction materials, local licensed quarries (existing or new) will be preferred to reduce transportation distance to minimize associated impacts and costs. • Wind shields/barriers will be placed at work sites such as material storage areas to prevent dust dispersion where necessary. • Relevant provisions of the Regulation on Air Pollution Control Sourced from Industry and Regulation on the Assessment and Management of Air Quality will be complied with to minimize air emissions sourced from construction machinery and trucks. • Blasting operations will be conducted in line with the legislation in force and good industry practices/modern techniques. • Roads to be used for access to quarry sites will be upgraded by the Project Sponsor to minimize dust emissions during transport. These roads will have sufficient width. • Exhaust emission measurements of the vehicles will be conducted periodically every three months. • Driving through settlements will be avoided wherever alternative roads are present. • Any damage caused by insufficient or lack of dust suppression measures will be compensated. • High-dust construction activities near Hacıali neighborhood shall be avoided during stagnant meteorological conditions or temperature inversion events. • To control fugitive dust emissions in the vicinity of Hacıali neighborhood, water spraying, application of soil stabilizers, and road paving will be implemented. • All material-transporting trucks operating along routes near Hacıali neighborhood	Low
	Ecologically Sensitive Areas Taşağıl, Sarıabalı	Adverse	Local	Medium	Low (0-25 % exceedance of air quality standard)	Short term reversible	Intermittent	Medium (B)	Moderate (2)	Medium (B2)		Low

											shall be covered as part of dust control measures. • Wind fences or vegetative barriers will be installed between emission sources and the Hacıali neighborhood. Additionally, air quality monitoring stations will be established at appropriate location around these neighborhood, and regular measurements will be conducted.	
GHG (Greenhouse Gas)	Settlement areas along the Project route	Adverse	Wide	Medium	Medium (25,000-100,000 t CO_2 e)	Short term reversible	Intermittent	Wide (A)	Moderate (2)	High (A2)	• High-efficiency and low-emission construction machinery will be prioritized at construction sites to minimize fuel consumption. • Regular maintenance of equipment will be conducted to improve engine efficiency and reduce the idling time of stop-and-go heavy vehicles. • Electricity demand during construction activities will be met as much as possible through renewable energy sources. • The use of recycled and locally sourced materials will be encouraged to reduce indirect emissions from material transportation. • An effective waste management plan will be implemented to control organic waste that may cause methane emissions. • These measures aim to reduce the carbon footprint during the construction phase and enhance environmental sustainability. • To compensate for the environmental impact caused by tree cutting, five times the number of trees to be cut will be planted.Preserving existing trees and plants to prevent further loss. • Creating vegetated areas along the motorway to reduce the impacts. • Involving locals in sustainable forest management and restoration.	Medium
Operation Phase												
Increase in concentrations of gasous pollutants	Local Communities Akdam, Avsallar, Bademliyar, Bucakşeyhler, Çakallar, Deniz Tepesi, Emişbeleni, Hacıali, Hacıobası, Kalemler, Karakaya, Konaklı, Köprüçay, Sağırin, Sarılar, Sarıabalı, Serik, Sülek, Taşağıl, Ulukapı, Uzunlar	Adverse	Local	Long	Low (0-25 % exceedance of air quality standard)	Irreversible	Continuous	Wide (A)	Low (1)	Low (A1)	• At the service areas, a green buffer strip will be formed between the outer lane of the Motorway and the facilities. This strip will be properly planted (e.g. with shrubs that start growing from the base and are resistant to dust and gaseous emissions) to form a barrier against dust to be sourced from the Motorway's vehicle traffic. • The application of automatic toll systems along the Motorway will contribute to an optimization of traffic flows and thus lower emissions.	Low
	Ecologically Sensitive Areas Taşağıl, Sarıabalı	Adverse	Local	Long	Low (0-25 % exceedance of air quality standard)	Irreversible	Continuous	Medium (B)	Moderate (2)	Medium (B2)		Low
GHG (Greenhouse Gas)	Settlement areas along the Project route	Adverse	Wide	Long	Medium (25,000-100,000 t CO_2 e)	Irreversible	Continuous	Wide (A)	Moderate (2)	High (A2)	• Various strategies have been adopted to reduce greenhouse gas emissions during the operation phase of the motorway. • The new motorway route is designed to improve traffic flow and reduce stop-and-go traffic, thereby lowering fuel consumption. • These improvements will result in shorter travel times and reduced direct CO_2 emissions from vehicles. • To encourage the use of electric vehicles (EVs), charging stations will be installed in each of the 4 service areas planned along the route. Energy-efficient LED technologies will be used in tunnels, intersections and lighting systems.	Medium

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
											• There will be a shift toward low-carbon energy sources for electricity consumption. • Environmentally friendly materials and practices will be preferred in road maintenance and operation activities to reduce indirect emissions. • Collectively, these measures will ensure that the Antalya–Alanya Motorway serves as a low-carbon transport infrastructure in the long term.	
Pysical Risks	Infrastructure and Natural Enviornement	Adverse	Wide	Short	Major	Reversible	Recurrent	Wide (A)	High (3)	High (A3)	• Heat-resistant concrete additives and asphalt binders designed for high temperatures to ensure proper curing and durability. • Detection systems and visibility sensors along roads to provide early warnings. • Maintenance during low-fire-risk seasons. • Slope stabilization techniques for post fire to prevent landslides. • Weather forecasting tools to anticipate delays and adjust schedules. • Implement drainage systems. • Adopt water-efficient technologies • If possible, on-site water should be recycled. • Use of drought-resistant vegetation alongside of the motorway. • Engagement with local communities to agree on shared water resource plans. • Heat-resistant concrete additives and asphalt binders designed for high temperatures to ensure proper curing and durability. • Asphalt laying and concrete pouring during cooler parts of the day • Heat stress management plans, including mandatory breaks in shaded or cooled areas, hydration stations. • Flexible scheduling to account for reduced work hours during extreme heat. • Real-time heat index monitoring to adjust work. • Wind-resistant signage, lighting, and barriers • High-strength steel or composites to withstand storm • Real-time debris detection systems • Response teams to manage road closures and rerouting during storm events Wind speed sensors along the motorway to warn drivers with electronic message signs	Medium
		Adverse	Wide	Short	Medium	Reversible	Recurrent	Medium (B)	Moderate (2)	Medium (B2)	• Provide insulated storage or heated shelters for temperature-sensitive materials and equipment. • Implement de-icing and snow removal protocols for construction and operation areas and the Project roads. • In winter, equip the motorway with snowplows and salt spreaders to maintain accessibility and safety. • Monitoring of snowfall and temperature conditions to trigger response measures.	Low

* *The impacts mentioned above have been assessed based on the worst-case scenario, and it is expected that the actual impacts will occur at lower levels with the implementation of the proposed air quality and climate change mitigation measures.*

XI. NOISE AND VIBRATION

This chapter assesses the anticipated noise and vibration impacts of the Project. In this context, the land preparation and construction, and operation phases of the Project are considered, and the associated impacts are evaluated accordingly. In the final ESIA, this chapter will cover the following aspects:

- Legislative framework for environmental noise, and vibration assessment,
- Baseline environmental noise measurements,
- Assessment and quantification of potential Project emissions,
- Noise modeling with SoundPLAN V 9.1 software for land preparation and construction, and operation phases of the Project,
- Assessment of potential noise and vibration impacts,
- Mitigation measures regarding assessed impacts, and
- Residual impacts regarding noise impacts.

XI.1. Noise

Noise is defined as an undesired sound that is loud or unpleasant or that causes disturbance. Sound consists of vibrations transmitted to the ear as rapid variations in air pressure. In other words, sound is a disturbance propagated through the air as a pressure wave. The fluctuations in atmospheric pressure are sensed by the ear. Frequency is the number of pressure fluctuations per second and is expressed in Hertz (Hz). In other words, the frequency of sound is the rate at which a sound wave oscillates, measured in a number of cycles per second. The human ear is more sensitive to frequencies important for voice communication and hearing sensitivity decreases markedly at frequencies below about 250 Hz. The upper-frequency limit of audibility is around 20 kHz. The frequency of the pressure wave is converted to pitch and its amplitude is converted to loudness. The human ear can respond to a wide range of amplitudes and frequencies of sound.

The response of the hearing system to the amplitude of sound pressure is non-linear and can be characterized by a logarithmic relationship. The relationship is also frequency dependent and an adjustment or weighting is applied to the response of a microphone to different frequency components of a sound in order to produce a scale that better reflects the hearing system. In addition, in order to characterize sounds that fluctuate in intensity, it is necessary to derive a statistic that applies over a period of time.

Sound pressures are measured in units of Pascal (Pa). In order to cope with such a range of sound pressure values it is convenient to measure sound in terms of a logarithmic ratio of sound pressures. These values are expressed as sound pressure levels in decibels (dB).

Several different weightings have been proposed to convert measured sound pressure to a measure that correlates with perceived loudness in different circumstances. The ‘A’ weighting can be accepted as the most commonly used and correlates well with the perceived noisiness of road vehicles.

Traffic noise is a general term used to define the noise from traffic using the road network. A broad indication of typical traffic noise levels likely to be encountered at various distances from the road for two different traffic conditions is presented in Figure XI.1. The first is representative of a heavily trafficked road (about 150,000 vehicles per day) and the second is a lighter trafficked road (about 50,000 vehicles per day).

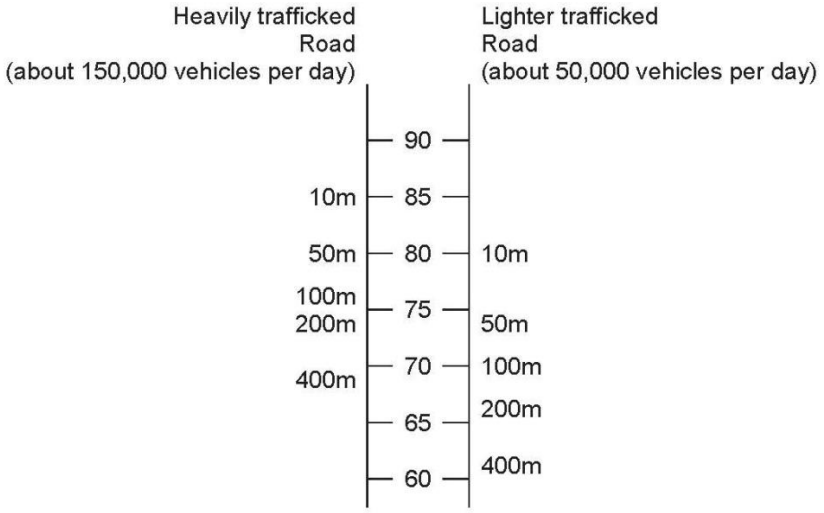

Figure XI.1 Example of Typical Traffic Noise Levels *(UK Highways Agency, 2011)*

XI.1.1. Assessment Methodology and Data Sources

XI.1.1.1. Legal Framework

Turkish Legal Requirements

Regulation on Environmental Noise Control (RENC)

Environmental noise in Türkiye is regulated by the Regulation on Environmental Noise Control (RENC) published on 30.11.2022 in Official Gazette No 32029. This regulation is intended to ensure that precautions are taken to prevent disturbance to peace and tranquility and to ensure the physical and mental health of persons potentially exposed to environmental noise. For this purpose, the regulation sets out requirements regarding noise mapping, acoustic reporting, environmental noise assessment to determine noise exposure levels, and preparation and application of action plans to prevent or mitigate the negative impacts of noise exposure on human beings and the environment.

According to the Regulation on Environmental Noise Control, noise limit values defined to prevent noise from road projects are defined in Annex II, Table 1. Environmental noise limits values defined in the RENC are presented in Table XI.1.

Table XI.1. Environmental Noise Limits Values

Noise Source	Measured Parameter	Environmental Noise Level		
		Day (07:00 – 19:00)	Evening (19:00 – 23:00)	Night (23:00 – 07:00)
Industrial plants, transportation resources	$LA_{eq,5min}$	65 dB(A)	60 dB(A)	55 dB(A)
Music broadcasting workplaces (1)	$LA_{eq\ 63\text{-}250\ Hz}$	60 dB(A)	55 dB(A)	50 dB(A)
Workplaces (2)	$LA_{eq,5min}$	Background + 5 dB(A)		Background +3 dB(A)
In case of multiple workplaces (3)	$LA_{eq,5min}$	Background + 7 dB(A)		Background +5 dB(A)
All resources	LC_{max}	100 dB(C)		

(1): These limit values are valid as of 31.12.2023. These limit values are provided in each 1/3 octave band of the specified frequency range. In the acoustic reports prepared until this date; environmental noise measurement results and measures determined as a result of the measurement results taken are included.
(2): Workplaces broadcasting music and sea vessels are included.
(3): Each workplace that contributes to the background noise level is equally responsible for ensuring this limit value. Each workplace takes the necessary measures according to their contribution to noise.

The Annex-2 Article 10 of RENC states that "The working hours of the construction activities of projects such as dams, bridges, tunnels, motorways, urban highways, mass housing which require public benefit and construction activities that will prevent daytime traffic in the city are determined by the decision of the Provincial Local Environmental Board." In this context, the permitted time zones for outdoor activities in residential areas that cause environmental noise are given in Table XI.2.

Table XI.2. Permitted Time Frame for Outdoor Activities in Residential Areas

Activity Name	Activity Time
Construction site activities	10.00-22.00
Outdoor activities that cause environmental noise	10.00-01.00
Use of fireworks	20.00-22.00
Blasting activities in mines, quarries, and other areas	10.00-20.00

As an exception to these time frames, according to Annex-2, Article 10 of the RENC, working hours for construction projects such as dams, bridges, tunnels, motorways, main urban roads, and mass housing developments that serve public interest and construction activities that are likely to disrupt daytime city traffic are set by the Provincial Local Environmental Board's decision.

International Finance Corporation (IFC) Standards

Noise limit levels are described under Environmental, Health and Safety (EHS) Guidelines, General EHS Guidelines: Environmental, Noise. The noise limit values are based on World Health Organization Guidelines for Community Noise. Noise levels defined by IFC are presented in Table XI.3.

Table XI.3. IFC Noise Limit Values

Receiving Environment	Hourly LAeq (dBA)	
	Day 07:00 - 22:00	Night 22:00 - 07:00
Residential, institutional and educational areas	55	45
Industrial, and commercial areas	70	70

IFC requires that noise impacts should not exceed the levels presented in Table XI.3. . If the background noise levels are above the standard levels, noise should not result in an increase in background noise levels more than 3 dB at the nearest receptor location off-site.

The IFC EHS Guideline also presents examples of noise reduction options that should be considered where noise levels exceed these guideline values, along with recommendations for noise monitoring to be carried out either to establish existing ambient noise levels or to verify operational noise levels.

In addition to the IFC General EHS Guidelines, the IFC EHS Guideline for Toll Roads offers guidance on noise management for road/motorway projects. While this guideline provides management practices to prevent, minimize, and control noise, it does not specify noise limit values. As a result, the guidance on noise management in this document is limited and was determined to have limited applicability to this Project.

When European Directives are reviewed, Directive 2002/49/EC namely, the Environmental Noise Directive states that “Member States shall designate at the appropriate levels the competent authorities and bodies responsible for implementing this directive: (a) making and, where relevant, approving noise maps and action plans for agglomerations, major roads, major railways and major airports; (b) collecting noise maps and action plans. Although the EU Environmental Noise Directive does not prescribe noise limits for new roads, such standards are expected to be established at the national level for member states. This directive requires that the member states apply the noise indicators L_{den} and L_{night} for noise assessment.

In summary, Turkish noise limits and IFC guidelines were utilized to assess the impacts of the Project on environmental noise levels.

Noise Assessment Criteria

Within the scope of the Project, noise assessments were carried out based on both the national regulation (RENC limit values) and the IFC limit values. Since IFC thresholds define more stringent criteria compared to RENC, the assessments were conducted in accordance with the stricter IFC standards.

Significance Criteria

The significance criteria for the impacts regarding noise will be determined, as high, medium or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter IV (“ESIA Methodology”) will be used for the determination of the magnitude of impacts, while sensitivity/value criteria to be used in the scope of impact assessment is summarized in Table XI.4.

Table XI.4. Criteria for Sensitivity/Value of Resource/Receptor

Receptor/Resource	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Human Receptors	Educational, cultural, health facilities, places densely populated with summer houses and camping areas and/or areas densely populated with residences	Areas with dense work places/ industrial areas and areas not densely populated with residences	Industrial / Rural areas

The magnitude of impacts was evaluated based on increase in baseline noise levels measured in settlements close to the Motorway route. The magnitude of impact is defined as low, medium and high when the result of modeling study increases baseline noise levels of a specified location 3-6 dBA, 6-9 dBA and more than 9 dBA, respectively (see Table XI.5). Furthermore, regardless of the increase in baseline noise level, the magnitude of impact is classified as high when results of noise modeling study indicate exceedance in noise limit values. Therefore, increases in noise levels up to 3 dB at a specified location are considered acceptable, with the impact magnitude defined as negligible.

Table XI.5. Impact Magnitude Criteria

Magnitude of Impact	Increase in Baseline Noise Level (L_{den} dBA)
Low	3-6 dBA
Medium	6-9 dBA
High	>9 dBA or noise modeling study indicates exceedance of noise limit values

XI.1.2. Baseline Conditions

As part of the ESIA studies, baseline noise measurements were conducted along and around the Antalya–Alanya Motorway route in September 2024 to determine the existing noise levels during both weekdays and weekends. Background noise measurements were conducted at 21 locations along and around the Antalya–Alanya Motorway route, with a focus on residential areas and sensitive receptors most likely to experience elevated noise levels. The selected measurement sites included locations near quarries, state highways, and other roads with heavy traffic to capture a representative range of existing noise conditions. These locations were chosen to ensure that the nearest sensitive receptors to the Project area were included in the baseline noise assessment. Therefore, background noise measurements were indeed conducted at the closest sensitive receptors to the Project area to accurately reflect existing noise levels.

Detailed information on the distances of residential buildings and sensitive receptors located near the Project alignment, as well as field conditions, is provided in Table XI.6. To visually support the noise monitoring campaign, representative weekday and weekend photographs were included from two selected locations: Emişbeleni Neighborhood, representing a rural residential setting, and Serik District, representing an urban environment. These photos were selected to illustrate the environmental context of the noise measurement points. Field photographs are provided in Figure XI.2 and Figure XI.3.

As shown in Figure XI.4, 24-hour continuous noise measurements were conducted at the 21 selected locations along the motorway alignment. The noise measurements were commissioned by ENCON Laboratuvarı A.Ş. and carried out in accordance with TS ISO 1996–2 standards by ANKALAB Çevre Analiz Laboratuvarı SAN. TİC. LTD. ŞTİ., an accredited laboratory authorized by the Ministry of Environment, Urbanization and Climate Change. The brand and model information of the equipment used, along with calibration and accreditation certificates, are provided in Annex-2. A summary of the measurement results is presented in Table XI.6.

The conducted noise measurements were compared against the equivalent continuous sound level (Leq) values specified for industrial plants and transportation resources in Table XI.1 of the Regulation on Environmental Noise Control, as well as the limit values for residential, institutional, and educational areas outlined in Table XI.3 of the IFC EHS Guidelines. The assessment results indicate that Leq levels measured during daytime, evening, and nighttime frequently exceed these thresholds at multiple locations. Notably, in settlements such as Bucakşeyhler, Bademliyar, Taşağıl, Hacıali, Karakaya, and Sağırin, noise levels during both day and night were observed to be significantly above the IFC limits. This is primarily attributed to the presence of various noise sources and sensitive receptors in close proximity. Measurement points were carefully selected to accurately represent the existing acoustic environment within the project area, covering a mix of 21 major road and state roads, 20 residential areas, 15 agricultural enterprises, 3 tourism sites, 3 schools, 1 mosque, and 4 rivers. This combination ensures representation of diverse conditions found in rural, semi-urban, and more developed areas, thereby capturing typical noise levels in locations where people live, work, and gather.Conditions that may result in high noise levels for each measurement point are given in Table XI.6.

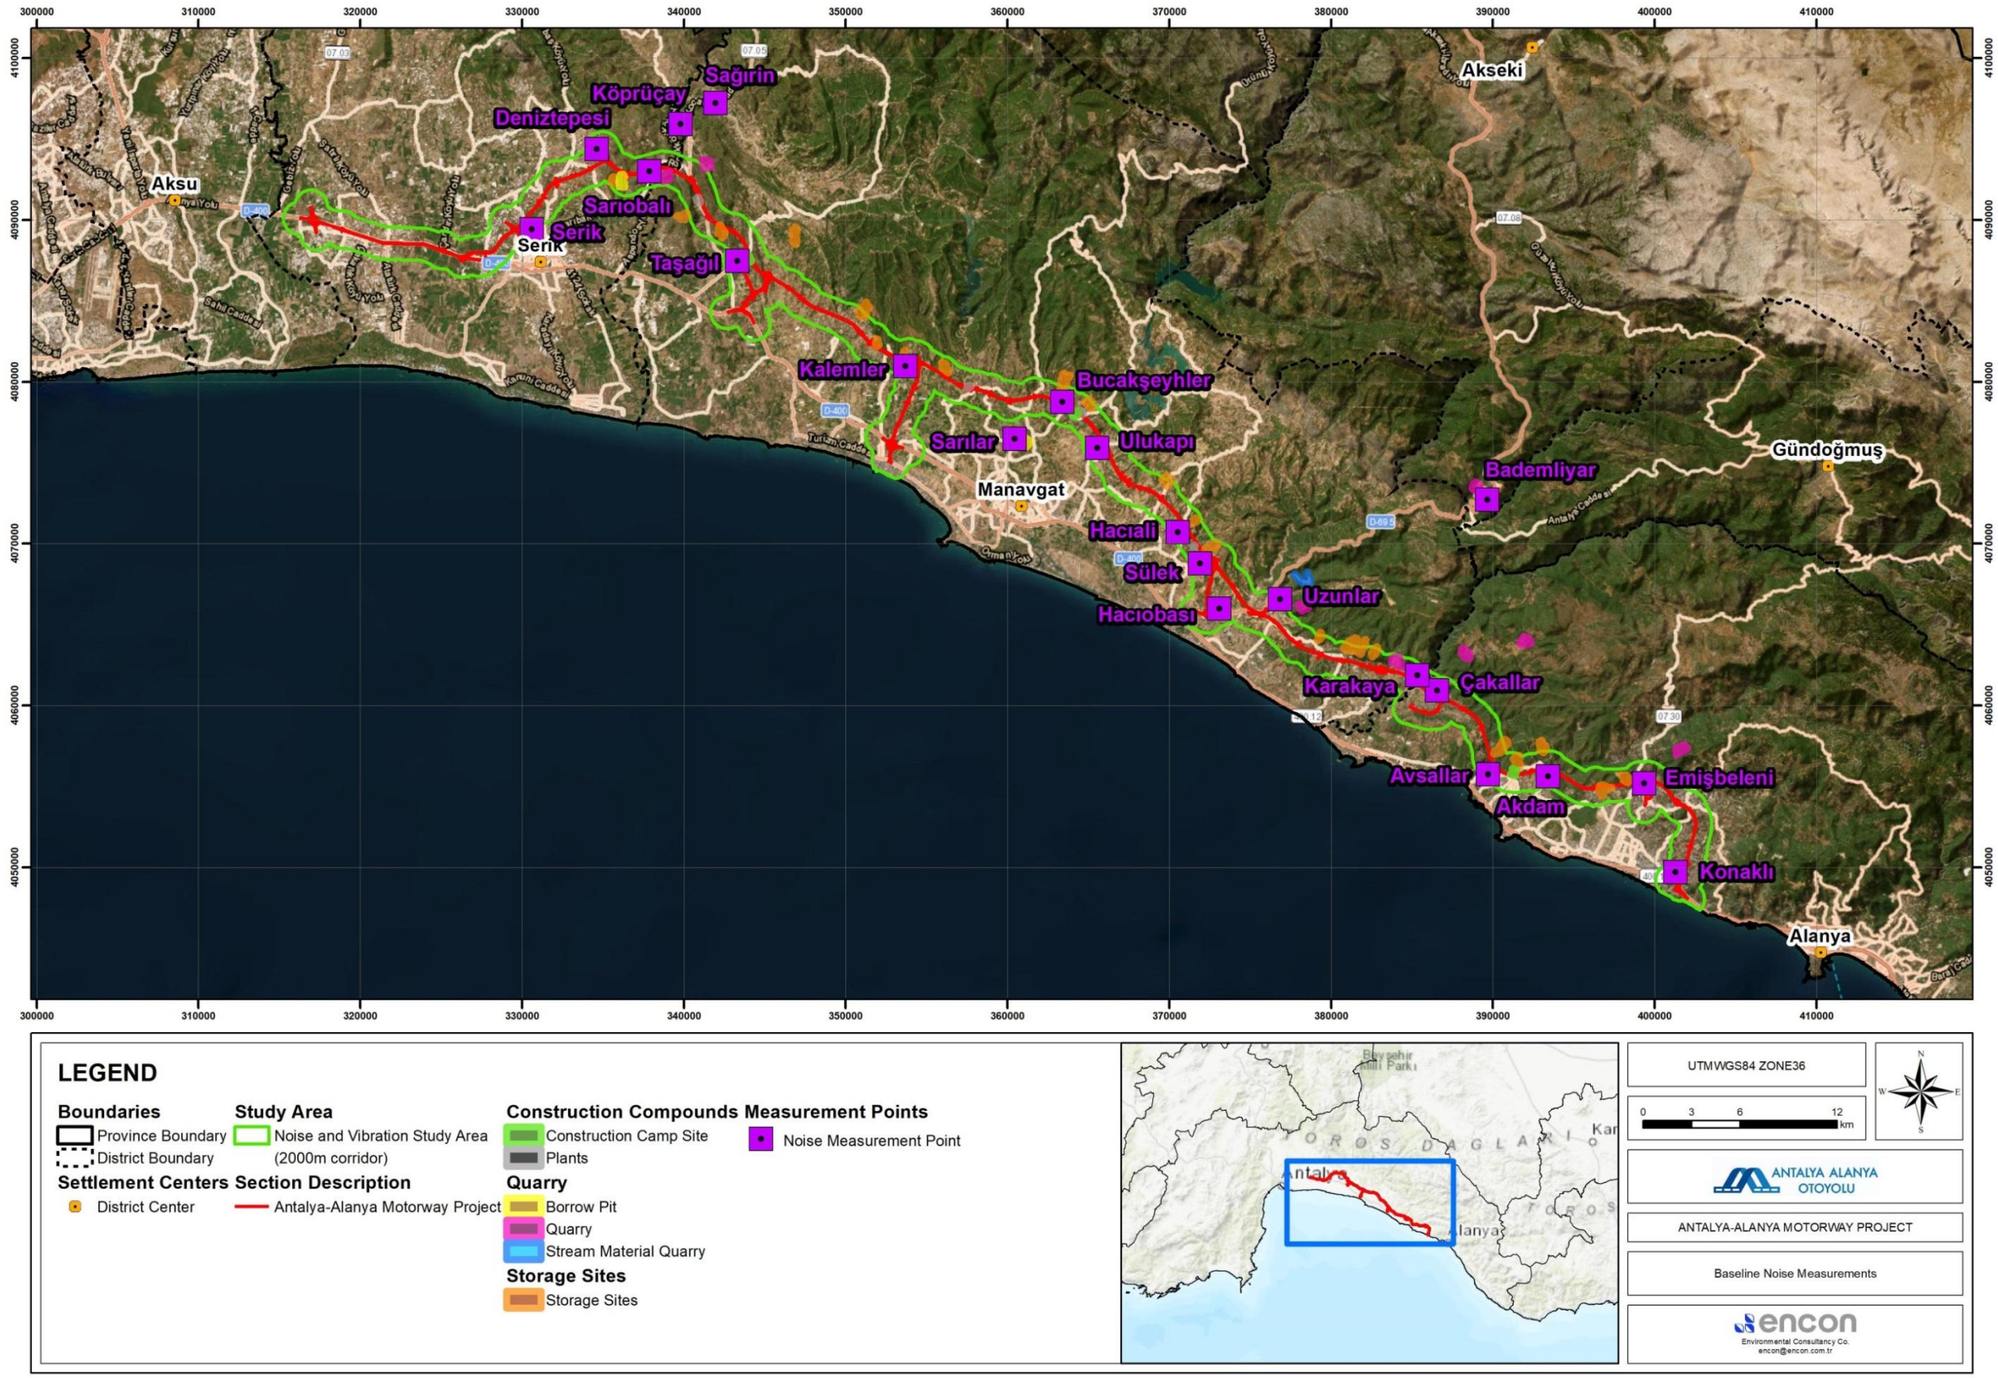

Figure XI.4 Baseline Noise Measurements

XI.1.3. Potential Impacts

Both land preparation and construction, and operation phase activities of the Project are expected to result in increases in noise levels, particularly in the vicinity of the Motorway route.

In order to evaluate the increase in noise levels in neighborhoods along the route, noise modeling was conducted using SoundPLAN V 9.1 (64-bit) software. The objectives of the modeling study are as follows:

- Estimate noise levels caused by construction activities related to the Project and prepare corresponding noise maps.
- Estimate noise levels during the operation of the Motorway and prepare corresponding noise maps.
- Determine whether noise levels at a specified location exceed limit values defined in relevant regulations and guidelines.
- Define mitigation measures to reduce noise levels to acceptable levels at specified limit exceeding locations.

The noise emissions for the motorway were calculated using data from the “Guide du bruit des transports terrestres, fascicule: prévision des niveaux sonores – CETUR 1980”, which is referenced in the French standard NMPB-Routes-96 (XPS 31-133). This methodology is recognized in the Réseau National des Experts en bruit des infrastructures de transport (RNEC) and is also compatible with the principles outlined in the EU Environmental Noise Directive (END).

The selection of the NMPB-Routes-96 method, rather than the CNOSSOS-EU: Road (2015/2021) model, was based on its continued acceptance in various national frameworks and its applicability to the project’s specific parameters. The RNEC guideline provides flexibility in allowing either NMPB-Routes-96 or CNOSSOS-EU methods, and in this case, the former was selected due to availability of input parameters and compatibility with existing datasets.

For motorway calculations:

- NMPB-Routes-96 / CETUR 1980 (as per French standard and endorsed by RNEC) or CNOSSOS-EU: Road (2015 or 2021) (as per EU END)

For industrial facilities:

- TS ISO 9613-2:2024-01, Acoustics – Attenuation of sound during propagation outdoors – Part 2: General method of calculation or CNOSSOS-EU: Industry (2015 or 2021)

Furthermore, the calculation height was taken as 4 meters, in accordance with the standard practice defined in both NMPB and CNOSSOS-EU frameworks. This height corresponds to the most exposed point on the building façade, which should be located at 4 ± 0.2 m above ground level, ensuring consistency with both directive requirements and modeling accuracy.

For the construction site and construction phase, TS ISO 9613 - 2: 2024-01 Acoustics - Attenuation of Sound as it Propagates Outside - Part 2: General Calculation Method was used.

Noise map calculations were performed according to the Noise Map Preparation Guide published by the Ministry of Environment, Urbanization and Climate Change. The modeling results will be evaluated according to the noise limit values for “industrial facilities, transportation resources” defined in the RENC (see Table XI.1), and the IFC noise limit value of 45 dB (A) at night (see Table XI.3).

XI.1.3.1. Land Preparation and Construction Phase

Noise modeling for the land preparation and construction phases was conducted by simulating the noise levels generated by construction machinery and equipment used during these activities. To represent the worst-case scenario, the maximum number of machinery and equipment was considered in the modeling studies. Noise intensity levels for each type of equipment were sourced from the SoundPlan software database. It is unrealistic to assume that all construction machinery and equipment planned to operate at the project site will run at full capacity. The primary reasons are the insufficient number of personnel and the physical impracticality of operating two different types of machinery in the same place at the same time due to workflow constraints. For this reason, a 50% operating percentage was used in the modeling. Additionally, the machinery and equipment to be utilized for road construction activities are planned to operate for 20 hours per day in two shifts. In contrast, the machinery and equipment to be used within the construction sites are expected to operate for 10 hours per day, also in two shifts.

Blasting Noise (Air Overpressure) Assessment

The noise impact from blasting activities has been evaluated in terms of air overpressure, which is a key parameter for blasting-induced noise. According to the Antalya–Alanya Motorway Project Blasting Excavation Pre-Design Report, Project Director Prof. Dr. Ali Kahriman (Mining Engineer), Graduate School, Explosives Engineering Master's Program Coordinator, Istanbul Okan University, Faculty of Engineering and Natural Sciences, a threshold of 140 dB is considered as the limit for air overpressure. Depending on the explosive charge, the distances at which this threshold value can be reached have been calculated. As shown in Table XI.8, the distance at which 140 dB air pressure can be reached varies between 18 m and 72 m, depending on the amount of explosive used. These results ensure that blasting operations are managed in a way that minimizes the potential noise and safety impacts on the environment and sensitive receivers (evaluated according to the 15 mm/s vibration limit). The blasting noise values represent the scenario calculated for 15 mm/s. At lower vibration velocities (for example, 5 mm/s or 2 mm/s), the explosive charge would be reduced or the distance to the receiver would increase, resulting in a lower amplitude of blasting noise.

The Peak Particle Velocity (PPV) is calculated using the following formula:

$$PPV = K \times SD^{-\beta} = K \times (R/W^{0.5})^{-\beta}$$

- PPV: Peak Particle Velocity (15 mm/s used for calculations)
- K: Ground constant
- β: Ground attenuation coefficient
- R: Distance from blast to receiver (m)

To calculate the allowable amount of explosives per delay (W), the equation is rearranged as follows:

$$W = \left(\frac{R}{\sqrt[\beta]{\frac{K}{PPV}}} \right)^2$$

The sound pressure level at a given distance is calculated as:

$$L(d) = L(d_0) - 20.\log 10\ (d/d_0)$$

- L(d) = sound pressure level (dB(A)) at distance d
- L(d0) = reference sound pressure level (dB(A)) at distance d0
- d0 = reference distance (m)
- d = target distance (m)

Table XI.8 Calculations based on the distance to the risk point for a vibration of 15 mm/s

Distance to Risk Point (m)	Max. Explosive Charge (kg/delay) [15 mm/s limit]	140 dB Air Overpressure Distance (m)
50	6.06	18
100	24.22	29
150	54.50	37
200	96.88	45
250	151.38	53
300	217.98	59
350	296.70	66
400	387.52	72

Calculations were carried out based on the worst-case scenario, with a maximum explosive charge of 387.52 kg per delay. The maximum charge weight per delay is expressed in TNT equivalent, and approximately 70% of the explosives consist of ammonium nitrate, which is common practice in the mining industry. The result of the maximum charge per delay (kg) is illustrated in Figure XI.5, while the detailed Blasting Noise Levels are provided in Table XI.9.

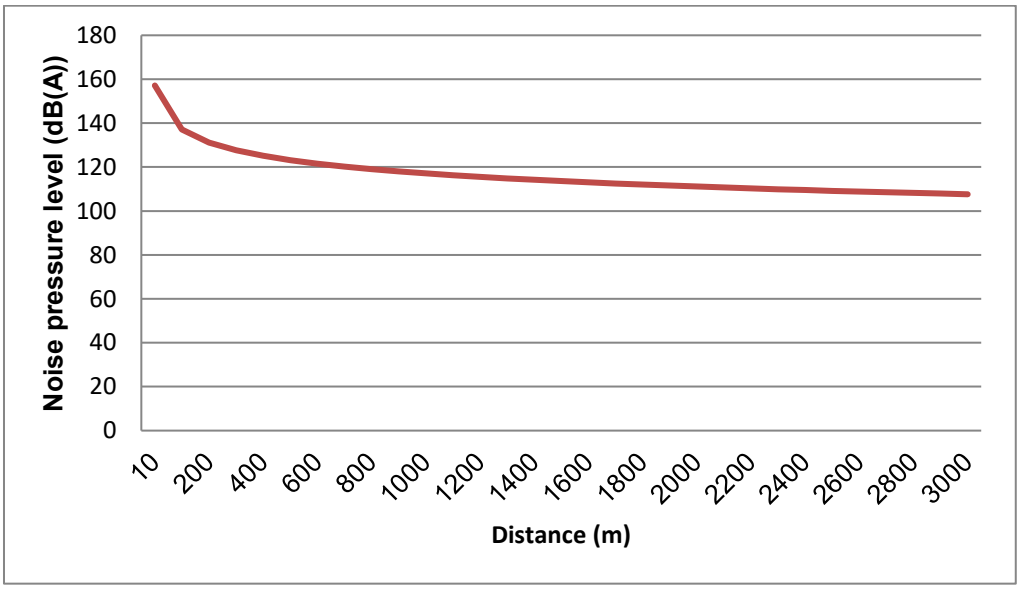

Figure XI.5 Noise Pressure Level Attenuation with Distance from Blasting Source

Table XI.9 Predicted Blasting Noise Levels

Charge Per Delay	30 m	100 m	500 m	600 m	1,000 m	1,500 m	2,000 m	3,000 m
387.52 kg	147.6	137.1	123.2	121.6	117.1	113.6	111.1	107.6
296.7 kg	146.8	136.4	122.4	120.8	116.4	112.9	110.4	106.8
217.98 kg	145.9	135.4	121.4	119.9	115.4	111.9	109.4	105.9
151.38 kg	144.9	134.5	120.5	118.9	114.5	111.0	108.5	104.9

54.5 kg	141.8	131.4	117.4	115.8	111.4	107.8	105.3	101.8
24.22 kg	139.7	129.2	115.3	113.7	109.2	105.7	103.2	99.7
6.06 kg	135.6	125.1	111.1	109.5	105.1	101.6	99.1	95.6

Prior to blasting operations, the sensitivity of nearby settlements and structures to noise and vibration will be assessed. All blasting operations will be conducted in accordance with the project's Blasting Management Plan. The noise from a blast can be quite high if the listener is within a few hundred meters of the blast. Airborne pressure waves, particularly the low-frequency component, can cause annoyance through both hearing and feeling at levels above peak values of around 140 dBA. However, at greater distances, it is generally perceived as a low rumble or "popping" sound lasting one or two seconds. If the wind is blowing away from the listener, the sound may not be heard. Certain atmospheric conditions, such as low cloud cover, can allow the sound waves to propagate over longer distances, resulting in a more noticeable "air blast" effect. The development and implementation of the Blasting Management Plan, combined with conducting blasts within pits and well below ground level, will minimize the impact of air blast noise. Aboveground blasting operations will not be conducted within a 100-meter radius of residential areas or neighborhoods if alternative construction methods are feasible.

Noise Modelling for Land Preparation and Construction Phase

During the noise impact assessment, virtual receiver points were defined within a calculation area covering approximately 3 kilometers along the construction zones of the project route, and extending up to 1 kilometer on both sides of the motorway corridor. These virtual receivers were positioned to both represent the baseline noise measurement locations and to ensure accurate modeling of noise propagation.

While developing the terrain model for the region, it was observed that building heights within the study area vary due to the project route passing through different zones. Although most buildings in the project area are one to two stories high, in residential complexes located within the project corridor, building heights can reach up to five stories.

List of maximum number machinery to be used in different sections of motorway are presented in Table XI.10.

Noise modeling for the construction phase was conducted using SoundPLAN software, with simulations performed at a height of 4 meters and using 10 x 10 meter grid structure. Noise levels observed in nearest receptors which are all classified with high sensitivities are presented in **Error! Reference source not found.** Table XI.6.

Table XI.10. Maximum Number of Construction Machinery

Type of Machinery	Number of Machinery	Sound Power Level dB(A)*
Excavator	51	105
Grader	5	100

Type of Machinery	Number of Machinery	Sound Power Level dB(A)*

Total	**472**	**126.47****

* Sound power levels are taken from the SoundPLAN library. Source :Bearbeitung: RWTÜV Anlagentechnik GmbH, Essen im Auftrag des Landesumweltamtes NRW, Essen 2000
** Total sound power level

The sound power levels of the machinery to be used at construction sites and for road construction activities have been calculated using the formula provided below.

$$Leq = \sum_{İ=1}^{n} 10*\log[1/n*(10^{Li/10}+.....+10^{Li/10})$$

n: Total Quantity
Li: Sound Power Level
Leq: Total Sound Power Level

Due to the fact that the project route traverses different regions, building heights within the project area exhibit variation. While the majority of structures are low-rise buildings ranging from 1 to 2 storeys,

certain public housing developments within the project corridor include buildings with heights of up to 5 storeys. The terrain model of the project area is illustrated in Figure XI.6 and Figure XI.7.

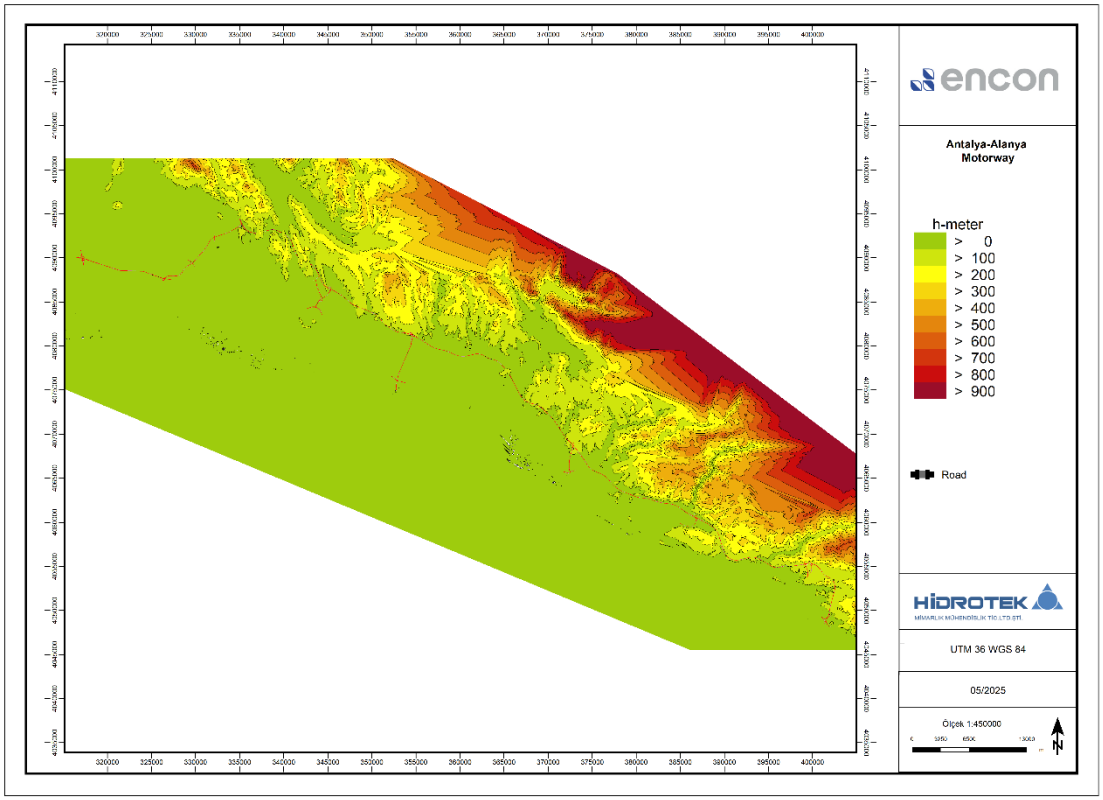

Figure XI.6 AAMP land model

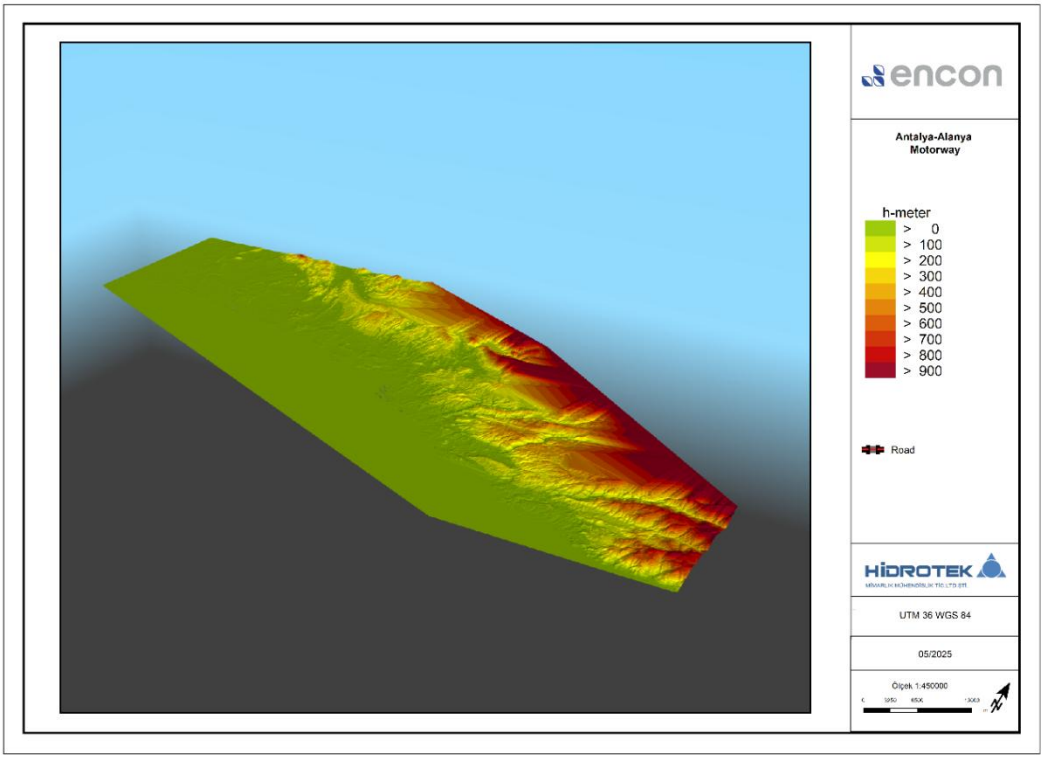

Figure XI.7 AAMP Land model 3D

Situation Assessment for Construction Sites and Motorway Construction Route

In the noise modelling study, land use classifications were taken into account, and it was specified that construction site activities would be carried out during daytime hours (07:00–19:00). Accordingly, all calculations were conducted based on this time frame. The impact assessment was performed by comparing the modelling results with the threshold values specified in the RENC.

The spatial distribution of construction site and motorway construction activities is presented in Figure XI.8, using Google Earth imagery. Noise distribution maps corresponding to Lgag (24-hour exposure) and Lday (07:00–19:00) are provided in Figure XI.14 through Figure XI.18. An example section based on these modelling results is presented herein, while detailed outputs and full modelling documentation are provided in Annex 7 Noise Modelling Report**.**

Figure XI.8 Construction Sites, Quarries and Motorway Route Map Sheets

During the construction phase, noise levels and affected areas along the motorway are illustrated in Figure XI.9 to Figure XI.13 as noise corridors in decibels. These maps depict the spatial distribution and intensity of noise generated by excavation, embankment, quarry operations, and transportation activities. The noise corridors help identify the maximum decibel levels that nearby settlements may be exposed to and support the planning of necessary mitigation measures.

*No additional contribution is considered for the areas marked with a dash (-).

According to the construction phase modelling results presented in Table XI.11, exceedances of the IFC standards (Background + 3 dBA) were observed only in Sarıabalı neighbourhood during both weekday and weekend assessments. Noise monitoring in Sarıabalı is recommended.

The modelling results also indicate that exceedances of the IFC standard occurred during nighttime on weekdays in Emişbeleni and Çakallar neighbourhoods, and during nighttime on weekends in Hacıobası neighbourhood. Based on these findings, it is recommended that construction activities, particularly during night hours, be limited; noise-generating operations be scheduled predominantly during daytime; and additional noise mitigation measures (e.g., barriers, equipment maintenance, use of quieter methods) be implemented where necessary. Other locations remained within IFC limits.

Several measures are recommended to reduce this increase in noise levels (see Section XI.1.4.1). These figures provide a spatial representation of predicted noise levels based on topography, building structures, source characteristics, and operational scenarios. The noise modelling methodology, input parameters (such as traffic volume, vehicle types, construction activities, etc.), and detailed information on the noise maps are provided in the Noise Modelling Report included in Annex 7.

The assessment of noise-related impacts has been carried out by evaluating the magnitude of impact and the sensitivity/value of the receptors/resources. The significance of impacts has been classified as high, medium, or low based on this evaluation. The criteria presented in Chapter IV (“ESIA Methodology”) have been used to determine the magnitude of impact, while the sensitivity/value levels of the receptors/resources have been assessed in accordance with the criteria summarized in Table XI.4. Based on the results of the noise modeling study, increases in baseline noise levels measured in settlements located near the motorway route were used to determine the impact magnitude. The outcome of this assessment is presented in Table XI.12.

Table XI.12. Sensitivity of Settlements to Noise along the Motorway Route

Receptor / Location	Sensitivity of the Receptor

Taşağıl	High (3)
Hacıali	Medium (2)
Deniztepesi	High (3)
Serik	Medium (2)

In the absence of mitigation measures, noise may occur, particularly in buildings located very close to construction areas based on worst-case estimates. However, it should be noted that all impacts related to the land preparation and construction phase will be intermittent and temporary (short-term and reversible) impacts for at most 3 years.

XI.1.3.2. Operation Phase

Similar to the land preparation and construction phases, noise impacts during the operation phase were assessed through a modelling study conducted using the SoundPLAN software. This assessment considered nearby settlements and sensitive receptors located along the motorway route. The predicted noise levels for daytime, evening, and nighttime periods were compared with the limit values defined in both the national Regulation on the Evaluation and Management of Environmental Noise (RENC) and the IFC Environmental, Health and Safety (EHS) Guidelines. The modelling results, together with existing baseline noise measurements, were evaluated against these standards, and appropriate mitigation measures were proposed where exceedances were identified.

The spatial distribution of motorway operation activities is presented in Figure XI.24, using Google Earth imagery. Noise distribution maps corresponding to Lgag (24-hour exposure) and Lday (07:00–19:00) are provided in Figure XI.25 through Figure XI.28. An example section based on these modelling results is presented herein, while detailed outputs and full modelling documentation are provided in Annex 7 Noise Modelling Report**.**

During the operation phase, noise levels caused by traffic are shown in Figure XI.19 to Figure XI.23 as noise corridors in decibels. The maps illustrate how noise varies with different traffic volumes and vehicle types, indicating the maximum decibel levels that nearby residential areas may experience. These figures provide a basis for implementing traffic management and noise reduction measures.

*No additional contribution is considered for the areas marked with a dash (-).

According to the operation phase modelling results presented in Table XI.13, the IFC standard (Background + 3 dBA) was exceeded during both daytime and nighttime on weekdays in Çakallar and Emişbeleni neighbourhoods. In Konaklı, Hacıobası, Bucakşeyhler, and Kalemler neighbourhoods, exceedances were observed during daytime on weekdays, with nighttime exceedances on weekends in Hacıobası neighbourhood.

In the Emişbeleni and Bucakşeyhler neighborhoods, the installation of noise barriers is recommended due to the exceedance of the IFC standard. In other neighborhoods where IFC limits are only slightly exceeded or limited to specific time periods, operational measures such as restricting construction activities during nighttime hours, regular maintenance of noise-generating equipment, using quieter methods, and shifting noise sources to daytime hours are recommended. (see Section XI.1.4.2).

Result

The noise emission impacts of the Project were evaluated using SoundPLAN V 9.1 (64-bit) software in accordance with RENC and IFC regulations, utilizing projected traffic data for 2040 to predict noise levels. Existing noise levels were measured at 21 locations along the motorway route and construction sites, with virtual receivers assigned to these points for noise calculations. During the motorway's construction phase, noise limit values were exceeded at the quarries and construction site in accordance with legislation. Furthermore, it is projected that noise limits are predicted to be exceeded in two regions after the motorway becomes operational. To mitigate these impacts, noise barriers have been proposed for the Bucakşeyhler and Emişbeleni sections, and ongoing monitoring is recommended in both areas moving forward.

Action Plan Recommendations

Based on the modeling results, afforestation is recommended as a primary measure to maintain noise levels within permissible limits. For effective noise mitigation, afforestation areas should extend at least 30 meters wide from the motorway, with the planting of dense, evergreen trees suitable for both winter and summer seasons. Tree species should be selected for their leaf properties to maximize noise absorption. Additionally, earthen embankments are proposed to provide elevation and act as noise barriers; these structures consist of raised earthworks reinforced with materials such as wood, concrete, steel nets, or woven grasses, which also allow for the planting of tree saplings and contribute aesthetically to the motorway environment. In locations where space is limited, conventional noise barriers may be installed. It is essential that background noise measurements be conducted in sensitive receptor areas during both construction and operation phases, with noise mitigation measures implemented only when noise levels exceed environmental limits. Continuous monitoring, evaluation, and timely implementation of corrective actions are therefore strongly advised.

An action plan has been developed for the Bucakşeyhler and Emişbeleni neighborhoods. Representative noise maps illustrating the conditions prior to the implementation of the action plan are presented in Figure XI.29 and Figure XI.30, in accordance with the Environmental Noise Directive and IFC guidelines. Detailed information on the noise modeling is provided in Annex 7.

Following the implementation of the action plan, changes in noise levels were evaluated in accordance with the Environmental Noise Directive and IFC guidelines; Bucakşeyhler neighbourhood was found to comply with IFC standards, while in Emişbeleni neighbourhood, noise barriers reduced levels but weekday exceedances of the IFC standards (Background + 3 dBA) were still observed. As the modelling was based on a worst-case scenario, noise levels are expected to decrease in the future as vehicles transition to electric.

XI.1.4. Mitigation Measures

The following subsection describes the actions and strategies designed to avoid, minimize or offset the potential adverse noise impacts of the Project.

XI.1.4.1. Land Preparation and Construction Phase

To ensure that the noise levels remain below national and international standards at the closest sensitive receptors to noise source, the following mitigation measures will be implemented:

- Equipment and machinery with lower sound power levels and noise-reduced models will be prioritized when possible and feasible.
- Newer and/or well-maintained vehicles, machinery and equipment will be preferred for procurement.
- Maintenance of construction machinery and equipment will be carried out regularly.
- Silencers will be installed on appropriate machinery and equipment, including mechanical plants machinery and construction vehicle exhausts.
- Portable barriers and acoustic enclosures will be installed around noise-generating stationary machinery, such as power generators, if necessary.
- Speed limits for construction vehicles will be enforced, particularly near sensitive areas.
- Traffic through residential areas will be minimized wherever possible. Dedicated site access roads will be constructed to reach Project components (campsites, the Motorway, quarries etc.) to avoid disturbances in residential areas when necessary.
- Noise monitoring will be conducted during the construction phase according to the Environmental Monitoring Plan (see Chapter XX “Environmental and Social Management System”). Noise levels in nearby settlements will be regularly monitored, and corrective measures will be taken immediately if any exceedance of national regulation and/or international standard limits is detected.
- Potentially affected buildings sensitive to nighttime disturbances will be identified prior to construction, and nighttime construction works will be limited accordingly.
- A community consultation program will be initiated to inform the nearby residents, businesses and the local community when noise impacts are anticipated according to construction schedule.
- Any noise related complaints received through the Project’s Grievance Mechanism will be assessed, and corrective actions will be implemented as necessary.
- Construction vehicles will not be permitted to keep engines running while waiting to enter the site or waiting on-site.
- Ancillary components in campsites, such as power generators, will be placed with consideration of potential noise disturbances.
- The Motorway alignment will be used for transportation whenever feasible.
- Roads used during the construction of the Motorway will be well maintained.
- Site personnel will be trained to carry out construction activities using noise-reduction methods.
- During the construction phase of the motorway in the Sarıabalı region, it was determined that the background noise levels increased by more than 3 dB(A) during daytime hours. It is therefore recommended that machinery and equipment to be used in this area be selected

based on low noise emission criteria, and that regular noise monitoring be conducted to ensure compliance with applicable noise limits.

XI.1.4.2. Operation Phase

- A green buffer strip will be formed at the service areas between the outer lane of the Motorway and the facilities. This strip will be properly planted (e.g. with shrubs that start growing from the base and are resistant to dust and gaseous emissions as well as noise) to act as a barrier against noise from the Motorway traffic.
- During the design phase of the Project, natural topography will be utilized as a noise buffer where possible.
- The Motorway route through residential areas will be minimized to the greatest extend feasible.
- Implementation of the action plans near the locations identified by the noise modeling study will be assessed in the later stages of project development. In addition, the installation of the noise barrier will be carried out after the approval of KGM, as detailed in the Environmental and Social Monitoring Plan (see Section XX), with the results of noise monitoring at the specified locations.
- Action plans will be developed and implemented in accordance with Technical Specifications of KGM where applicable.
- Any noise-related complaints received through the Project's Grievance Mechanism will be evaluated and corrective actions will be implemented as necessary.
- Semiannual noise measurements will be conducted at critical receptors determined by noise modelling throughout operation phase. If measurements approach the thresholds specified in RENC, noise barriers will be installed upon KGM approval. If noise barriers prove insufficient, additional measures such as landscaping will be implemented. Noise modelling and critical receptor assessments will be revised based on design changes or other mitigation measures applicable at critical locations.
- Based on the results of the Noise Modeling conducted as part of the Project scope, Noise barriers and earth embankment systems are considered as technically feasible mitigation options for Bucakşeyhler and Emişbeleni area. Aluminum noise barriers with high sound absorption capacity are recommended. An example of a sound-absorbing aluminum noise barrier is shown in Figure XI.35.

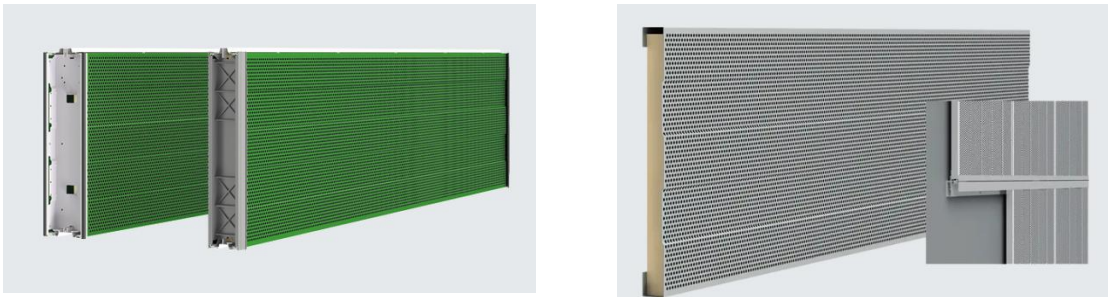

Figure XI.35 Sound-absorbing type aluminum noise barrier

XI.1.5. Summary of Assessment and Residual Impacts

The noise impact of the project was assessed using SoundPLAN V9.1 (64-bit) software, in line with the Environmental Noise Control Regulation and IFC guidelines. Noise predictions were based on traffic data projected for the year 2040. Existing noise levels were measured at 21 locations along the motorway and construction areas. Virtual receivers were assigned to these locations to estimate potential noise levels.

During the construction phase, measurements in the Sarıabalı area showed that noise levels exceeded the national daytime background limits by 3 dB(A), going beyond the allowed thresholds. The IFC's 55 dB(A) construction noise limit was also taken into account and compared with the measured values. Once the motorway is operation, noise levels are expected to exceed limits in two areas Bucakşeyhler and Emişbeleni due to traffic. Noise barriers are recommended for these locations, and ongoing noise monitoring will be necessary in the future.

In the Sarıabalı region, noise levels exceeding the permitted limits were recorded during the daytime, evening, and nighttime periods. Similarly, according to IFC guidelines, construction and motorway-related noise levels exceed the threshold values in Sarıabalı area.

In specific, two noise barriers are proposed at the sections of the settlements; namely Bucakşeyhler and Emişbeleni. The proposed artificial barriers would be 4.5 meters high and their length is proposed to be 3,750 meters in total (3,000 meters for Emişbeleni section and 750 meters for Bucakşeyhler section)

Details of the noise assessment and the significance of residual impacts are provided in Table XI.39. The Noise Level Report is included in Annex-7.

XI.2. Vibration

Vibration is a low-frequency disturbance producing physical movement in buildings and residents. Vibration can be measured in terms of Peak Particle Velocity, or PPV (i.e. the maximum speed of movement of a point in the ground during the passage of a source of vibration).

Construction activities can result in varying degrees of vibration depending on the equipment and methods used. Vibration from construction spreads through the ground and diminishes in strength with distance. Vibration can result in a disturbance in settlements close to the point of operation and may result in a risk of damage to structures in close vicinity. However, ground vibrations from construction activities rarely reach the levels that can damage structures but can achieve audible ranges in buildings close to the site. Construction activities which typically generate the most severe vibrations are blasting and piling operations.

Construction of the Motorway has the potential to cause vibration impacts as a result of activities such as piling, operation of vibratory equipment and blasting.

Operation of the Motorway has the potential to cause nuisance through vibration. Vibration arising from Motorway operation can be transmitted through the air or through the ground. Air vibration is generated by engines or exhaust of vehicles with frequencies of 50-100 Hz, while ground vibration is produced by interaction between vehicle wheels and road surface, observed in the 8-20 Hz frequency range (UK Highways Agency, 2011).

XI.2.1. Assessment Methodology and Data Sources

XI.2.1.1. Legal Framework

Turkish Legal Requirements

Regulation on Environmental Noise Control

According to RENC Annex-2 Article 12, vibration standards defined in Table 3 for the limit values of ground vibrations caused by blasting in mines, quarries and similar areas cannot be exceeded. Table 4 of RENC Annex-2 presents the maximum permissible values of ground vibrations generated by railway and road transport vehicles, workplaces, and industrial facilities in the nearest structure and ground vibrations generated by machinery and equipment inside the building. According to Article 14 of RENC Annex-2, the limit values of ground vibrations caused by pile driving and similar vibration-generating operations in construction and construction machinery outside the nearest structure should meet the limit values in Table 5.

Maximum permissible vibration for sensitive and highly sensitive areas due to blasting in mines, quarries, etc. is presented in Table XI.15. The maximum permissible values of ground vibrations caused by railway and road transport vehicles, workplaces and industrial facilities in the nearest building and ground vibrations caused by machinery and equipment inside the building are presented in Table XI.16. The maximum permissible vibration for sensitive and highly sensitive areas caused by pile driving and other vibration-inducing activities and heavy construction vehicles during construction is presented in Table XI.17.

Table XI.15. Vibration Limits for Quarries

	Structure Type	Maximum Vibration Velocity at the Foundation of Buildings, (mm/s) (according to frequency, f=Hz)			On the top floor[2] slab for all frequencies
		f= 1-10	f=10-50	f=50-100[1]	
1	Industrial buildings	20	40	50	40
2	Durable structures such as houses, bricks, and concrete	5	15	20	15
3	Buildings, historical and natural structures that are sensitive to vibration and are not included in items 1 and 2 [3]	2	8	10	8

(1): For frequencies greater than 100 cycles/sec, a large vibration level is permissible.
(2): For buildings with more than one floor, measurements should be taken both at the foundation of the building and at the slab of the top floor.
(3): These limit values determined for historical and natural structures may be restricted by precise, comprehensive vibration measurements and scientific studies to be carried out on-site.

Table XI.16. Vibration Limits for Ground Vibrations Caused by Road Transport Vehicles, Workplaces and Industrial Facilities in the Nearest Structure

	Frequency of Vibration (Hz)	Maximum Allowed Vibration Speed (rms value (mm/s))
Residential buildings	1[1]	1.5
	8-100	0.3
In the offices	1[2]	3.5
	8-100	0.6
Historical and natural structures[4]	1[3]	0.8
	8-100	0.1

(1): The maximum permissible vibration speed is determined according to the vibration frequency in the graph drawn logarithmically with the specified values. For example, between 1 Hz-8 Hz, it decreases linearly from 1.5 mm/sec to 0.3 mm/sec in the logarithmic graph.
(2): The highest permissible vibration speed is determined according to the vibration frequency in the graph drawn logarithmically with the specified values. For example, between 1 Hz-8 Hz, it decreases linearly from 3.5 mm/sec to 0.6 mm/sec in the logarithmic graph.
(3): The highest permissible vibration speed is determined according to the vibration frequency in the graph drawn logarithmically with the specified values. For example, between 1 Hz-8 Hz, it decreases linearly from 0.8 mm/sec to 0.1 mm/sec in the logarithmic graph.
(4): These limit values determined for historical and natural structures can be limited by precise, comprehensive vibration measurements and related scientific studies to be carried out on site.

Table XI.17. Vibration Limits for Construction

Area/Receptor	Maximum Allowed Vibration (Peak Particle Velocity in-mm/s)[1]	
	Continuous Vibration	Discontinuous Vibration
Residential Areas	5	10
Commercial Areas	15	30
Historical and Natural Structures[2]	2	5

(1): Frequency: 1-80 Hz.
(2): These limit values determined for historical and natural structures may be limited by precise, comprehensive vibration measurements and scientific studies to be carried out on-site.

Damage Classification

Blast-induced damage criteria developed by various researchers have been implemented to varying degrees. These studies generally fall into two main categories:

i. Identification, measurement, and analysis of ground vibrations and air overpressure resulting from blasting;
ii. Definition of structural damage thresholds and correlation of these thresholds with post-blast parameters to enable appropriate blast design.

Among the commonly referenced and widely accepted standards—due to their use of similar parameters—the three most prominent are:

- The Regulation on the Control of Environmental Noise by the Republic of Türkiye Ministry of Environment, Urbanization and Climate Change,
- The U.S. Bureau of Mines (USBM) Damage Criteria, and
- The German Standard DIN 4150.

The damage classification proposed by the USBM (see Table XI.18) divides damage into three categories: Threshold Damage, Minor Damage, and Major Damage. Threshold Damage is considered non-structural and cosmetic in nature.

Table XI.18 Damage Classification[1]

Damage Category	Damage Description
Threshold Damage (Initial Damage)	Cracking and blistering of paint; small plaster cracks at the joints of structural elements; extension of pre-existing cracks.
Minor Damage	Blistering and detachment of plaster; hairline to 3 mm wide cracks in partition walls and around window frames in stone masonry; mortar loss due to loosened joints.
Major Damage	Wide cracks in walls; cracks in arches; weakening of load-bearing structural elements; falling of stones or bricks in masonry structures (e.g., chimneys); reduction in load-bearing capacity.

Although Minor Damage is relatively more visually disturbing, it does not affect the structural strength or the load-bearing capacity of building elements. The only type of damage that causes permanent deformation and compromises the structural integrity of a building is classified as Major Damage. In the analyses and evaluations to be carried out in the later sections of this report, the term “damage” will be used in the sense of “Threshold Damage”.

On the other hand, Table XI.19 presents safe vibration levels that are not expected to cause damage in residential-type structures, categorized by building types. The values provided correspond to vibration levels that are not expected to induce cracks in the load-bearing elements of buildings. These thresholds are based on the assumptions that the buildings are constructed on properly engineered foundations, are no more than two stories high, and that the ground vibrations are short-term (lasting only a few seconds) and induced by blasting.

The limit values in Table XI.19 have been set lower than the threshold levels observed to cause damage in on-site measurements and observations conducted in the United States.

[1] According to the Antalya–Alanya Motorway Project Blasting Excavation Pre-Design Report, Project Director Prof. Dr. Ali Kahriman (Mining Engineer), Graduate School, Explosives Engineering Master’s Program Coordinator, Istanbul Okan University, Faculty of Engineering and Natural Sciences

Table XI.19 Maximum Safe Peak Particle Velocity (PPV) Levels for Different Building Types[2]

Building Type	Low Frequency (< 40 Hz)	High Frequency (> 40 Hz)
Modern Houses	19.0	50.8
Older Structures (with Timber Elements)	12.7	50.8

The values presented in Table XI.19 are based on the assumption that the probability of superficial cracking does not exceed 5%, meaning they provide a 95% confidence level that such cracks will not occur. Nevertheless, an alternative evaluation criterion that accounts more precisely for frequency variations is presented in Figure XI.36.

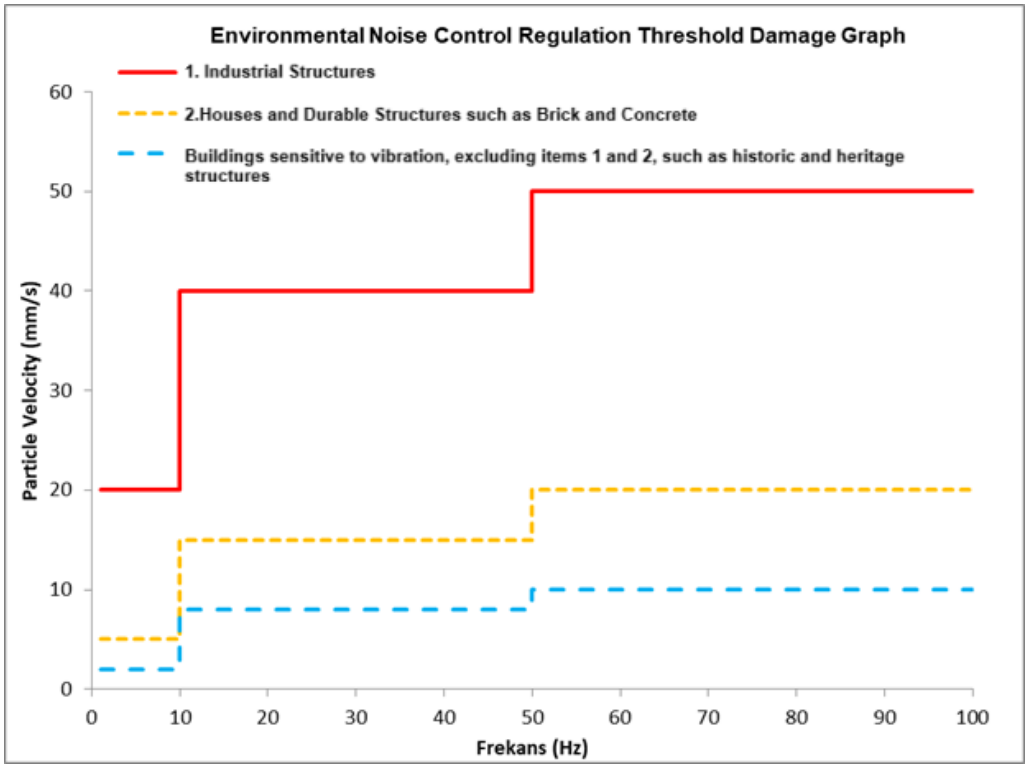

Figure XI.36 Threshold Damage Limit Values According to the Regulation of the Republic of Türkiye Ministry of Environment, Urbanization and Climate Change

IFC Standards

IFC Environmental, Health and Safety Guideline for Construction Materials Extraction state that the most significant vibration emissions are usually associated with blasting during material extraction and suggest techniques to minimize and control vibration impacts. IFC guidelines do not define any standards for vibration.

Significance Criteria

The significance criteria for the impacts regarding vibration will be determined, as high, medium or low, based on the evaluation of the magnitude of impact and sensitivity/value of the receptors/resources.

[2] According to the Antalya–Alanya Motorway Project Blasting Excavation Pre-Design Report, Project Director Prof. Dr. Ali Kahriman (Mining Engineer), Graduate School, Explosives Engineering Master's Program Coordinator, Istanbul Okan University, Faculty of Engineering and Natural Sciences

The criteria previously presented in Chapter IV ("ESIA Methodology") will be used for the determination of the magnitude of impacts, while sensitivity/value criteria to be used in the scope of impact assessment is summarized in Table XI.20.

Table XI.20. Criteria for Sensitivity/Value of Resource/Receptor

Ecosystem Component	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Residential Areas*	Neighborhood/village part of it (>20)	More than few number (10-20) of residential buildings	Few (1-10) residential buildings

** The level of sensitivity in public places such as health institutions, places of worship, hotels, etc. will increase by one degree for each existing institution/business.*

XI.2.2. Baseline Conditions

Baseline conditions regarding vibration indicate that, currently, no significant source was identified to cause vibration for the Project. Based on the assessments and measurements conducted, no significant sources of vibration have been identified within the Project area or its surroundings. This indicates that, under current baseline conditions, there are no environmental or structural concerns related to vibration. In other words, the existing vibration levels remain within natural background levels, and no notable human-made or mechanical sources contributing to elevated vibration levels have been observed.

XI.2.3. Potential Impacts

XI.2.3.1. Land Preparation and Construction Phase

Land preparation and construction phase of the Project has the potential to cause vibration impacts as a result of activities such as heavy vehicle movement, piling, excavation, heavy earthworks, operation of vibratory equipment, demolition, and blasting.

The operation of heavy vehicles during construction works is expected to impact specific locations for relatively short periods. The major concern regarding construction-related vibration is the potential for structural damage to nearby buildings. In addition to this, disturbances to residents in the immediate vicinity are also another primary concern.

The Construction Noise and Vibration Guideline (NSW Government, Transport, Roads and Maritime Services, 2016) recommends minimum working distances for vibratory construction equipment from sensitive receptors (see Table XI.21). The minimum working distances vary according to particular equipment types and also local geotechnical conditions.

Based on the Transportation and Construction Vibration Guidance Manual by Caltrans[3], Table XI.22 outlines the recommended "n" values for different soil types when assessing the vibrations produced by construction equipment such as pile drivers, bulldozers, and cranes. These values help to determine the potential impact of vibration levels on nearby structures and the surrounding environment during construction activities.

[3] https://dot.ca.gov/-/media/dot-media/programs/environmental-analysis/documents/env/tcvgm-apr2020-a11y.pdf

Table XI.21. Recommended Minimum Working Distances for Vibratory Equipment from Sensitive Receptor

Equipment	Description	Minimum Working Distance	
		Cosmetic Damage	Human Response
Vibratory Roller	<50 kN (typically 1-2 tons)	5 m	15 m to 20 m
	<100 kN (typically 2-4 tons)	6 m	20 m
	<200 kN (typically 4-6 tons)	12 m	40 m
	<300 kN (typically 7-13 tons)	15 m	100 m
	<300 kN (typically 13-18 tons)	20 m	100 m
	<300 kN (>18 tons)	25 m	100 m
Small Hydraulic Hammer	(300 kg - 5 to 12t excavator)	2 m	7 m
Medium Hydraulic Hammer	(900 kg – 12 to 18t excavator)	7 m	23 m
Large Hydraulic Hammer	(1600 kg – 18 to 34t excavator)	22 m	73 m
Vibratory Pile Driver	Sheet piles	2 m to 20 m	20 m
Pile Boring	≤ 800 mm	2 m	4 m
Jackhammer	Hand held	1 m	2 m

Table XI.22 Measured and Suggested "n" Values Based on Soil Class for drilling

Class	Soil Description	Characteristics	Measured "n" *(Woods & Jedele)*	Suggested "n"
I	Weak or Soft Soils	Loose soils, dry or partially saturated peat, muck, mud, loose beach or dune sand, recently plowed ground, soft spongy forest/jungle floor, organic soils, topsoil, *(Easily penetrated by shovel)*	Data not available	**1,4**
II	Competent Soils	Most sands, sandy clays, silty clays, gravel, silts, weathered rock, *(Can be dug with shovel)*	**1,5**	**1,3**
III	Hard Soils	Dense compacted sand, dry consolidated clay, consolidated glacial till, some exposed rock, *(Cannot be dug with shovel; requires pick to break up)*	**1,1**	**1,1**
IV	Hard, Competent Rock	Bedrock, freshly exposed hard rock, *(Difficult to break with hammer)*	Data not available	**1**

Vibration caused by Drilling Rigs

Drilling rigs will be used at various locations along the project route, generating vibrations that may affect nearby structures, infrastructure, and sensitive receptors. The intensity of these vibrations depends on the type of equipment, operational methods, local soil conditions, and the distance from the vibration source to receptors.

$$PPVEquipment = PPVRef * (25/D)^n \quad (1)$$

- PPV Equipment: the predicted peak particle velocity at the receiver (in in/sec)

- PPV Ref PPV Ref: is the reference PPV value for the drilling rig measured at 25 ft (in in/sec),
- D: the distance from the vibration source to the receptor (in ft),
- n: Attenuation rate exponent based on soil class (based on Table XI.22)

Vibration levels will be estimated using recognized methods that consider equipment vibration characteristics and site-specific attenuation factors derived from geotechnical data and receptor proximity. Reference vibration values for the equipment will be sourced from manufacturer data or prior measurements, and where necessary, field monitoring will be conducted to validate predicted levels.

Vibration Due to Drilling and Excavating Operations

Drilling operations, particularly those involving the use of high-capacity mechanical rigs, can generate low-level ground vibrations. While these vibrations are significantly lower than those produced by blasting, they are still subject to evaluation especially when activities are carried out near sensitive structures or environments.

The PPVRef has been established based on the performance data of the drilling rigs and bulldozers/excavators intended for use during the works. Considering the geological context, where the material being drilled is classified as hard, competent rock, a vibration attenuation constant of n = 1 has been applied. Based on these parameters, the reference Peak Particle Velocity is determined as 0.089 inch/s at 25 feet.

Using standard propagation models and using Equation 1, after coverting PPV for drilling rigs from in/sec to mm/s, the predicted vibration level at a distance of 10 meters is calculated to be approximately 1.72 mm/s.This value falls below the threshold of 2 mm/s according to Table XI.17, which is commonly recognized as the continuous vibrations limit for potential structural or environmental impact (Table XI.24). Therefore, the vibrations generated by the drilling operations are expected to remain within acceptable limits and are not anticipated to cause any adverse effects on surrounding assets or infrastructure shown on Figure XI.37.

Table XI.23 Calculations based on the distance to the risk point for of Drilling-Induced Vibration.

Distance (m)	PPV (mm/s)
5	3.45
8.65	1.99
10	1.72
20	0.86
30	0.57
50	0.34
60	0.29
80	0.22
100	0.17
150	0.11
300	0.06

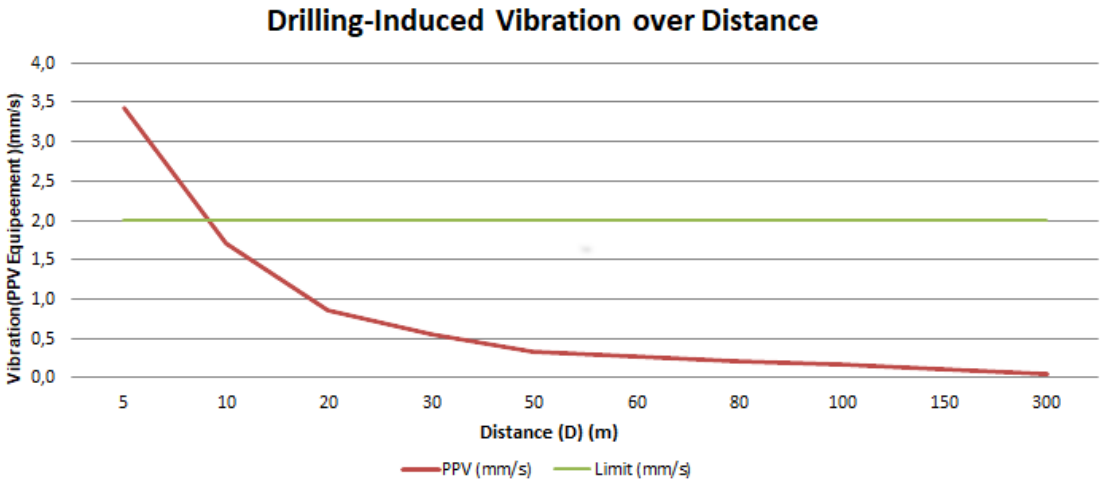

Figure XI.37 Area of effect of Drilling-Induced Vibration over Distance

Blasting preliminary design models to be applied in all types of excavations

According to the Regulation on Environmental Noise Control, the allowable particle velocity thresholds for potential damage on residential receptors and cultural heritage areas are set at 15 mm/s and 8 mm/s respectively for blasting activities in quarries and for potential damage on residential receptors and cultural heritage areas are set at 10 mm/s and 5 mm/s respectively for blasting activities in tunnels and cut-and-foundation. The maximum amount of explosives per delay that can be used without exceeding this threshold has been calculated using the equation PPV = K × SD^(-β), and the results are presented in Table XI.32**Error! Reference source not found.**. An example of the calculation steps used to create the table is provided below:

$$PPV = K \times SD^{-\beta} = K \times (R/W^{0.5})^{-\beta} \qquad (2)$$

To calculate the allowable amount of explosives per delay (W), the Peak Particle Velocity equation is rearranged as follows:

$$PPV = K * \left(\frac{R}{\sqrt{W}}\right)^{-\beta} <=> W = \left(\frac{R}{\sqrt[\beta]{\frac{K}{PPV}}}\right)^{2} <=> D = \sqrt{W} * \left(\frac{K}{PPV}\right)^{1/\beta} \qquad (3)$$

- PPV: Peak Particle Velocity (mm/s)
- K: Ground constant
- β: Ground attenuation coefficient
- R: Distance (m)

For the Antalya – Alanya Motorway Project, bench blasting using the mini-bench method will be implemented for cut and foundation excavations, considering site-specific conditions. The maximum charge per delay for different distances is presented in Table XI.32**Error! Reference source not found.**. Blasting geometry will be designed with variable bench heights depending on the distance to sensitive receptors.

According to the Antalya–Alanya Motorway Project Blasting Excavation Pre-Design Report, Project Director Prof. Dr. Ali Kahriman (Mining Engineer), Graduate School, Explosives Engineering Master's Program Coordinator, Istanbul Okan University, Faculty of Engineering and Natural Sciences, the main explosive will be ANFO or its equivalents, initiated preferably with non-electric delay systems. In general, 89 mm diameter boreholes with ANFO are planned; for benches shorter than 5 m, 76 mm diameter boreholes are recommended. Design parameters for both diameters are provided in Table XI.24, and two of the proposed bench blasting preliminary design models are shown on the sample plan and section in Figure XI.38, Figure XI.39, and Figure XI.40.

For the maximum allowable explosive amounts per delay, the most conservative values (K: 1884.9 and β: 1.605) are those from the vibration prediction equation developed by Kahriman et al. (2019) for the limestone rock units in Kepez District, Antalya. For safety reasons, these values have been adopted within the risk analysis framework.

Within this study, blasting operations must comply with the allowable explosive amounts per delay based on the appropriate vibration propagation equation and the distance to risk structures.

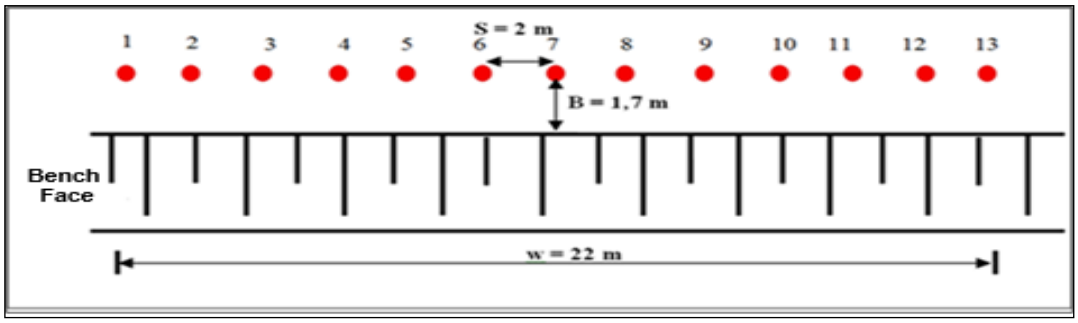

Figure XI.38 Proposed mini-step blasting preliminary design model (on Plan)

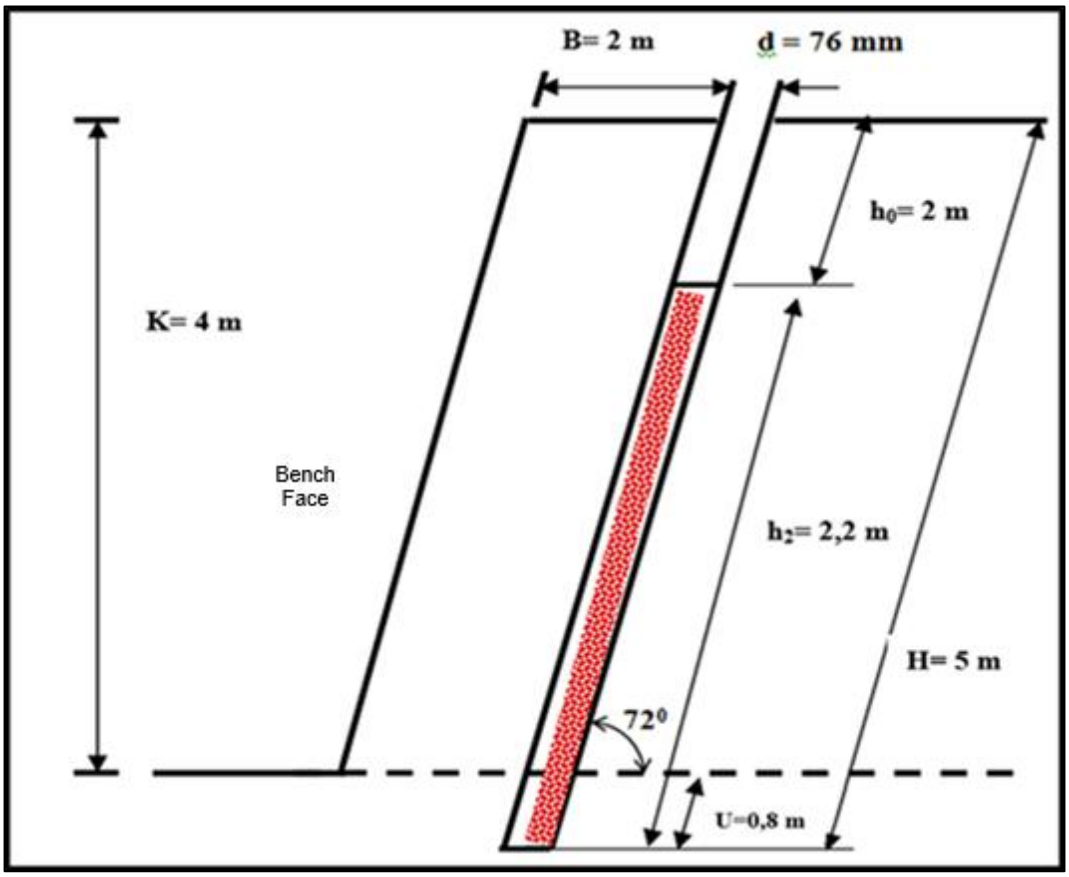

Figure XI.39 Proposed mini-step blasting preliminary design model (on Section)

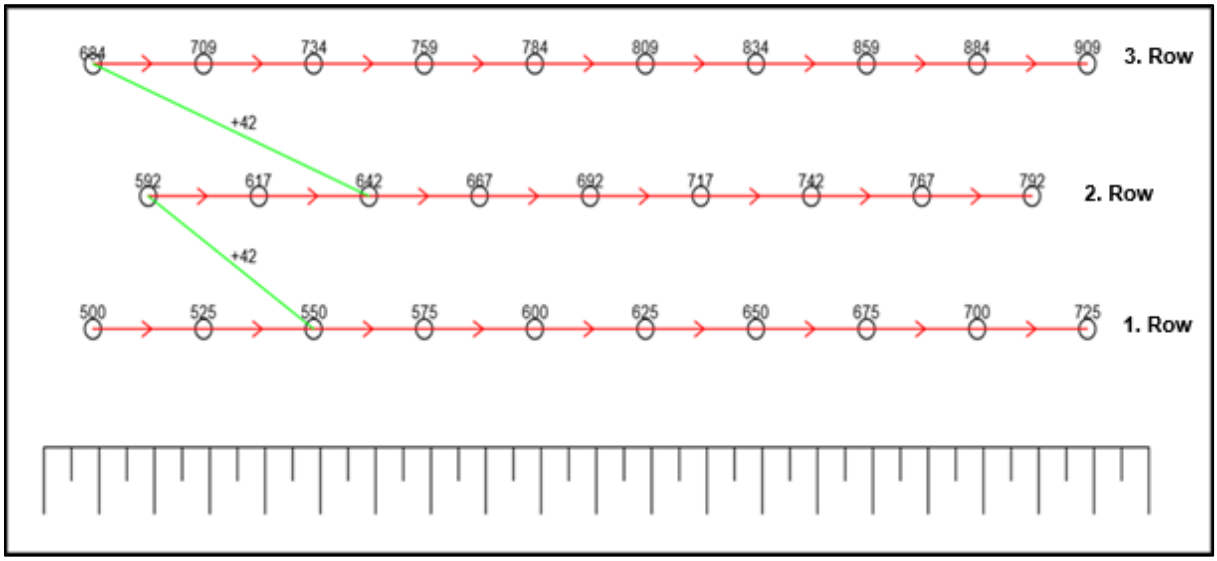

Figure XI.40 Example of a 3-row sample connection pattern with a delay of 500 ms within hole, 25 ms between holes in the same row, 42 ms between rows

In shots with two or more rows, connections shall be made between the rows using a delay element. In the inter-row transition, the delay will be planned in such a way that the holes in the back

row will not be blown before the holes in the front row are blown. A sample connection model is shown in Figure XI.40.

Table XI.24 Proposed Mini-Step Blasting Pre-Design Models

Bench Height K (m)	**3**	**4**	**5**	**6**	**7**	**8**	**9**	**10**
Hole Diameter d (mm)	76	89	76	89	76	89	76	89
Hole Length H (m)	3.8	4.2	5.0	5.2	6.2	6.2	7.1	7.1
Burden Thickness B (m)	1.7	2.4	2.0	2.5	2.25	2.7	2.2	2.7
Spacing Between Holes S (m)	2	2.6	2.5	2.75	2.6	3.0	2.7	3.3
Stemming h_0 (m)	1.7	2.4	2.0	2.5	2.25	2.7	2.2	2.7
Charge Density lb (kg/m)	3.6	5.0	3.6	5.0	3.6	5.0	3.6	5.0
Charge Quantity Q (kg)	7.56	9.0	10.8	13.5	14.22	17.5	17.64	22
Specific Drilling b (m/m^3)	0.37	0.22	0.25	0.19	0.21	0.15	0.2	0.13
Specific Charge q (kg/m^3)	0.74	0.48	0.54	0.5	0.49	0.43	0.49	0.41

For blasts near sensitive structures with bench heights over 5 meters, the staged charging method is recommended to reduce the charge per delay. This involves in-hole stemming and detonating different segments of the hole with separate delays, requiring an electronic initiation system. Parameters for the 10-meter bench are provided in Table XI.25, with a sample borehole section in Figure XI.41 and the delay layout shown in Figure XI.42.

Table XI.25 Parameters of the 2-stage blasting model to be applied when the step length is 10 meters

Bench Height K (m)	**10**
Hole Diameter d (mm)	76
Hole Length H (m)	11
Burden Thickness B (m)	2.3
Spacing Between Holes S (m)	2.7
Charge Density lb (kg/m)	4.0

Blasting Preliminary Design Models for Tunnel Excavations

Within the scope of the "Antalya – Alanya Motorway Project," tunnel excavations are planned at five different locations. The start and end kilometer points, along with the lengths of these tunnels, are provided in Table XI.26.

Table XI.26Tunnels planned to be constructed under the Project

Tunnel Name		Start Km	End Km	Tunnel Lenght (m)
T1 Tüneli	Left Tube	54+327	55+376	1,049
	Right Tube	54+311	55+378	1,065
T2 Tüneli	Left Tube	57+366	57+898	532
	Right Tube	57+386	57+985	597
T3 Tüneli	Left Tube	60+935	62+477	1,542
	Right Tube	60+958	62+477	1,519
T4 Tüneli	Left Tube	70+131	70+475	344
	Right Tube	70+131	70+475	344
T5 Tüneli	Left Tube	88+679	89+544	865
	Right Tube	88+671	89+544	873

The Project plans to construct excavations based on two different tunnel cross-section types: arched invert and flat invert. Visuals of these cross-sections are shown in Figure XI.43 and Figure XI.44, respectively.

Upon examining Figure XI.43 and Figure XI.44, the upper half geometries of both cross-sections are similar, while the lower halves vary. Therefore, a blasting design has been developed for the arched invert type cross-section shown in Figure XI.43, covering the upper half, lower half, and invert excavations. The upper half blasting design can be commonly applied to both cross-section types.

Excavation stages for the arched invert tunnel, with a total cross-sectional area of approximately 156 m², are illustrated in Figure XI.45. According to this plan, the upper half is excavated first, followed by the lower half, and finally the invert section.

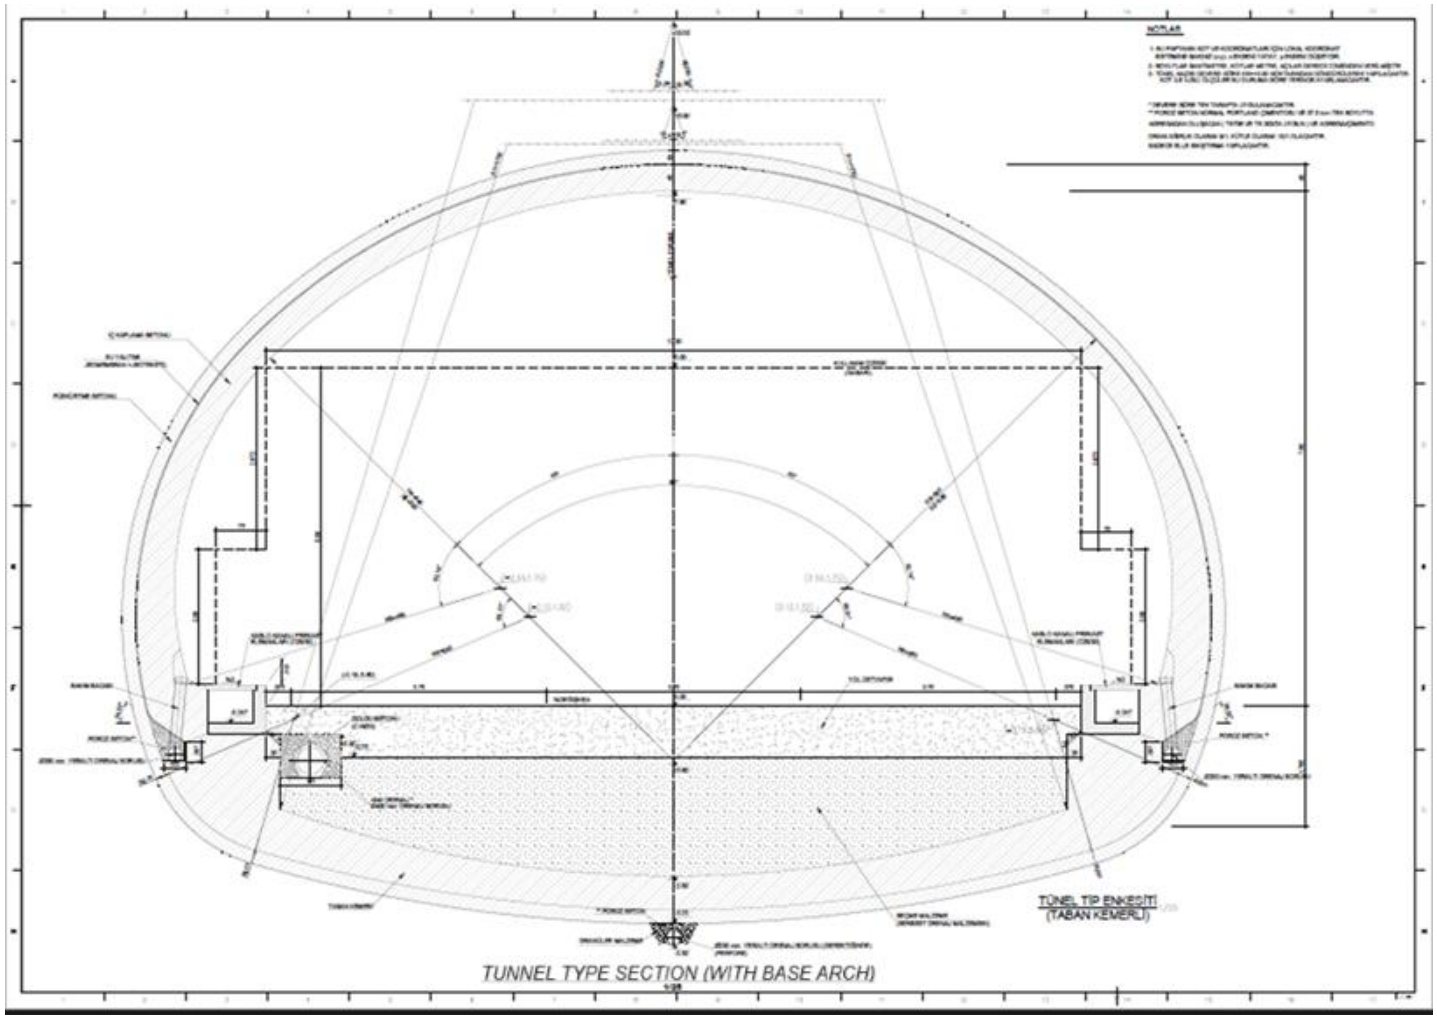

Figure XI.43 base-arched tunnel type cross-section

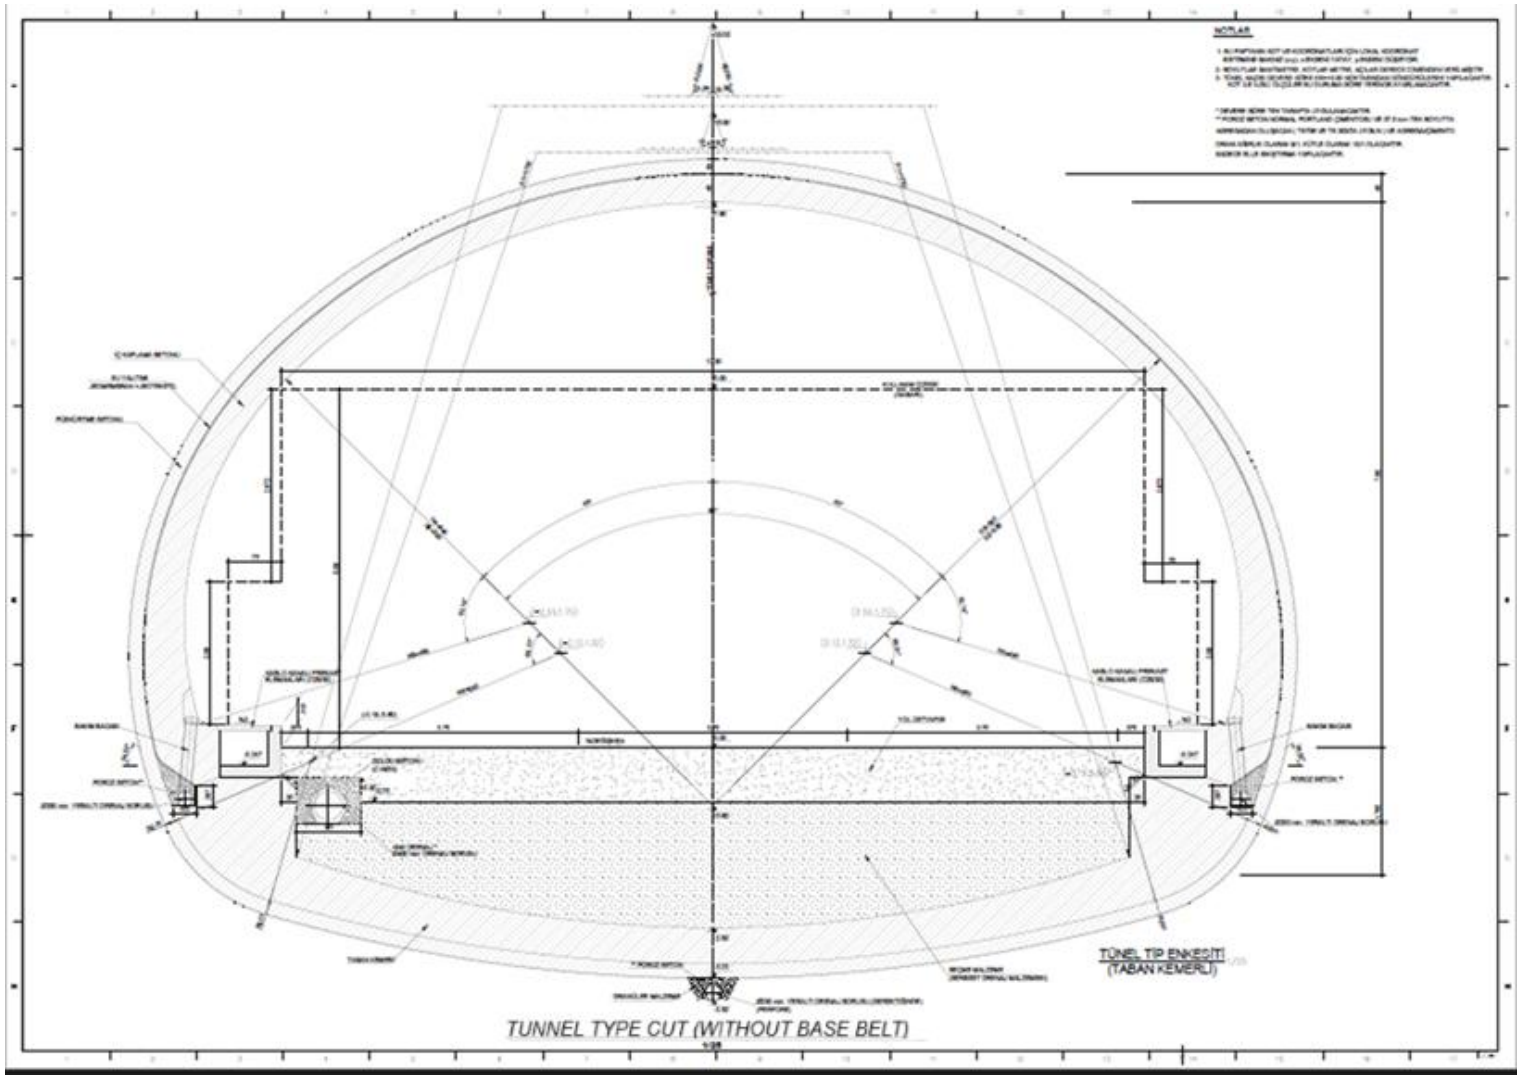

Figure XI.44 Flat-bottom tunnel cross-section

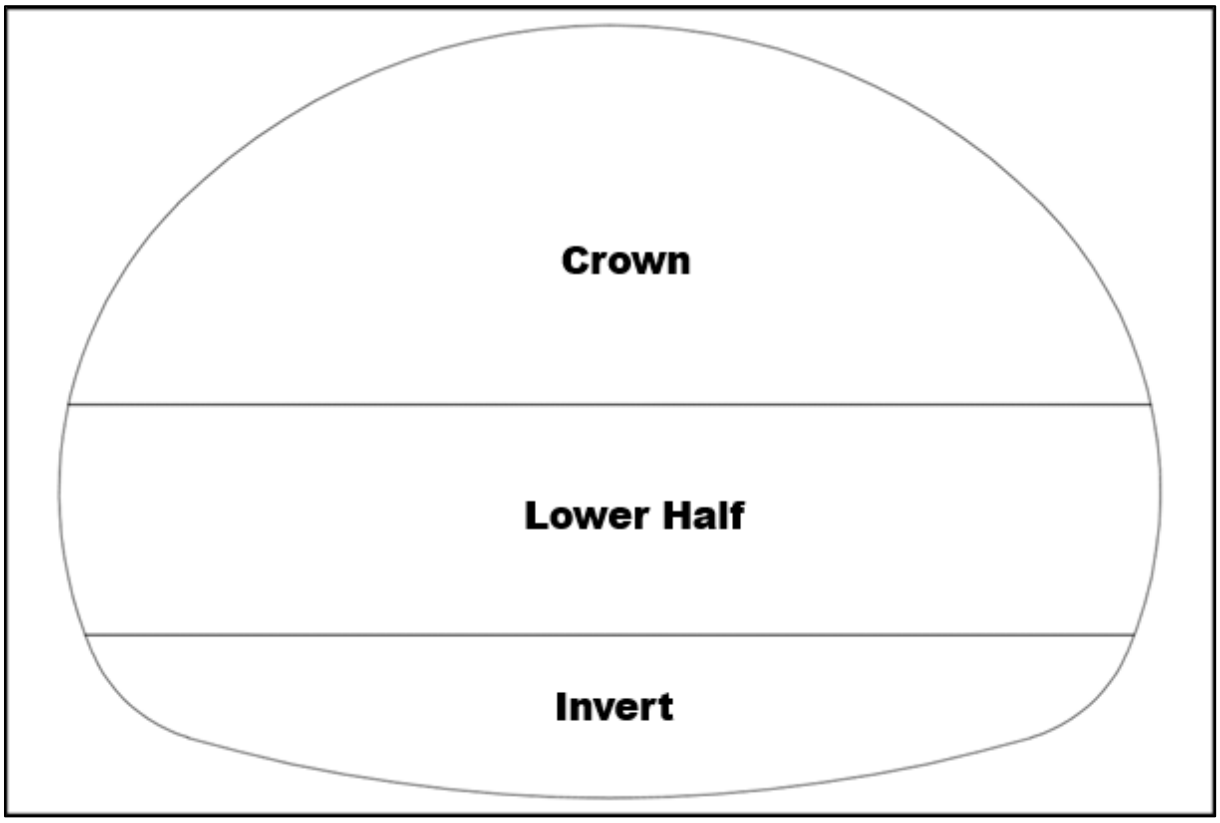

Figure XI.45 Base-arched tunnel excavation zones

The parameters and techniques used in the design of the blasting models are outlined below:

- A drill-hole diameter of 42 mm (within the range of 42–45 mm) is assumed.
- Emulsion explosive cartridges measuring 38 x 500 mm and weighing 0.5 kg are considered as the explosive material.
- All distances used in the designs are given in meters.

Quantities of Explosive Materials that may be needed during the Works

The quantities of explosives and accessories potentially required during the blasting excavation works for the Antalya – Alanya Motorway Project have been estimated.

The excavation phase is planned to last approximately 3 years, involving blasting for cuttings, foundations, and tunnels. The estimated excavation volume for cuttings and foundations is 17,500 m³, while the total excavation volume for tunnels is expected to be 14,000 m³. It is assumed that blasting will occur 26 days per month, 312 days per year, totaling 936 blasting days throughout the Project duration.

Based on the proposed blasting designs, the estimated quantities of explosives and accessories needed for cuttings and foundation excavations are provided in Table XI.27, while those for tunnel excavations are given in Table XI.28.

Table XI.27 Estimated quantities of explosive materials and accessories to be required for cutting and foundation excavations

Explosives and Accessories	Daily Requirement	Monthly Requirement	Annual Requirement	Total Requirement (Project Duration)
ANFO / Booster-sensitive emulsion explosive	100,000 kg	2,600,000 kg	31,200,000 kg	93,600,000 kg
Cap-sensitive emulsion explosive (dynamite)	9,500 kg	247,000 kg	2,964,000 kg	8,892,000 kg
Electronic detonator	5,000 units	130,000 units	1,560,000 units	4,680,000 units
Electric detonator	200 units	5,200 units	62,400 units	187,200 units
Non-electric detonator	19,000 units	494,000 units	5,928,000 units	17,784,000 units
Detonating cord	70,000 meters	1,820,000 meters	21,840,000 meters	65,520,000 meters

Table XI.28 Estimated quantities of explosive materials and accessories required for tunnel excavations

Explosives and Accessories	Daily Requirement	Monthly Requirement	Annual Requirement	Total Requirement (Project Duration)
Cap-sensitive emulsion explosive (dynamite)	4,500 kg	117,000 kg	1,404,000 kg	4,212,000 kg
Electronic detonator	1,500 units	39,000 units	468,000 units	1,404,000 units
Electric detonator	500 units	13,000 units	156,000 units	468,000 units
Non-electric detonator	3,000 units	78,000 units	936,000 units	2,808,000 units
Detonating cord	1,000 meters	26,000 meters	312,000 meters	936,000 meters

Evaluation of Air Shock Stone Skidding Distances That May Occur During Blast Excavations

The distances at which a 140 dB airblast effect would occur and the areas affected by flyrock have been calculated based on the amount of explosive material used per delay. General information about the site is provided in Table XI.29. The minimum distance that can be maintained from the nearest risk point based on the amount of explosive used per delay has been calculated and is presented in Table XI.30.

Table XI.29 General information about the site

General Information		Land Constants		Air Shock Constants	
Threshold Damage Limit PPV (mm/s)	Air Shock Effect Limit (db)	K	β	K	β
15	140	1,884.9	1.605	24.8	1.1

Table XI.30 Calculation according to the amount of explosive material to be used per delay for 15 mm/s using Equation 3

Calculation according to the amount of explosives to be used per delay			
Blast Details		**Results**	
Maximum Explosive Charge per Delay (kg)	Allowable Distance to the Nearest Structure from the Risk Point (m)	Distance that can be achieved to avoid exceeding 140 dB air shock	Flyrock Risk Distance (m)
10.82[4]	66.8	21.8	65.3

Based on the calculations provided in Table XI.31, the maximum flyrock distance and the air shock distance corresponding to a sound pressure level of 140 dB have been determined for a charge weight of 10.82 kg per delay, with a threshold of 15 mm/s for durable structures located near settlements. These distances are illustrated on a representative model shown in Figure XI.46.

Table XI.31 Calculations based on the distance to the risk point for a vibration of 15 mm/s using Equation 3

Distance to Risk Point (m)	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 15 mm/s Threshold Damage Limit	Distance (m) Subject to 140 dB Air Overpressure Based on the Explosive Charge Used	Flyrock Impact Zone Based on the Explosive Charge Used (m)
50	6.06	18	45.00
100	24.22	29	55.00
150	54.50	37	125.00
200	96.88	45	3,339.00
250	151.38	53	3,339.00
300	217.98	59	3,339.00
350	296.70	66	3,339.00
400	387.52	72	3,339.00

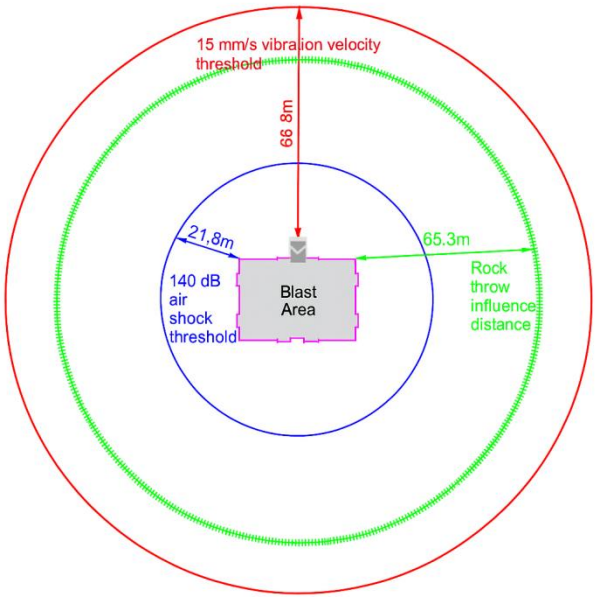

Figure XI.46 Area of effect when using 10.82 kg of explosives per delay

Blasting Design Considerations for Vibration during Construction

For all operations, the blasting design specifies a charge weight of 10.82 kg per delay. For quarry operations, this charge is intended to control vibrations at 15 mm/s for durable structures and 8 mm/s for vibration-sensitive structures, with safe distances of 66.8 meters and 98.8 meters, respectively. For tunnels, cuts, and foundation excavations, the same explosive charge is used to limit vibrations to 10 mm/s for durable structures and 5 mm/s for vibration-sensitive structures, with corresponding safe distances of 86 meters and 132.5 meters.

Table XI.32 illustrates how the maximum allowable explosive charge per delay varies with distance to ensure vibration limits are not exceeded. For a charge of 10.82 kg, safe distances range from about 66.8 meters for the 15 mm/s vibration limit typical of durable structures, up to 132.5 meters for the strict 5 mm/s limit used for highly sensitive structures. At closer distances, the allowable charge decreases sharply. For example, at 5 meters, only 0.06 kg is permitted under the 15 mm/s limit, and as little as 0.02 kg for the 5 mm/s threshold.

Table XI.32 Calculations based on the distance to the risk point for different vibrations using Equation 3

Distance to Risk Point (m)	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 15 mm/s Threshold Damage Limit	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 10 mm/s Threshold Damage Limit	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 8 mm/s Threshold Damage Limit	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 5 mm/s Threshold Damage Limit
5	0.06	0.04	0.03	0.02
10	0.24	0.15	0.11	0.06

40	3.88	2.34	1.77	0.99
50	6.06	3.65	2.77	1.54

Distance to Risk Point (m)	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 15 mm/s Threshold Damage Limit	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 10 mm/s Threshold Damage Limit	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 8 mm/s Threshold Damage Limit	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 5 mm/s Threshold Damage Limit
60	8.72	5.26	3.98	2.22
66.8	10.81	6.52	4.94	2.75
70	11.87	7.16	5.42	3.02
80	15.50	9.35	7.08	3.94
86	17.91	10.81	8.18	4.56
90	19.62	11.84	8.96	4.99
98.9	23.69	14.29	10.82	6.03
100	24.22	14.61	11.07	6.16
110	29.31	17.68	13.39	7.45
120	34.88	21.04	15.94	8.87
130	40.93	24.70	18.70	10.41
132.5	42.52	25.66	19.43	10.82

Based on a charge weight of 10.82 kg per delay, the safe distances and vibration limits for quarry blasting are illustrated in Figure XI.47, while those for tunnel, cut, and foundation blasting are shown in Figure XI.48.

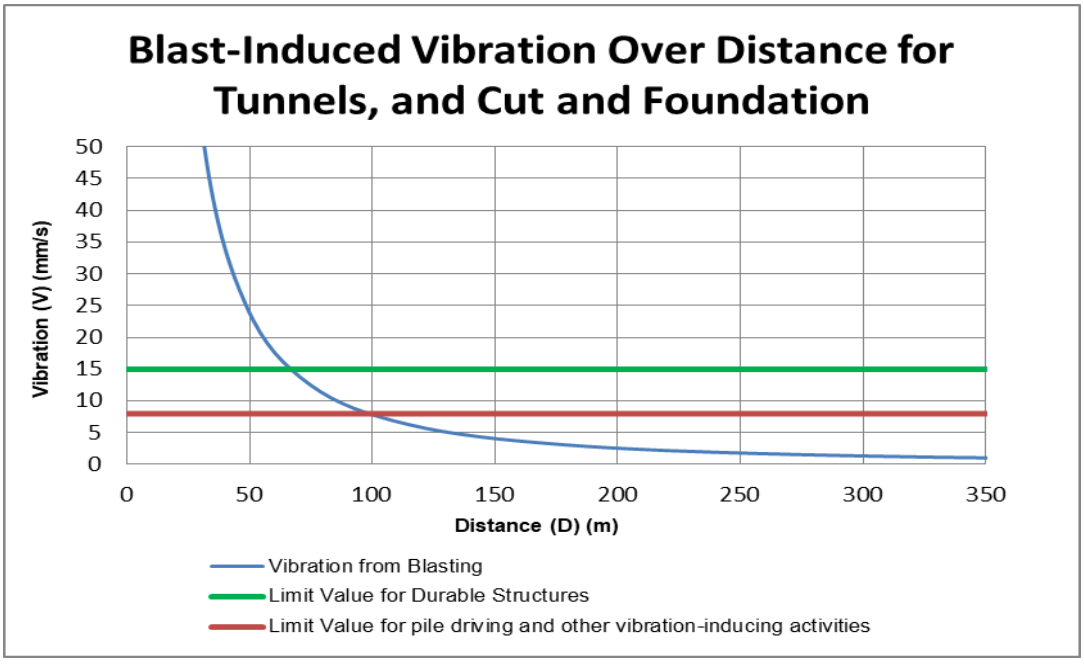

Figure XI.47 Blast-Induced Vibration of 15 mm/s and 8 mm/s over Distance

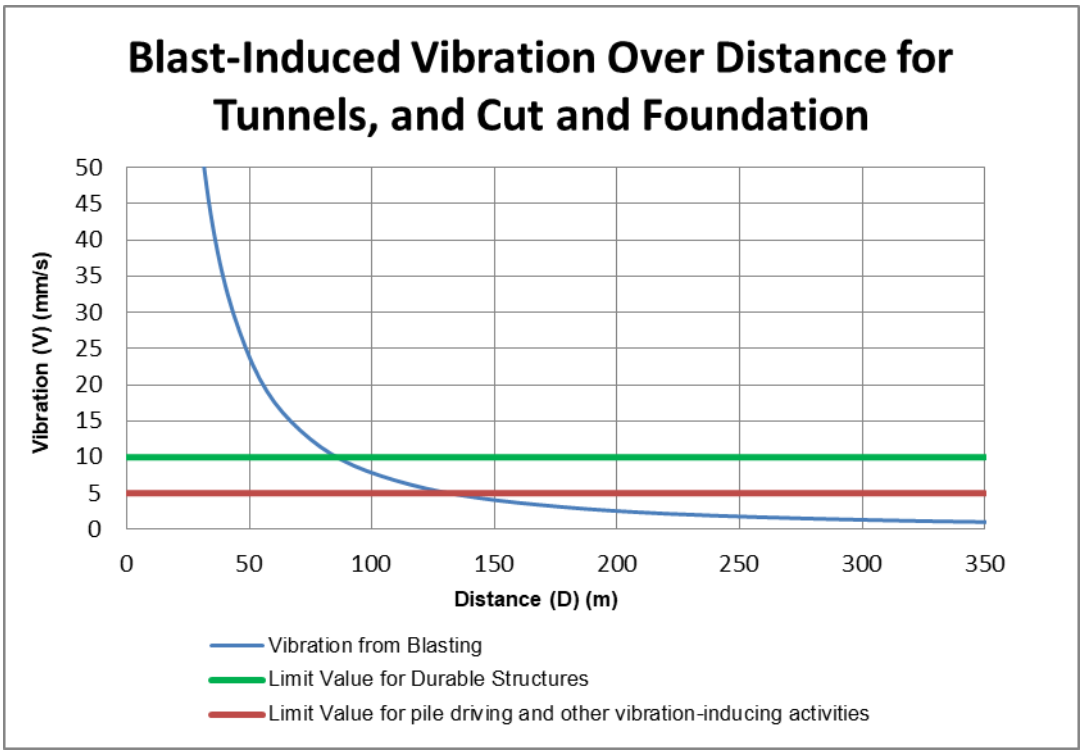

Figure XI.48 Area of effect of Blast-Induced Vibration over Distance for Tunnels, and Cut and Foundation

To assess the potential vibration impacts caused by blasting activities, sensitivity analyses were conducted individually for the settlements that may be affected by the planned tunnel and cut blasting operations. The results of these analyses are presented in Table XI.33 and the geographical distribution of the sensitivity analyses for the settlements that may be affected by the planned tunnel and cut blasting operations is presented in Figure XI.49 through Figure XI.53.

To support these findings, blast vibration assessments were carried out (using the equation 3 and the values of Kahriman et al. (2019) with the constants K= 1884.9 and β =1.605) to identify areas that may be subject to potential impacts based on their proximity to vibration-sensitive structures. For tunnels (Table XI.33), and cuts and foundations (Table XI.35), the vibration limits are set at 10 mm/s for durable structures and 5 mm/s for vibration-sensitive structures such as mosques, cultural heritage sites, and schools. In contrast, for quarries and borrow pits (Table XI.34), the allowable limits increase to 15 mm/s for durable structures and 8 mm/s for vibration-sensitive structures. These assessments help determine which environments could pose risks to sensitive sites and guide the implementation of appropriate safety standards.

**See Chapter 13 for the details of the locations of Cultural Heritage sites*
*** Site-specific vibration measures for the protection of cultural heritage sites have been detailed in the Table XI.36 to address these potential impacts.*

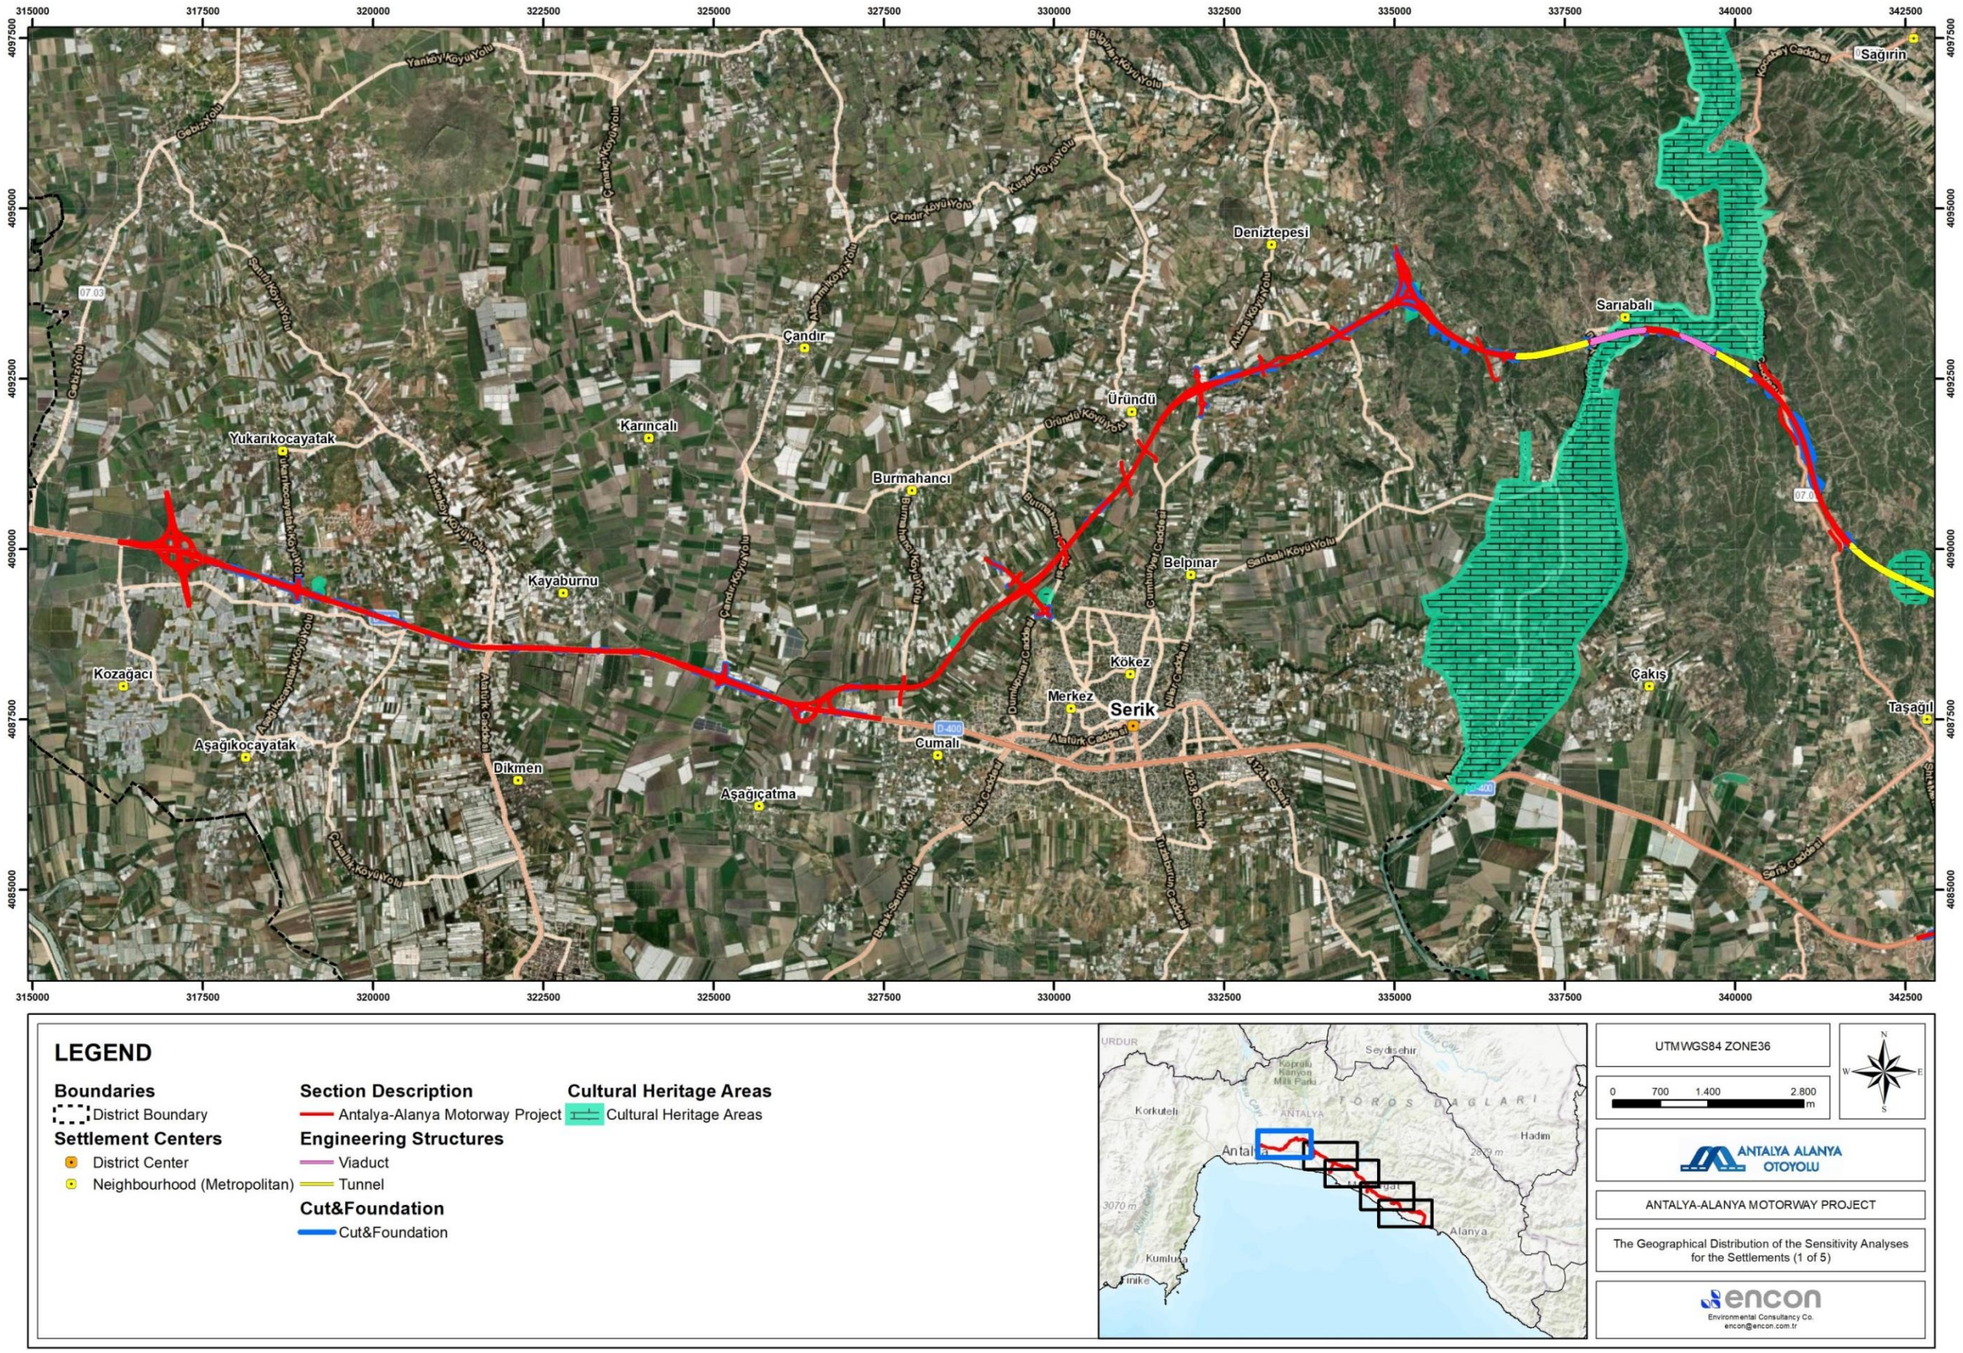

Figure XI.49 The geographical distribution of the sensitivity analyses for the settlements-1

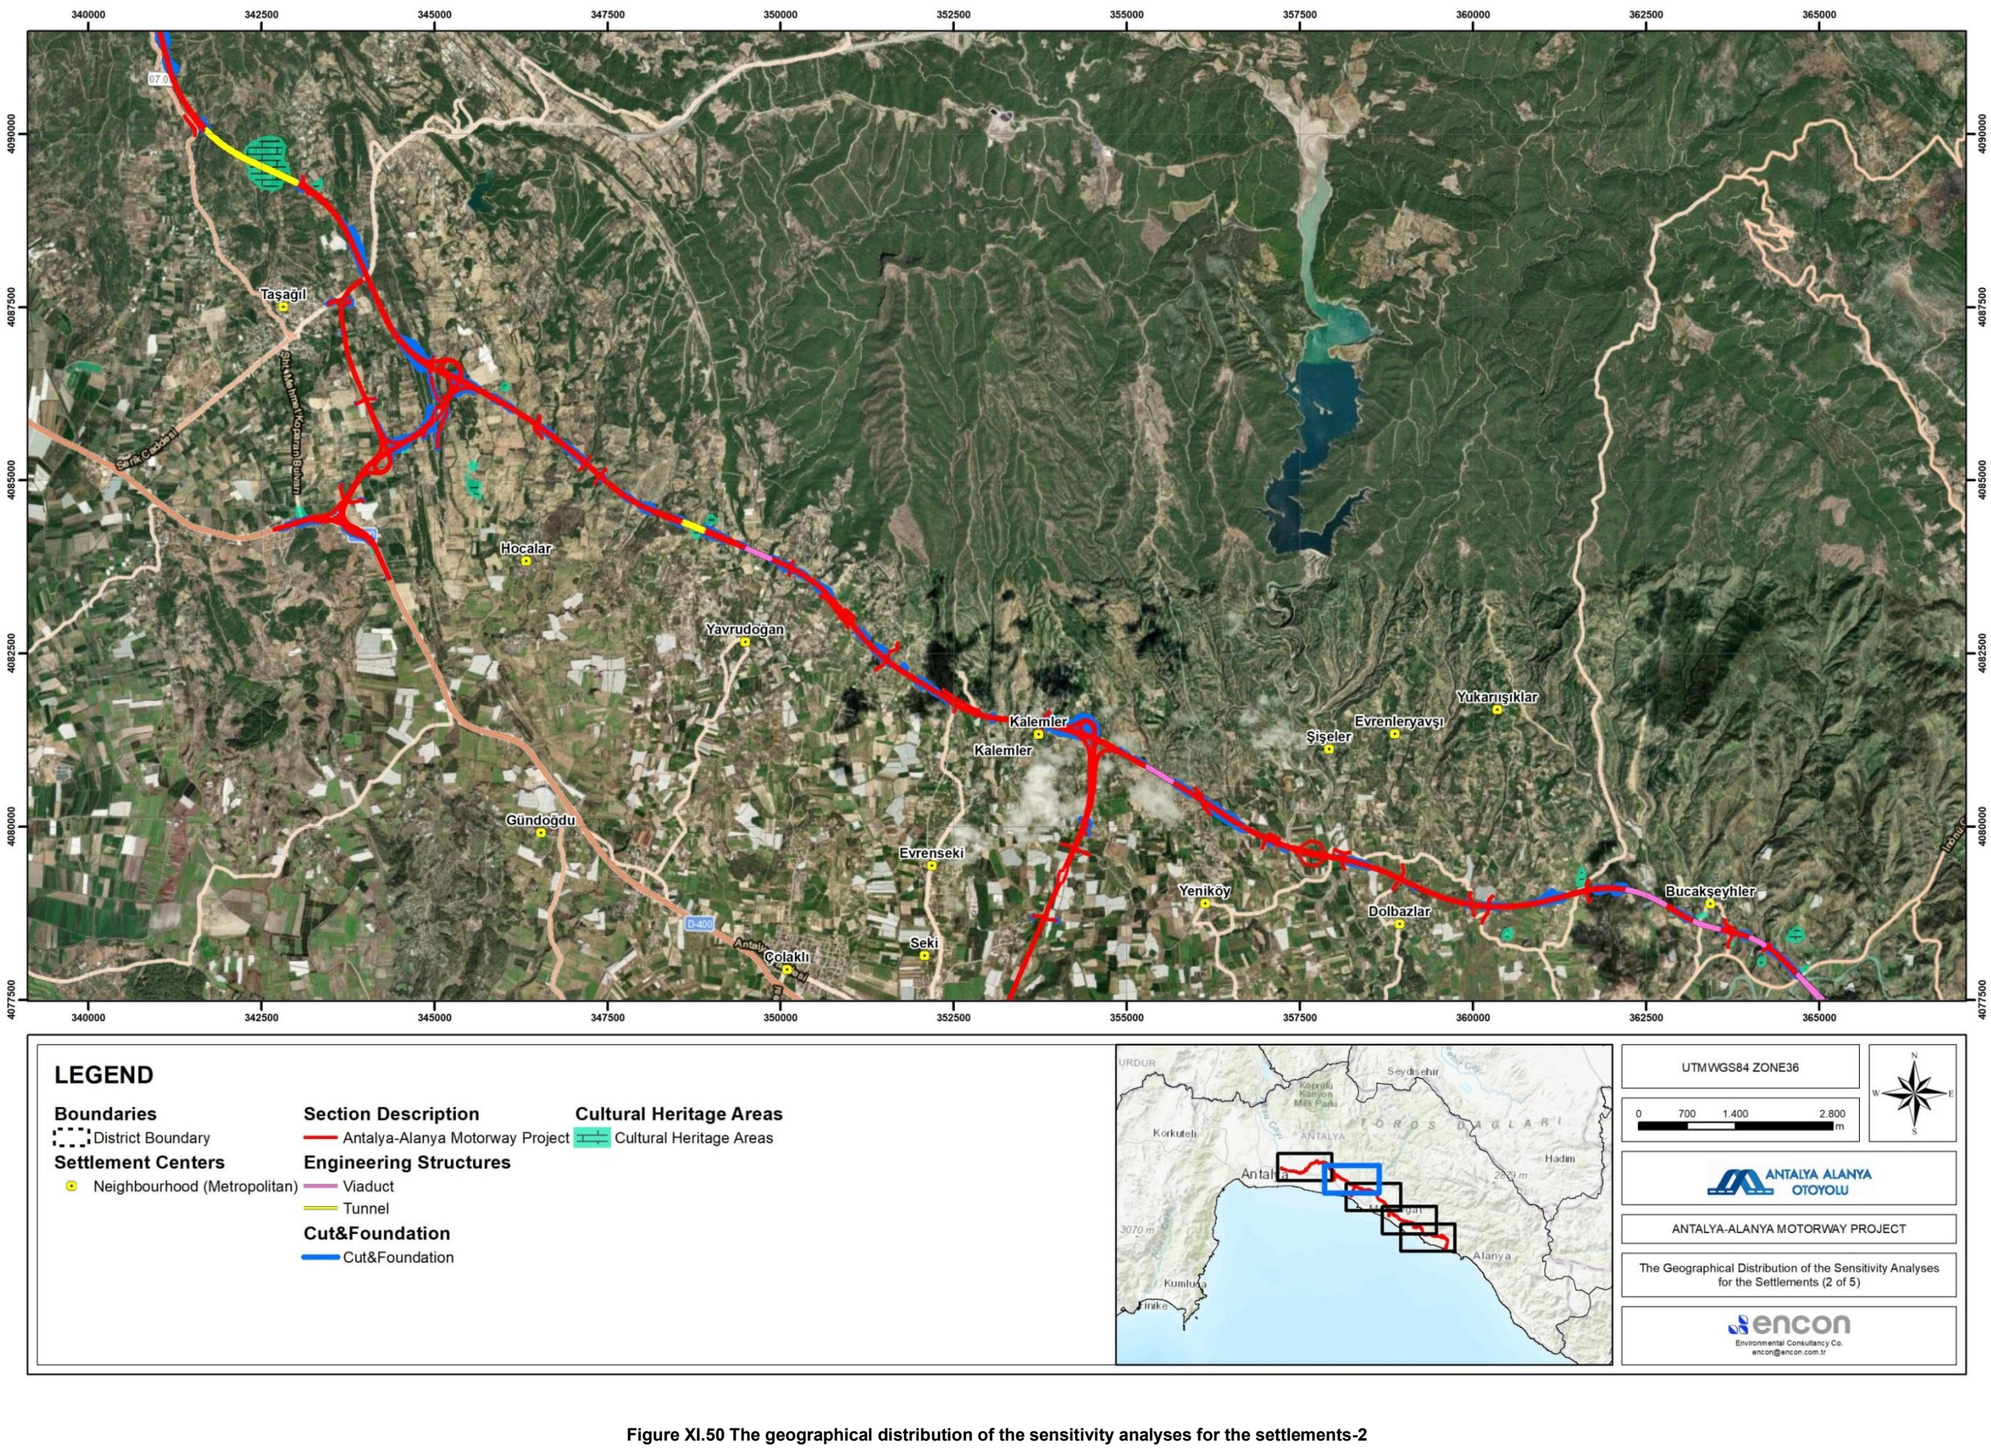

Figure XI.50 The geographical distribution of the sensitivity analyses for the settlements-2

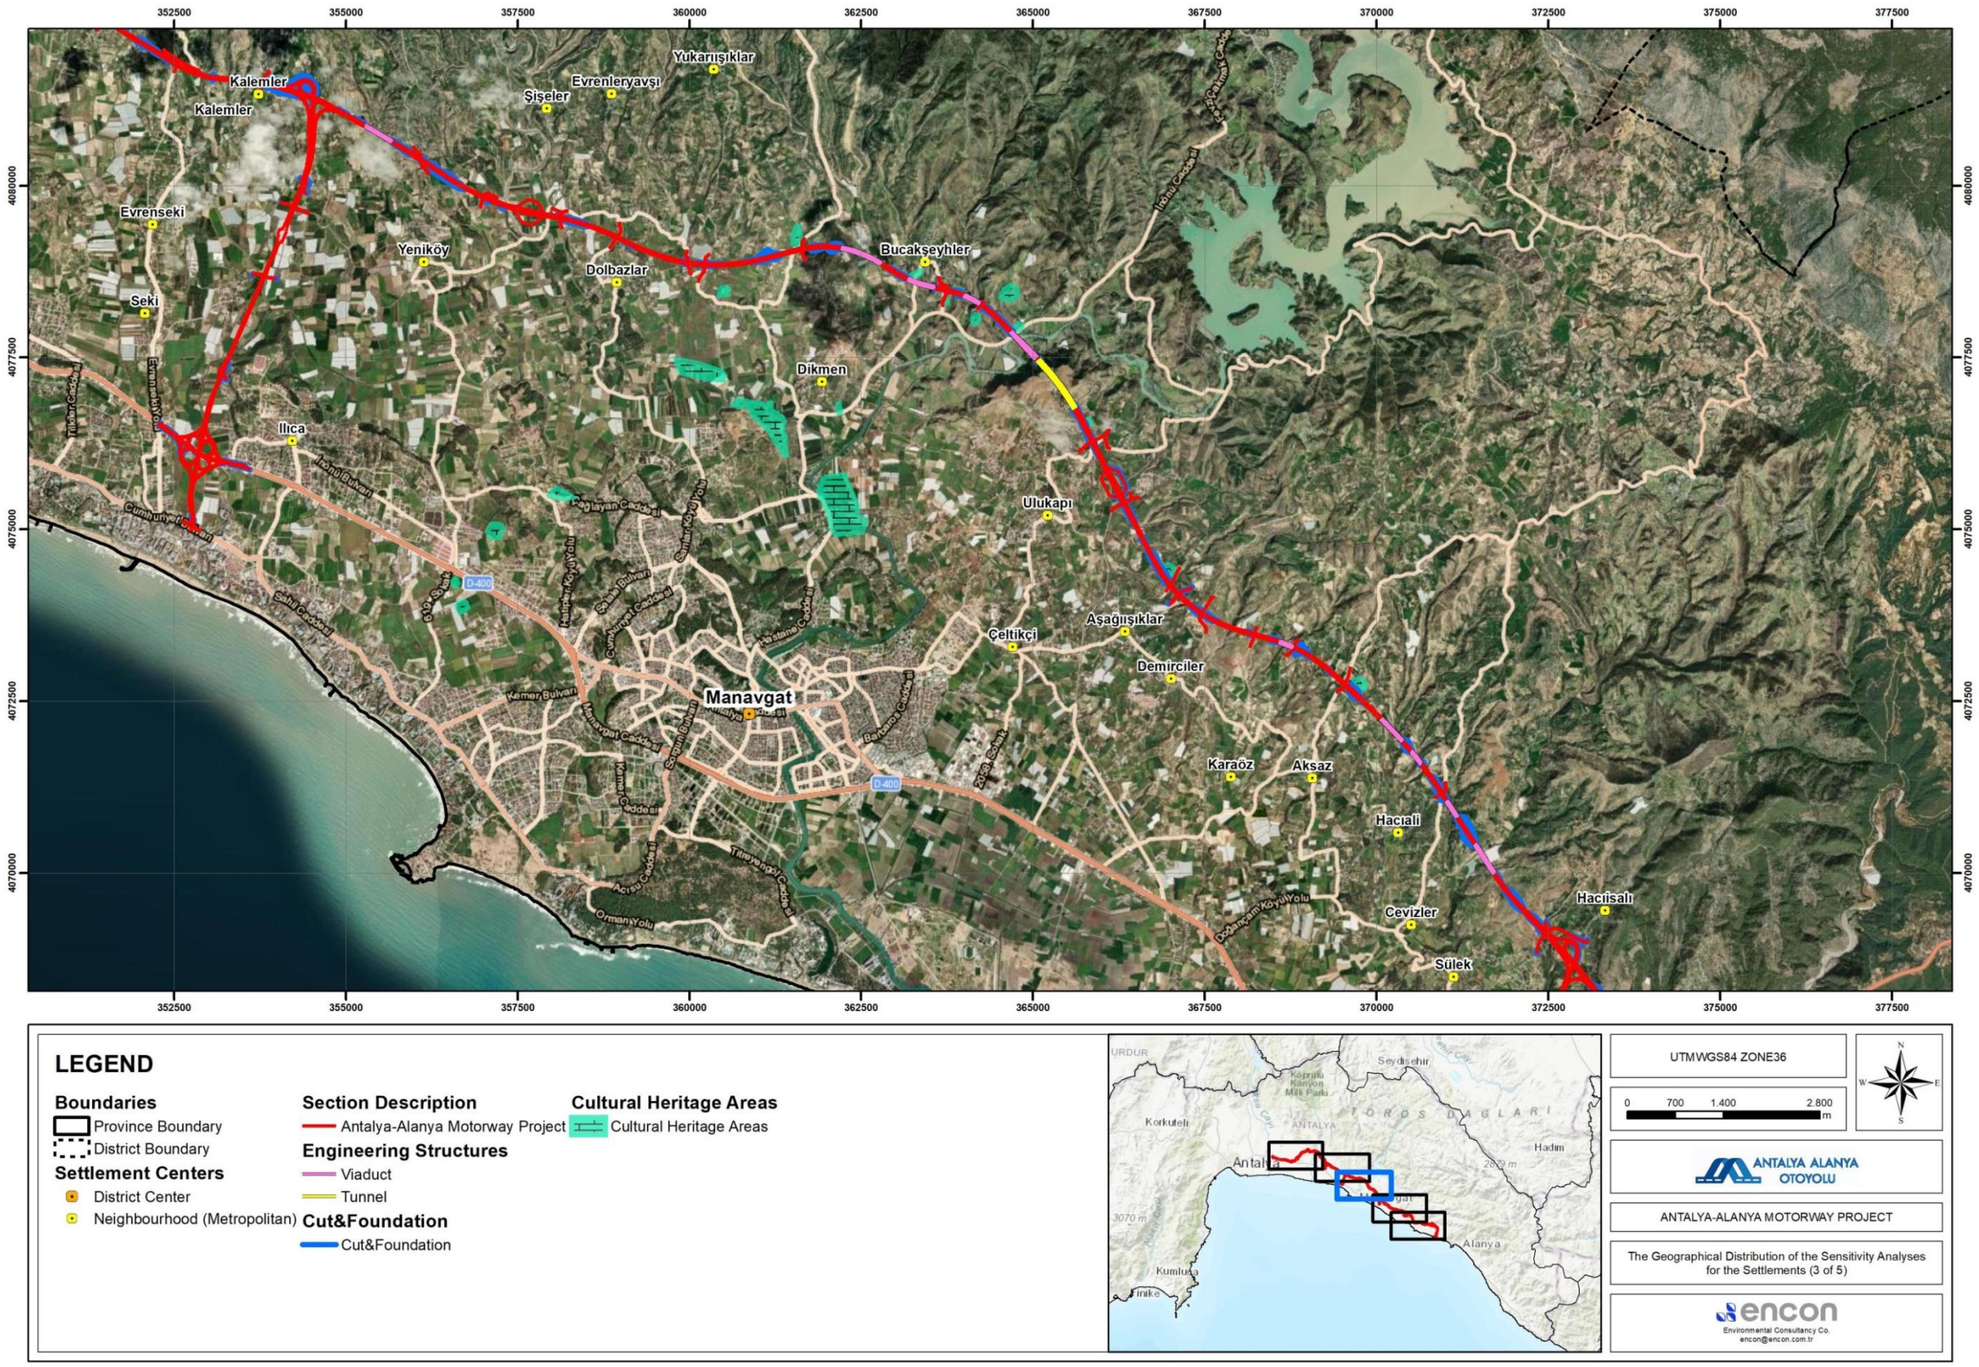

Figure XI.51 The geographical distribution of the sensitivity analyses for the settlements-3

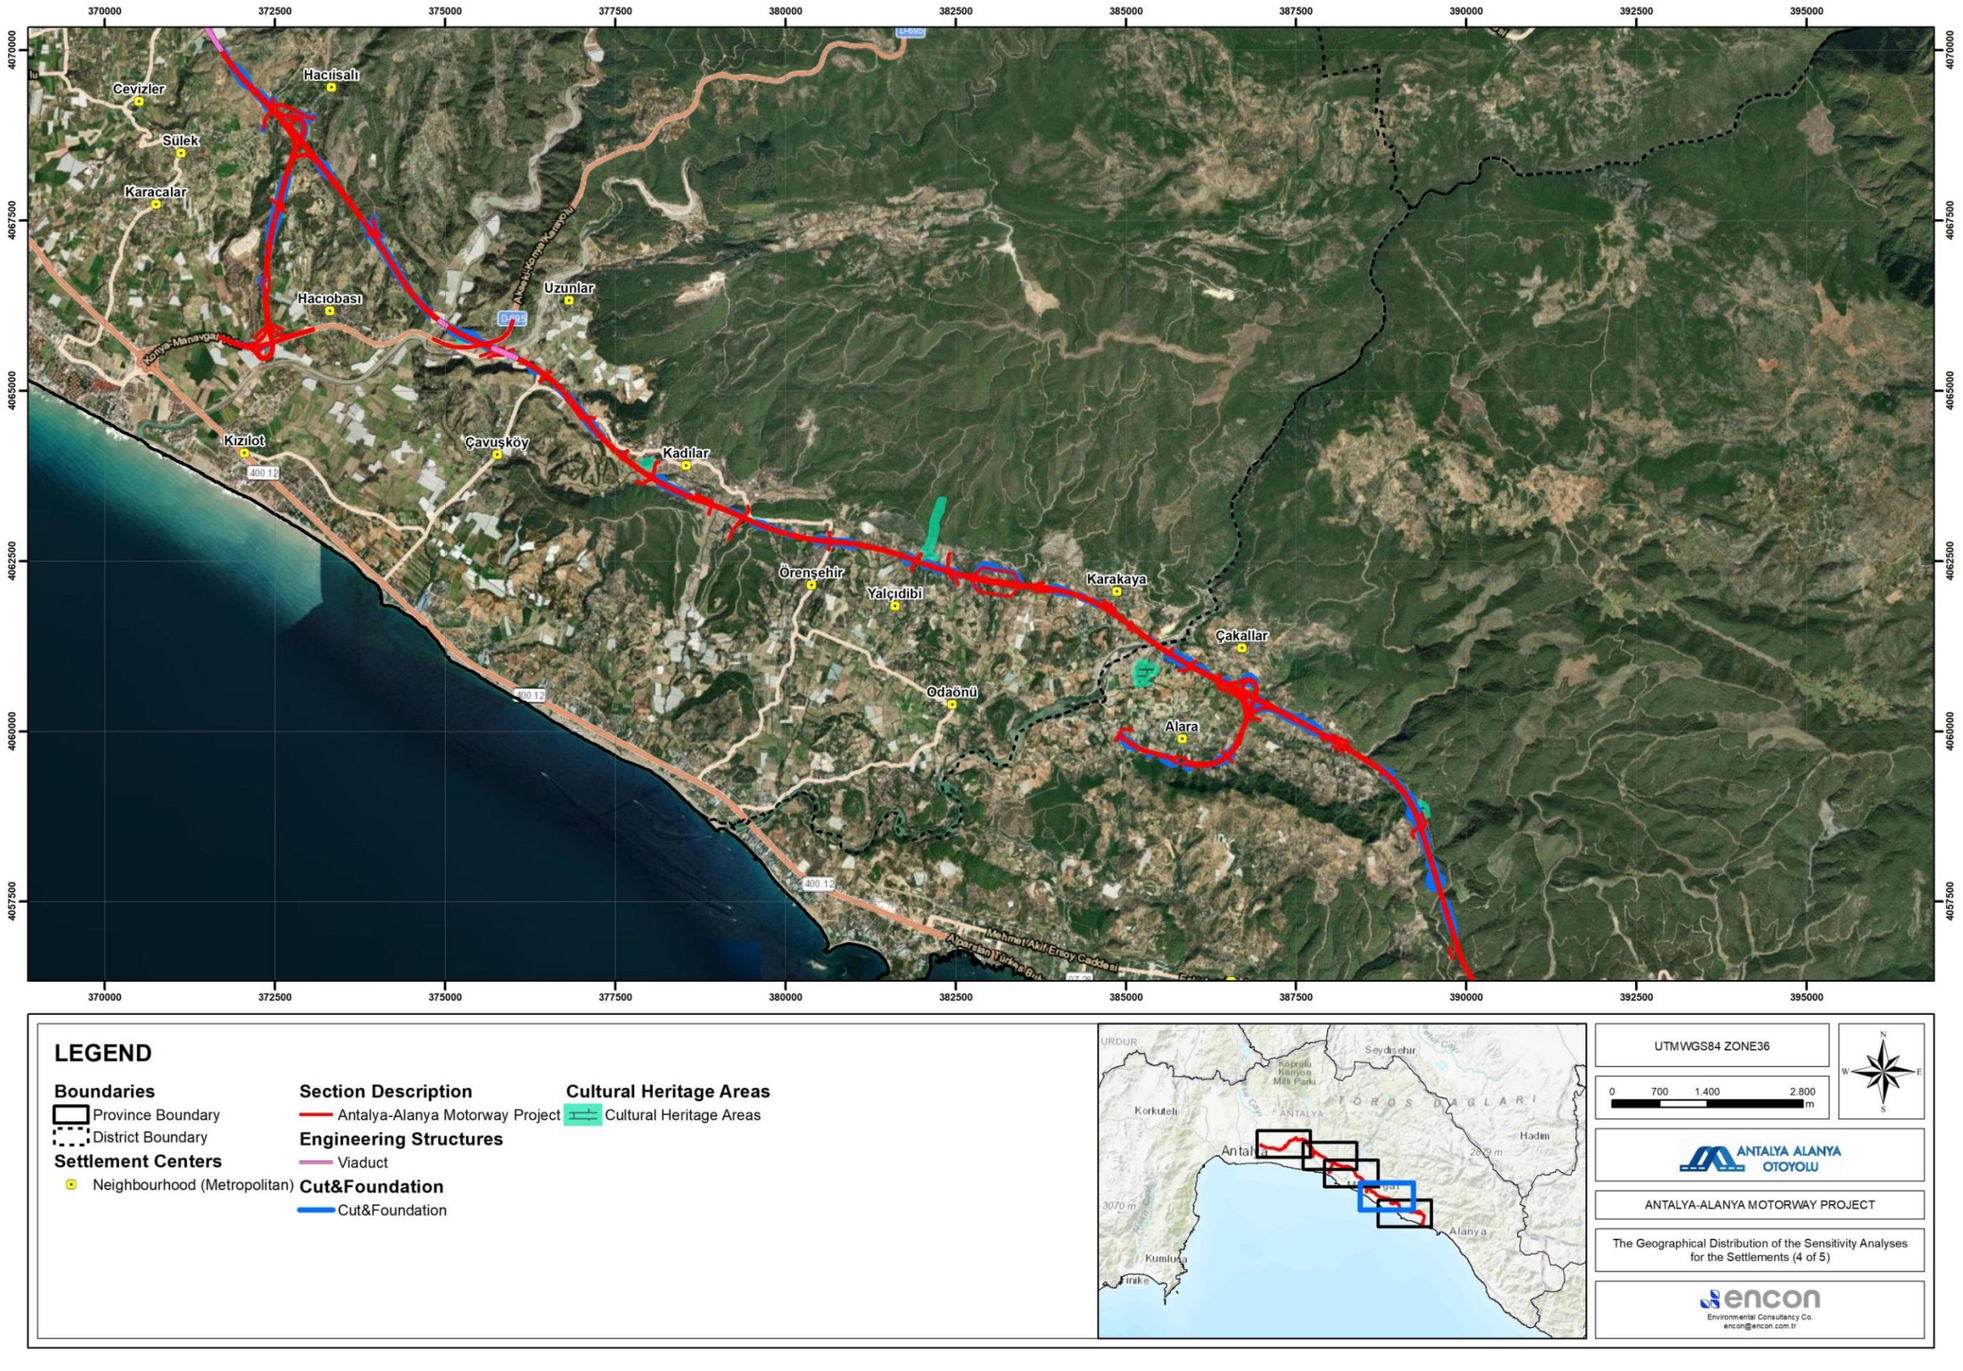

Figure XI.52 The geographical distribution of the sensitivity analyses for the settlements-4

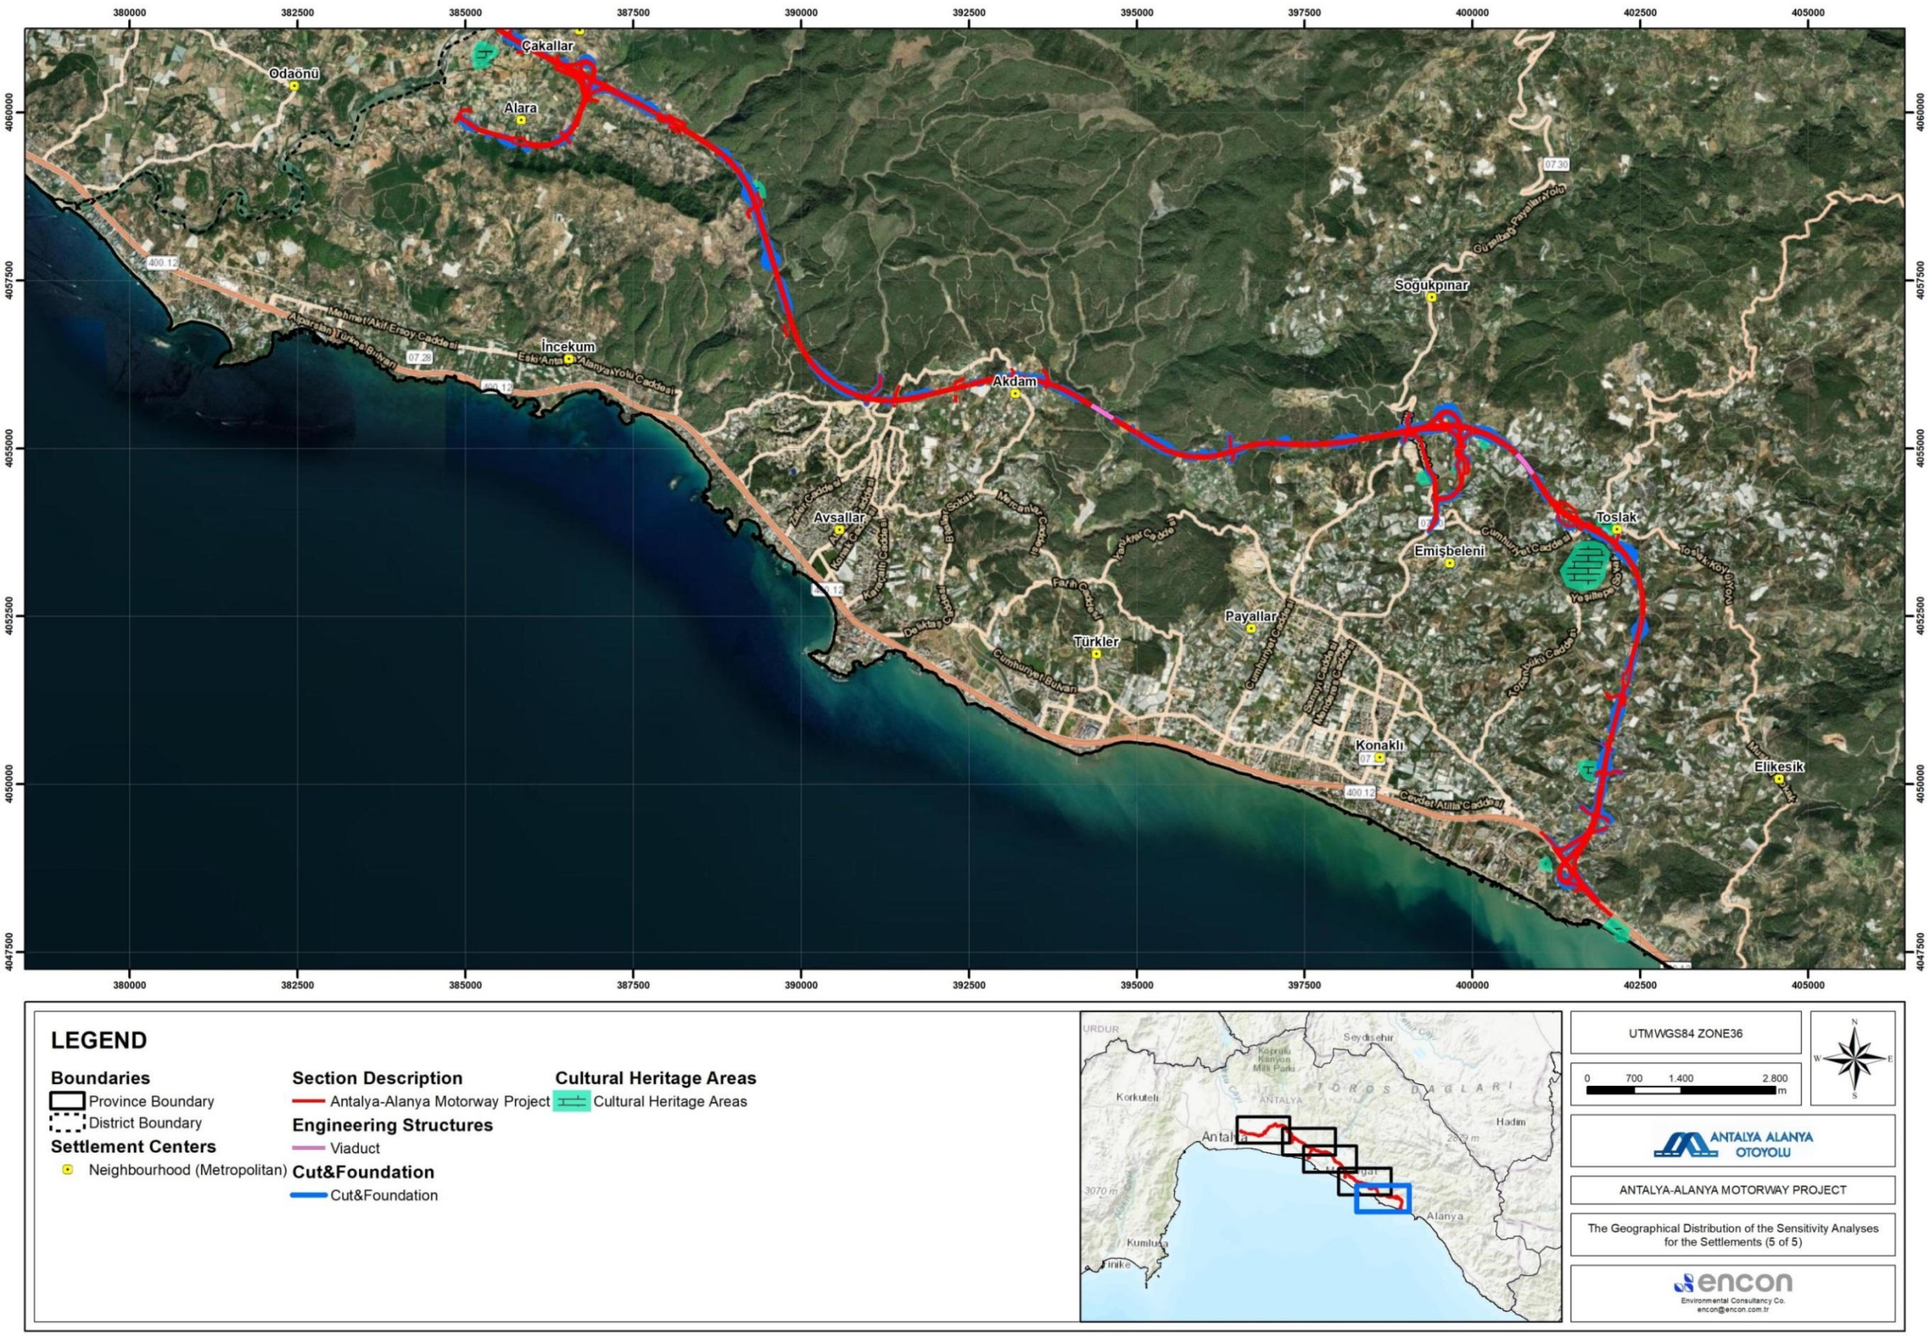

Figure XI.53 The geographical distribution of the sensitivity analyses for the settlements-5

To address the environmental impacts of blasting at the specified locations concerning ground vibration, site-specific actions detailed in have been implemented or are planned for the identified cultural heritage sites (HRM 5, HRM 8, HRM 9, HRM 16, HRM 20, HRM 38, HRM 41, HRM 45, HRM 50, HRM 51, HRM 52, HRM 53, HRM 57, and HRM 58), particularly where vibration-sensitive structures are located within 132.5 meters and the potential for threshold exceedance is elevated (Table XI.36).

For HRM 5, salvage excavation is underway, with construction paused until the salvage excavation is finished.

For HRM 6, no blasting will be carried out before the decision of the conservation board; discussions with the institution are ongoing. After the decision a control survey will be done on the area. The measures determined by the institution will be implemented based on the results of the survey.

HRM 9 has not been registered by the Board (Permitting date and No.: 26.12.24/18914) and a construction permit has been granted for working on this area. In accordance with Article 4 of Law No. 2863, if any archaeological remains are encountered during construction, all activities must be halted immediately and the Museum Directorate must be notified.

For HRM 16, at 60 meters, the maximum charge per delay (kg) will be reduced as shown in Table XI.36.

For HRM 20 is a 1st degree archaeological site (Aqueduct that supplied water to the ancient city of Side), and to protect it, a 100-meter buffer zone will be established between the blasting location and the archaeological site to provide protection, and no activity will be carried out within this zone. The opinion of the Antalya Board will be sought before any activity begins.

For HRM 38, which is already located on a hilltop, the blasting activities are confined to the lower slopes below, and a recent design revision incorporating a shoring wall has clearly defined the work zone. Within this boundary, the use of minimal explosives or mechanical breaking methods will help reduce potential vibration impacts on the site above. Based on the calculations presented in Table XI.23, the maximum distance at which the PPV reaches 2 mm/s is 8.6 meters. Therefore, the mechanical breaker's vibrations are not expected to affect the cultural heritage sites except for HRM 6 which is still being processed by the board.

For HRM 50, HRM 51, and HRM 52, at distances of 70, 100, and 106 meters respectively, will implement tailored reductions in maximum charge per delay based on proximity and sensitivity.

For HRM 8, HRM 41, HRM 45, HRM 53, HRM 57 and HRM 58, a minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed. Based on the calculations presented in Table XI.23, the maximum distance at which the PPV reaches 2 mm/s is 8.6 meters. Therefore, the mechanical breaker's vibrations are not expected to affect these cultural heritage sites except for HRM 6 which is still being processed by the board. Preliminary assessments indicate that all six sites will require controlled blasting, but only where distances exceed the 56.96-meter threshold. Excavation activities conducted beneath this threshold will be carefully managed to mitigate residual risks in close proximity to archaeological features.

These measures ensure compliance with established ground vibration thresholds, 15 mm/s at 66.8 m and 8 mm/s at 98.4 m for quarries, and 10 mm/s at 86 m and 5 mm/s at 132.5 m for tunnels and cut-and-formation works, while protecting cultural heritage and nearby settlements. A minimum charge of 2 kg for 3 m hole (as common practice) (ANFO powder + dynamite) produces a peak particle velocity of 5 mm/s at a distance of 56.96 meters, establishing a conservative baseline for safe blasting near sensitive archaeological features. No blasting will be conducted within 56.96 meters; mechanical breaker's vibrations are not expected to affect the cultural heritage sites except for HRM 6 which is still being processed by the board.

Table XI.36 Site-Specific Vibration Measures for Cultural Heritage

Site	Explanation	Distance (m)	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 5 mm/s Threshold Damage Limit	Mitigations	Residual Impact	Assurance Measures
HRM 5	This area is currently undergoing salvage excavation. Construction activities will only proceed once the archaeological excavation has been fully completed and the necessary approvals have been obtained from the Board, the Municipality, and the Republic of Türkiye Ministry of Environment, Urbanization and Climate Change. Upon permit approval, minimal explosive charges will be used to prevent damage to the site.	5	0.0154	Wait until the excavation is finished	Change of location of the site	Archaeological surveys coordinated with the Museum Directorate.
HRM 6	Remains of an architectural structure, possibly from the Roman Period, likely representing a frontier garrison settlement. A dense accumulation of rubble stone and visible wall rows, which may belong to the structure, are present on the surface. Additionally, numerous roof tile fragments and a small number of sherds from daily use vessels have been observed.	5	0.0154	No blasting will be carried out before the decision of the conservation board. After the decision a drilling operation will be done on the area. The measures determined by the Board will be implemented based on the results.	-	-
HRM 8	This area is a natural protected zone. Therefore, throughout the entire process, we will reduce the maximum charge per delay (kg) and conduct survey and monitoring activities through an external contractor.	53	1.7306	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be placed at 53 m, with weekly ecological surveys and compliance reporting to the Ministry of Environment.
HRM 9	This area was not Registered by the Board and construction permit has been obtained. But in case of Chance Find during the construction, Article 4 of Law No. 2863, the work is to be halted, and the Museum Directorate must be notified.	-	-	Visual inspections for chance find.	Negligible risk unless chance finds occur.	An on-site archaeological observer will monitor works, with immediate halting and notification to the Museum Directorate in case of chance finds (Law No. 2863).
HRM 16	Lowering the maximum Charge per Delay (kg).	60	2.2179	Use a charge of 2.2 kg with electronic detonators.	PPV: 4.968 mm/s. Low risk or negligible, but nearing threshold. Monitoring recommended during blasting.	Seismographs will be positioned at 60 m, and a pre-blast structural stability survey will be conducted.
HRM 20	This area is not located on the project route, but is located within the Dikmen Quarry. The HRM-20 registered archaeological site is an aqueduct that supplied water to the ancient city of Side. Because the area has been designated a first-degree archaeological site, the opinion of the Antalya Board will be sought before any activity begins. Additionally, a 100-meter buffer zone will be established between the blasting area and the archaeological site to provide protection, and no activity will be carried out within this zone.	100	6.1608	A charge of 6.15 kg using electronic detonators will be employed. A 100 m buffer zone from the ancient waterway must be maintained. The site is currently on standby. If the appointed specialist contractor determines that blasting is not a viable option, mechanical breaking may be used as an alternative.	PPV: 4.968 mm/s. Low risk or negligible, but nearing threshold. Monitoring recommended during blasting.	Seismographs will be positioned at 100 m, and a pre-blast structural stability survey will be conducted.
HRM 38	The archaeological site lies at the summit of the hill, whereas the designated blasting area is located along the foothill. Given the topographical separation and distance, vibrations are expected to be attenuated. Furthermore, the recent design change led to the determination of the work area by the shoring (IKSA) wall, which established a clear boundary. Within this defined area, preventive measures can be implemented using a small amount of explosives or through mechanical breaking methods to minimize any potential impact as explained in the above paragraphs.	15	0.1386	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs. A shoring (IKSA) wall will be installed to minimize vibration, and stemming applied to limit air overpressure near the site. Based on the external contractor the charge can be modified based on the attenuation.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be placed at 15 m and behind the IKSA wall, with structural surveys of the hill summit before and after blasting.
HRM 41	Lowering the maximum Charge per Delay (kg).	20	0.2464	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be installed at 20 m to monitor vibration attenuation over distance.
HRM 45	Lowering the maximum Charge per Delay (kg.	30	0.5545	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be installed at 30 m to verify compliance with PPV limits.
HRM 50	Lowering the maximum Charge per Delay (kg).	70	3.0188	Use a charge of 3 kg with electronic detonators.	PPV: 4.975 mm/s. Low or negligible risk, but nearing threshold. Monitoring recommended during blasting.	Seismographs at 70 m to monitor vibration attenuation over distance. Pre-blast survey.

Site	Explanation	Distance (m)	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 5 mm/s Threshold Damage Limit	Mitigations	Residual Impact	Assurance Measures
HRM 51	Lowering the maximum Charge per Delay (kg).	100	6.1608	Use a charge of 6.15 kg with electronic detonators.	PPV: 4.993 mm/s. Low or negligible risk, but nearing threshold. Monitoring recommended during blasting.	Seismographs at 100 m to monitor vibration attenuation over distance.
HRM 52	Lowering the maximum Charge per Delay (kg).	106	6.9222	Use a charge of 6.92 kg with electronic detonators.	PPV: 4.999 mm/s. Low risk or negligible, but nearing threshold. Monitoring recommended during blasting.	Seismographs will be installed at 106 m to monitor vibration attenuation over distance.
HRM 53	Lowering the maximum Charge per Delay (kg).	29	0.5181	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs .	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs at 29 m to monitor vibration attenuation over distance.
HRM 57	With the design change, the route was moved outside the archaeological site, reducing potential impacts. A preliminary survey will be done to assess the situation, and measures like reducing explosives use will be applied.	10	0.0616	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible..	Seismographs will be placed at 10 m, with archaeological monitoring to ensure protection of heritage assets.
HRM 58	With the design change, the route was moved outside the archaeological site, reducing potential impacts. A preliminary survey will be done to assess the situation, and measures like reducing explosives use will be applied.	10	0.0616	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be placed at 10 m, with archaeological monitoring to ensure protection of heritage assets.

At the Kuruçay (TOY4b) Quarry and at Km 52+500, Km 85+000, Km 95+500, Km 112+000, Km 136+000, and Km 140+000, the blasting pattern will be selected based on the presence of vulnerable sensitive.

In addition to vulnerable structures, some durable structures located nearby may also experience potential impacts due to flyrock and ground vibrations. The areas potentially affected include the neigborhoods of Sarıabalı, Taşağıl, Yavrudoğan, Kalemler, Yukarıışıklar, Dikmen, Karaöz, Aksaz, Hacıali, Hacıaisalı, Yalçıdibi, Çakallar, Akdam, Soğukpınar, Toslak, and Konaklı.

To reduce potential environmental impacts, it is recommended to use low-charge and delayed blasting techniques in areas close to setllements. Protective nets or coverings should be used to secure blasting zones and minimize the risk of rock throw. In additionmonitoring systems for vibration should be installed in high-risk areas, and local communities should be informed prior to blasting activities with appropriate safety measures in place. Detailed information is given in Table XI.39.

Due to the highly variable and often unpredictable geological conditions found within a tunnel the start and end points only have been defined in the blasting plan. The specific details regarding the blasting approach, including the charge per delay and blast pattern, will be determined by a consultant as the work progresses. This tailored risk mitigation strategy is necessary because the content and composition of the rock cannot be fully known in advance. Also, the consultant will conduct a blast attenuation survey to precisely determine how vibrations decrease with distance and the attenuation, ensuring that the impact on nearby receptors is accurately measured and kept within safe limits.

In addition, to enhance the efficiency and safety of blasting and drilling operations, the Project engaged a specialized contractor. In cases where Potential Impact Zones are identified and cannot be mitigated through design modifications or excavation adjustments, the contractor will implement a tailored risk mitigation strategy. This includes modifying the blast pattern and adopting a specialized low-risk blasting approach, such as reducing the charge per delay, to minimize potential hazards while maintaining operational effectiveness. Additionally, the a specialized consultant will be responsible for conducting a blast attenuation survey to determine the distance at which vibration levels decrease to lower magnitudes.

XI.2.3.2. Operation Phase

Vibration perceived in a building structure close to a road with heavy traffic load is generally below 1 mm/s and found to rarely exceed 2 mm/s. This corresponds to normal levels of vibration generated during normal use of a building (for example, walking and closing doors). It is known that structural damage caused by vibration to buildings can occur above 10 mm/s levels which correspond to 10 times higher vibration levels expected from roads. (UK Highways Agency, 2011) So, the operation of a motorway is unlikely to cause significant vibration impacts on properties located in the vicinity.

Table XI.37 shows human response levels to continuous vibration from traffic. With vibration levels of 1-2 mm/s observed in heavy traffic roads, human response to vibration will remain at perceptible levels but will not reach level of annoying.

Table XI.37. Human Response to Continuous Vibration from Traffic

Vibration (PPV – mm/sec)	Human Response
10.16-15.24	Unpleasant
5.08	Annoying
2.54	Begins to annoy
2.03	Readily perceptible
0.15-0.48	Threshold of perception

Source: (Jones & Stokes, 2004)

XI.2.4. Mitigation Measures

XI.2.4.1. Land Preparation and Construction Phase

Blasting operations conducted as part of the Project will result in intermittent vibration impacts. The following measures will be taken to avoid and/or minimize relevant impacts on the local communities:

- Prior to the blasting operations, the sensitivity of nearby settlements/buildings against noise and vibration will be assessed. Buildings located within 100 meters of major vibration sources will be identified and assessed for vibration sensitivity prior to construction. Structural conditions of buildings located within 100 meters of the motorway alignment will be recorded before and after construction works to assess any possible vibration-induced damage.
- One day before the blasting activities, the Turkish gendarmerie should be notified, announcements from the mosque should be done and protective barriers should be implamanted.
- During the entire construction phase, regular surveys will be carried out throughout blasting and drilling activities by the contractor, capturing photographic records of all structures adjacent to blasting areas to detect and evaluate any damage that may arise post-blasting. Explosive charges will be optimized accordingly.
- Detailed records of blasting operations will be kept and blasting related impacts will be closely monitored.
- Modern blasting techniques will be employed to minimize vibration, including the use of millisecond delays with low charge weights, which will be determined based on geological formation and rock density.
- Blasthole counts and total charge per shot will be carefully optimized to comply with regulatory limits and minimize the risk of flyrock. To further protect potentially affected areas, both rubber and metallic blasting mats will be strategically deployed. During blasting activities will be kept on charge amounts, delays, and distance to blast sites, and resulting vibration levels. During blasting activities, compliance with the limit will be monitored in potential sensitive receptors.
- Blasting activities will adhere to the limit values specified in the Regulation on Environmental Noise Control for ground vibrations. Records of air shock and vibration measurements will be maintained, and compliance with regulatory limit values will be monitored to minimize impacts on local residents.
- The Project's grievance mechanism will be active for any complaints related to vibration impacts. Complaints will be thoroughly evaluated, and corrective actions will be implemented as necessary.
- Construction works will be designed and scheduled to minimize vibration and its adverse effects.
- Blasting will be carried out at designated times in order to prevent disturbance.
- Construction machinery and equipment will be operated by taking into account the recommended minimum working distances presented in Table XI.21.
- A specialized blasting team will be engaged to ensure safe and efficient operations.
- In locations where Potential Impact Zones are identified and cannot be mitigated through design or excavation changes, the contractor will implement tailored risk mitigation strategies.
- Modifying blast patterns and using low-risk techniques, such as reducing charge per delay, to minimize hazards.
- Damping ditches will be used to further reduce and attenuate vibrations for improved performance and stability.
- A blast attenuation survey will be carried out by the consultant to determine the distance at which vibration levels decrease to acceptable thresholds. If there is a Vibration Sensitive Structure located near or above the tunnels, all relevant factors will be carefully considered.
- The minimum charge per delay is set at 2 kg for 3 m hole (as common practice), which produces an effective impact radius of 56.96 meters from the blast site. If the distance between the blasting area and any cultural heritage site is less than 56.96 meters, all blasting activities must be suspended. In such cases, excavation and related operations must be carried out using mechanical equipment, such as excavators, instead of explosives.
- Seismographs will be installed to monitor ground vibrations and ensure that any blasting activity conducted at safe distances remains within acceptable vibration limits for every cultural heritage site less than 132.5 m of the nearest blasting location.

To safeguard cultural heritage sites that may be affected by vibration from blasting activities, a comprehensive set of mitigation measures has been developed (Table XI.36). These measures aim to preserve both the structural integrity and cultural significance of the sites, based on a thorough assessment of their sensitivity to vibration impacts. Key strategies include restricting the intensity of vibrations in proximity to heritage structures, conducting detailed inspections before and after blasting events, and employing advanced vibration-reducing technologies.

Customized risk mitigation approaches, such as modifying blast patterns and reducing charge sizes, will also be implemented to minimize potential damage to these sensitive locations. To establish a safe blasting distance near cultural heritage sites, the Peak Particle Velocity (PPV) equation (**3**) was utilized with specific parameters: a minimum charge per delay of 2 kg for 3 m hole (as common practice) and a PPV threshold of 5 mm/s, which is the limit considered safe for sensitive areas and substituting the constants by β= 1.605, K= 1884.9. The calculation is as follows:

$$D = \sqrt{W} * \left(\frac{K}{PPV}\right)^{\frac{1}{\beta}}$$

$$D = \sqrt{2} * \left(\frac{1884}{5}\right)^{\frac{1}{1.605}}$$

$$D = 56.96\ meters$$

The minimum safe blasting distance has been determined to be approximately 56.96 meters with a charge of 2 kg for 3 m hole (as common practice). Blasting will be strictly avoided within this range to prevent any potential damage to nearby heritage sites. Instead, material removal in this area will be carried out using excavators. Additionally, pilot blasting will be conducted at safe distances to validate vibration predictions and confirm the effectiveness of protective measures in place.

For blasting activities carried out at distances between 56.96 meters and 132.8 meters from the heritage sites, the maximum allowable explosive charge per delay for the post-mitigation will be calculated using the Peak Particle Velocity (PPV) equation (**3**), which has been rearranged to solve for charge weight (W):

$$W = \left(\frac{R}{\sqrt[\beta]{\frac{K}{PPV}}}\right)^2$$

Substituting the values β= 1.605, K= 1884.9 and PPV= 5 mm/s, the equation becomes:

$$W = \left(\frac{R}{\sqrt[1.605]{\frac{1884.9}{5}}}\right)^2$$

Table XI.38 presents post-mitigation calculations showing how the maximum allowable explosive charge per delay varies with distance to ensure that the 5 mm/s vibration threshold is not exceeded. After mitigation measures are applied, significantly larger charges can be used at safe distances. For example, at 132.5 meters from a sensitive area, up to 10.82 kg of explosives per delay can be safely detonated. However, the allowable charge still decreases sharply with reduced distance. At 56.96 meters, even post-mitigation, the charge must be limited to just 2 kg for 3 m hole (as common practice) to remain within the threshold.

Table XI.38 Post-mitigation calculations based on the distance to the risk point for a vibration of 5 mm/s

Distance to Risk Point (m)	Maximum Allowable Explosive Charge per Delay (kg) Without Exceeding the 5 mm/s Threshold Damage Limit
56.96	2.00
60.00	2.22
65.00	2.60
70.00	3.02
75.00	3.47
80.00	3.94
85.00	4.45
90.00	4.99
95.00	5.56
100.00	6.16
105.00	6.79
106.00	6.92
110.00	7.45
115.00	8.15
120.00	8.87
125.00	9.63
130.00	10.41
132.50	10.82

Based on the vibration threshold of 5 mm/s, the safe distances and corresponding maximum charge weights for sensitive areas are illustrated in Figure XI.54. According to the consultant's study, higher charges may be permitted where specialized mitigation measures, such as attenuation techniques and other vibration-reducing methods, are implemented.

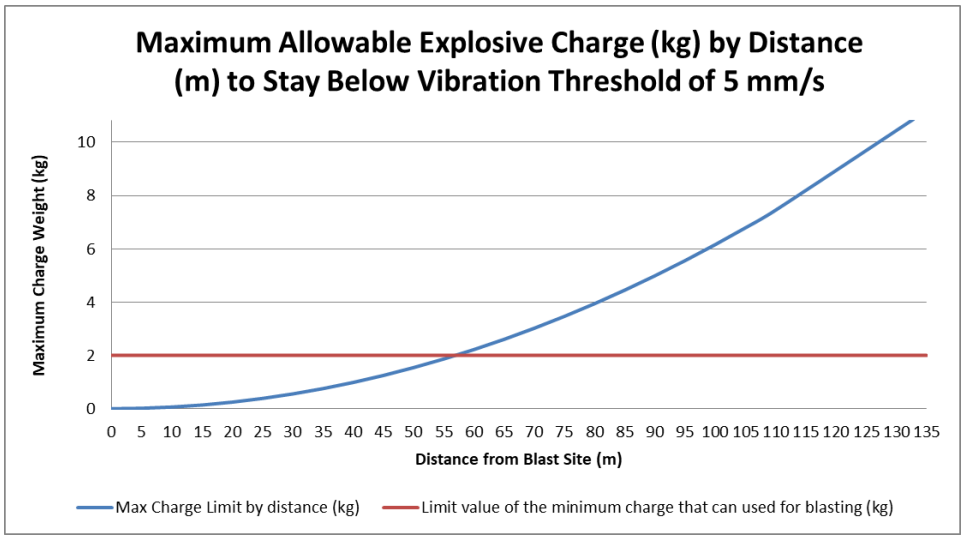

Figure XI.54 Maximum allowable explosive charge (kg) by distance (m) to stay below vibration treshold of 5 mm/s

However, if the distance between the blasting area and any cultural heritage site is less than 56,96 meters, all blasting activities must be suspended. In such cases, the site operations proceed using mechanical equipment such as excavators, rather than explosives.

Measurements of peak particle velocity (PPV) generated by drilling rigs and excavators indicate that all sites remain within acceptable vibration limits, with the exception of HRM 6. This site is currently pending a decision by the board, and therefore, no construction activity should take place.

XI.2.4.2. Operation Phase

If any complaint related to vibration is received through the Project's Grievance Mechanism, the complaint will be evaluated and corrective actions will be devised and implemented as necessary.

XI.2.5. Summary of Assessment and Residual Impacts

Land preparation and construction phase of the Project has the potential to cause vibration impacts as a result of activities such as heavy vehicle movement, piling, excavation, heavy earthworks, operation of vibratory equipment, demolition, and blasting. The assessment indicates that vibration from construction activities is likely to result in short term disturbance at nearby settlements with varying sensitivities. The residual impacts and assurance measures of cultural heritage sites that can be potentially impacted by the recommended charge per delay of 10.82 kg have been assessed in Table XI.36. However, these disturbances can be avoided and/or reduced by mitigation measures suggested above. Table XI.39 provides a summary of the vibration assessments. Residual impacts from construction-related vibration are expected to range from medium to low, depending on the sensitivity of the receptor and type of activity.

Table XI.39. Summary of Noise and Vibration

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Land Preparation and Construction Phase												
Increase in noise levels due to Project activities	Local Communities: Deniztepesi, Konaklı, Çakallar, Avsallar, Akdam, Karakaya, Hacıobası, Uzunlar, Sarıabalı, Sarılar, Bucakşeyhler, Kalemler, Ulukapı, Taşağıl,	Adverse	Local	Medium	Low	Short term reversible	Intermittent	Medium (B)	High (3)	High (B3)	• Equipment and machinery with lower sound power levels and noise-reduced models will be prioritized when possible and feasible. • Newer and/or well-maintained vehicles, machinery and equipment will be preferred for procurement. • Maintenance of construction machinery and equipment will be carried out regularly. • Silencers will be installed on appropriate machinery and equipment, including mechanical plants machinery and construction vehicle exhausts. • Portable barriers and acoustic enclosures will be installed around noise-generating stationary machinery, such as power generators, if necessary. • Speed limits for construction vehicles will be enforced, particularly near sensitive areas. • Traffic through residential areas will be minimized wherever possible. Dedicated site access roads will be constructed to reach Project components (campsites, the Motorway, quarries etc.) to avoid disturbances in residential areas when necessary.	Medium
	Local Communities: Serik, Emişbeleni, Sülek, Sağırin, Köprüçay, Bademliyar, Hacıali	Adverse	Local	Medium	Low	Short term reversible	Intermittent	Medium (B)	Moderate (2)	Medium (B2)	• According to the environmental monitoring plan under Project ESMS, noise monitoring will be conducted during the construction phase and the effect of noise in near neighborhoods will be controlled regularly. In case of any inconsistencies with regulation limits, measures will be immediately taken to diminish the noise levels and to satisfy the standards. • Potentially affected buildings sensitive to nighttime disturbances will be identified prior to construction, and nighttime construction works will be limited accordingly. • Any noise related complaints received through the Project's Grievance Mechanism will be assessed, and corrective actions will be implemented as necessary. • Construction vehicles will not be permitted to keep engines running while waiting to enter the site or waiting on-site. • Ancillary components in campsites, such as power generators, will be placed with consideration of potential noise disturbances. • The Motorway alignment will be used for transportation whenever feasible. • Roads used during the construction of the Motorway will be well maintained. • Site personnel will be trained to carry out construction activities using noise-reduction methods. • During the construction phase of the motorway in the Sarıabalı region, it was determined that the background noise levels increased by more than 3 dB(A) during daytime hours. It is therefore recommended that machinery and equipment to be used in this area be selected based on low noise emission criteria, and that regular noise monitoring be conducted to ensure compliance with applicable noise limits. • Noise monitoringis recommended for the Sarıabalı area. • A community consultation program will be initiated to inform the nearby residents, businesses and the local community when noise impacts are anticipated according to construction schedule.	Low
Increase in vibration emissions due to Project activities Blasting operations in quarries.	Local Communities Sarıabalı (AO-1) Borrow Pit (Sarıabalı) Dikmen Borrow Pit (HRM 20)	Adverse	Restricted	Medium	High	Short term irreversible	Intermittent	Wide (A)	High (3)	High (A3)	• Prior to the blasting operations, the sensitivity of nearby settlements/buildings against noise and vibration will be assessed. Buildings located within 100 meters of major vibration sources will be identified and assessed for vibration sensitivity prior to construction. Structural conditions of buildings located within 100 meters of the motorway alignment will be recorded before and after construction works to assess any possible vibration-induced damage. • One day before the blasting activities, the Turkish gendarmerie should be notified, announcements from the mosque should be done and protective barriers should be implamanted.	Medium

Definition of Potential Impact	Affected Ecosystem Component	Type of Impact	Impact Magnitude						Sensitivity/Value of Resource/Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
			Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Increase in vibration emissions due to Project activities Blasting operations in Tunnels	Local Communities Tunnel 1 (Sarıabalı), Tunnel 2 (HRM 8), Tunnel 3 (Taşağıl), Tunnel 4 (HRM 16)	Adverse	Restricted	Medium	High	Short term irreversible	Intermittent	Wide (A)	High (3)	High (A3)	During the entire construction phase, regular surveys will be carried out throughout blasting and drilling activities, capturing photographic records of all structures adjacent to blasting areas to detect and evaluate any damage that may occur post-blasting.Explosive charges will be optimized accordingly. Detailed records of blasting operations will be kept and blasting related impacts will be closely monitored • Explosive charges will be optimized accordingly. Detailed records of blasting operations will be kept and blasting related impacts will be closely monitored. • Modern blasting techniques will be employed to minimize vibration, including the use of millisecond delays with low charge weights, which will be determined based on geological formation and rock density. • Blasthole counts and total charge per shot will be carefully optimized to comply with regulatory limits and minimize the risk of flyrock. To further protect potentially affected areas, both rubber and metallic blasting mats will be strategically deployed. During blasting activities will be kept on charge amounts, delays, and distance to blast sites, and resulting vibration levels. During blasting activities, compliance with the limit will be monitored in potential sensitive receptors. • Blasting activities will adhere to the limit values specified in the Regulation on Environmental Noise Control for ground vibrations. Records of air shock and vibration measurements will be maintained, and compliance with regulatory limit values will be monitored to minimize impacts on local residents. • The Project's grievance mechanism will be active for any complaints related to vibration impacts. Complaints will be thoroughly evaluated, and corrective actions will be implemented as necessary. • Construction works will be designed and scheduled to minimize vibration and its adverse effects. • During the entire construction phase, regular surveys will be carried out throughout blasting and drilling activities by the contractor, capturing photographic records of all structures adjacent to blasting areas to detect and evaluate any damage that may arise post-blasting. Explosive charges will be optimized accordingly. • Blasting will be carried out at designated times in order to prevent disturbance. • In areas with identified or potential archaeological risk, archaeological excavations must be conducted and completed before the start of construction activities. Furthermore, all necessary documentation must be thoroughly prepared and submitted to the relevant authorities as part of the permitting process prior to initiating any excavation work.	Medium

Local Communities	Adverse	Restricted	Medium	Low	Short term irreversible	Intermittent	Restricted (C)	High (3)	Medium (C3)	• Construction machinery and equipment will be operated by taking into account the recommended minimum working distances presented in Table XI.21. • If blasting in close proximity to a settlement or sensitive site is deemed unavoidable, the blasting pattern shall be appropriately modified. This will include a reduction in the maximum charge per delay (kg), with the specific charge tailored to suit the distance and sensitivity of the surrounding area (Table XI.34 and Table XI.35). • A specialized external contractor will be engaged to ensure safe and efficient operations. • In locations where Potential Impact Zones are identified and cannot be mitigated through design or excavation changes, the contractor will implement tailored risk mitigation strategies. • Modifying blast patterns and using low-risk techniques, such as reducing charge per delay, to minimize hazards. • Damping ditches will be used to further reduce and attenuate vibrations for improved performance and stability. • A blast attenuation survey will be carried out by the consultant to determine the distance at which vibration levels decrease to acceptable thresholds. If there is a Vibration Sensitive Structure located near or above the tunnels, all relevant factors will be carefully considered. • A blast attenuation survey will be carried out by the consultant to determine the distance at which vibration levels decrease to acceptable thresholds. If there is a Vibration Sensitive Structure located near or above the tunnels, all relevant factors will be carefully considered. • The minimum charge per delay is set at 2 kg for 3 m hole (as common practice) , which produces an effective impact radius of 56.96 meters from the blast site. If the distance between the blasting area and any cultural heritage site is less than 56.96 meters, all blasting activities must be suspended. In such cases, excavation and related operations must be carried out using mechanical equipment, such as excavators, instead of explosives. • Seismographs will be installed to monitor ground vibrations and ensure that any blasting activity conducted at safe distances remains within acceptable vibration limits for every cultural heritage site less than 132.5 m of the nearest blasting location.	Low

Low

* *The impacts mentioned above have been assessed based on the worst-case scenario, and it is expected that the actual impacts will occur at lower levels with the implementation of the proposed noise and vibration mitigation measures.*

XII. CHAPTER – PROTECTED AREAS, LANDSCAPE AND VISUAL ENVIRONMENT

XII.1. Protected Areas

In order to identify and evaluate the protected areas within the Project area and its immediate vicinity, desktop studies and literature researches are carried out within the scope of the Project. For the works carried out, the sensitive area list available in Annex-5 of EIA Regulation (issued in Official Gazette No: 31907 dated July 29, 2022) is used as reference. This list covers areas that need to be protected in accordance with international conventions that Türkiye is contracting party and nationally declared protected areas.

Utilized data sources within the scope of the desktop studies are listed below:

- Database of Ministry of Agriculture and Forestry General Directorate of Nature Conservation and National Parks [1]
- Map of Prohibited and Open Hunting Areas in Antalya for years 2024-2025[2]
- Database of Ministry of Culture and Tourism[3]
- Database of General Directorate of Cultural Heritage and Museums
- Official letters and files that were obtained from relevant authorities
- kml / kmz files of the Project area and Google Earth Software

Protected areas around the Project are determined from above mentioned sources. The land use characteristics of the section were identified in the study area/corridor (having a total width of 400 meters being 200 meters on each side of the motorway axis) and there are no protected areas observed within the Project area. Other protected areas in Antalya Province, along with their locations and distances from the project area, are shown in

The Protected Areas Map of the Project Area is presented in **Error! Not a valid bookmark self-reference.**.

XII.1.1. Baseline Conditions

As mentioned above, sensitive area list available in Annex-5 of the EIA Regulation was used as reference to identify the protected areas around the Project area. Identified protected areas in accordance with sensitive area list are described below.

Areas Under Protection in Accordance with International Conventions that Türkiye is a Contracting Party

Some relevant conventions in this context can be listed as follows:

- Convention on the Conservation of European Wildlife and Natural Habitats" (Bern Convention)
- The Convention for the Protection of the Mediterranean Sea Against Pollution" (Barcelona Convention)
- Protocol Concerning Specially Protected Areas in the Mediterranean
- 100 Historic Sites of Common Mediterranean Interest announced by United Nation Environment Programme and selected in accordance with the Geneva Declaration
- World Cultural and Natural Heritage Convention
- The Convention on the Protection of Wetlands of International Importance as Waterfowl Habitat (RAMSAR Convention)
- European Landscape Convention

There are no protection areas in the Project area identified by any international convention/agreement, including the ones listed above, that Türkiye is signatory.

Protected Areas in accordance with National Legislation

a) "National Parks", "Nature Parks", "Nature Monuments" and "Nature Conservation Areas" identified in accordance with the second and third articles of National Parks Law

Antalya has eight parks in total, including four national parks and seven nature parks. The list of these parks is given in Table XII.1 below. İncekum Nature Park is the closest one among all others to the Project area and it is located 2 km south of corridor. Distances of the parks to the relevant sections of the route are also given in Table XII.1.

Table XII.1 List of National and Nature Parks in the Antalya Province

Name of National/Nature Park	Distance to the Closest Project Unit (km)	Direction with respect to the Closest Project Unit
İncekum Nature Park	2.0	South
Kurşunlu Waterfall Nature Park	10.3	West
Köprülü Canyon National Park	20.3	North
Altınbeşik Cave National Park	24.6	North
Güver Canyon Nature Park	32.6	West

Bey Mountains Coastal National Park	33.4	Southwest
Güllük Mountain Termesos National Park	35.7	West
Mavikent Nature Park	89.0	Southwest

There are twenty-one nature monuments near the project area. The list of these monuments is given in Table XII.2. Zeytintaşı Cave Nature Monument is the closest monument and it is located 7.4 km to the north of the corridor.

Table XII.2 List of Nature Monuments Near the Project Area

Name of Nature Monument	Distance to the Closest Project Unit (km)	Direct with respect to the Closest Project Unit
Zeytintaşı Cave	7.4	North
Kocain Cave	37.5	Northwest
Unnamed Nature Monument-1	42.5	North
Derebucak-Çamlık	53.3	North
Unnamed Nature Monument-2	57.0	Southwest
Unnamed Nature Monument-3	62.2	East
Altıkardeşler	78.1	East
Unnamed Nature Monument-4	78.6	Northeast
Unnamed Nature Monument-5	88.2	Southwest
Unnamed Nature Monument-6	92.3	Southwest
Unnamed Nature Monument-7	92.5	Southwest
Unnamed Nature Monument-8	101.1	Northeast
Unnamed Nature Monument-9	102.3	Southwest
Unnamed Nature Monument-10	102.7	Southwest
Unnamed Nature Monument-11	106.9	West
Unnamed Nature Monument-12	115.8	West
Unnamed Nature Monument-13	124.8	West
Unnamed Nature Monument-14	128.9	West
Unnamed Nature Monument-15	131.7	West
Unnamed Nature Monument-16	136.7	West
Unnamed Nature Monument-17	164.3	Southwest

There are three nature conservation areas in Antalya. The list of these conservation areas is given in Table XII.3. Kargı Village is the closest area and it is located 68.3 km to the northwest of the corridor.

Table XII.3. List of Nature Conservation Areas in the Antalya Province

Name of Nature Conservation Area	Distance to the Closest Project Unit (km)	Direction with respect to the Closest Project Unit
Dibek	67.8	Southwest
Çığlıkara	95.4	Southwest
Alacadağ	98.7	Southwest

b) “Wildlife Protection Areas, Wildlife Development Areas and Wild Animal Settlement Areas” identified in accordance with the Land Hunting Law.

There are eight wildlife development areas in Antalya province. There are also five wild animal settlement areas in Antalya province. Details on these areas are presented in Table XII.4 and Table XII.5, respectively.

Table XII.4 List of Wildlife Development Areas in the Antalya Province

Wildlife Development Area	Distance to the Closest Project Unit (km)	Direction with respect to the Closest Project Unit
Dimçayı	15.3	East
Üzümdere	19.6	North
Gündoğmuş	19.9	Northeast
Düzlerçamı	27.7	West
Sivridağ	38.1	West
Gidengelmez Mountain	49.2	North
Sarıkaya	61.9	Southwest
Kıbrıs Stream	124.9	Southwest

Table XII.5 List of Wild Animal Settlement Areas in the Antalya Province

Wild Animal Settlement Area	Direction with respect to the Closest Project Unit
Kaş Dristrict	Southwest
Kumluca District	Southwest
Serik District	North
Manavgat District	North
Gündoğmuş District	North

Prohibited and Open Hunting Areas in Antalya Province are presented in Figure XII.1.

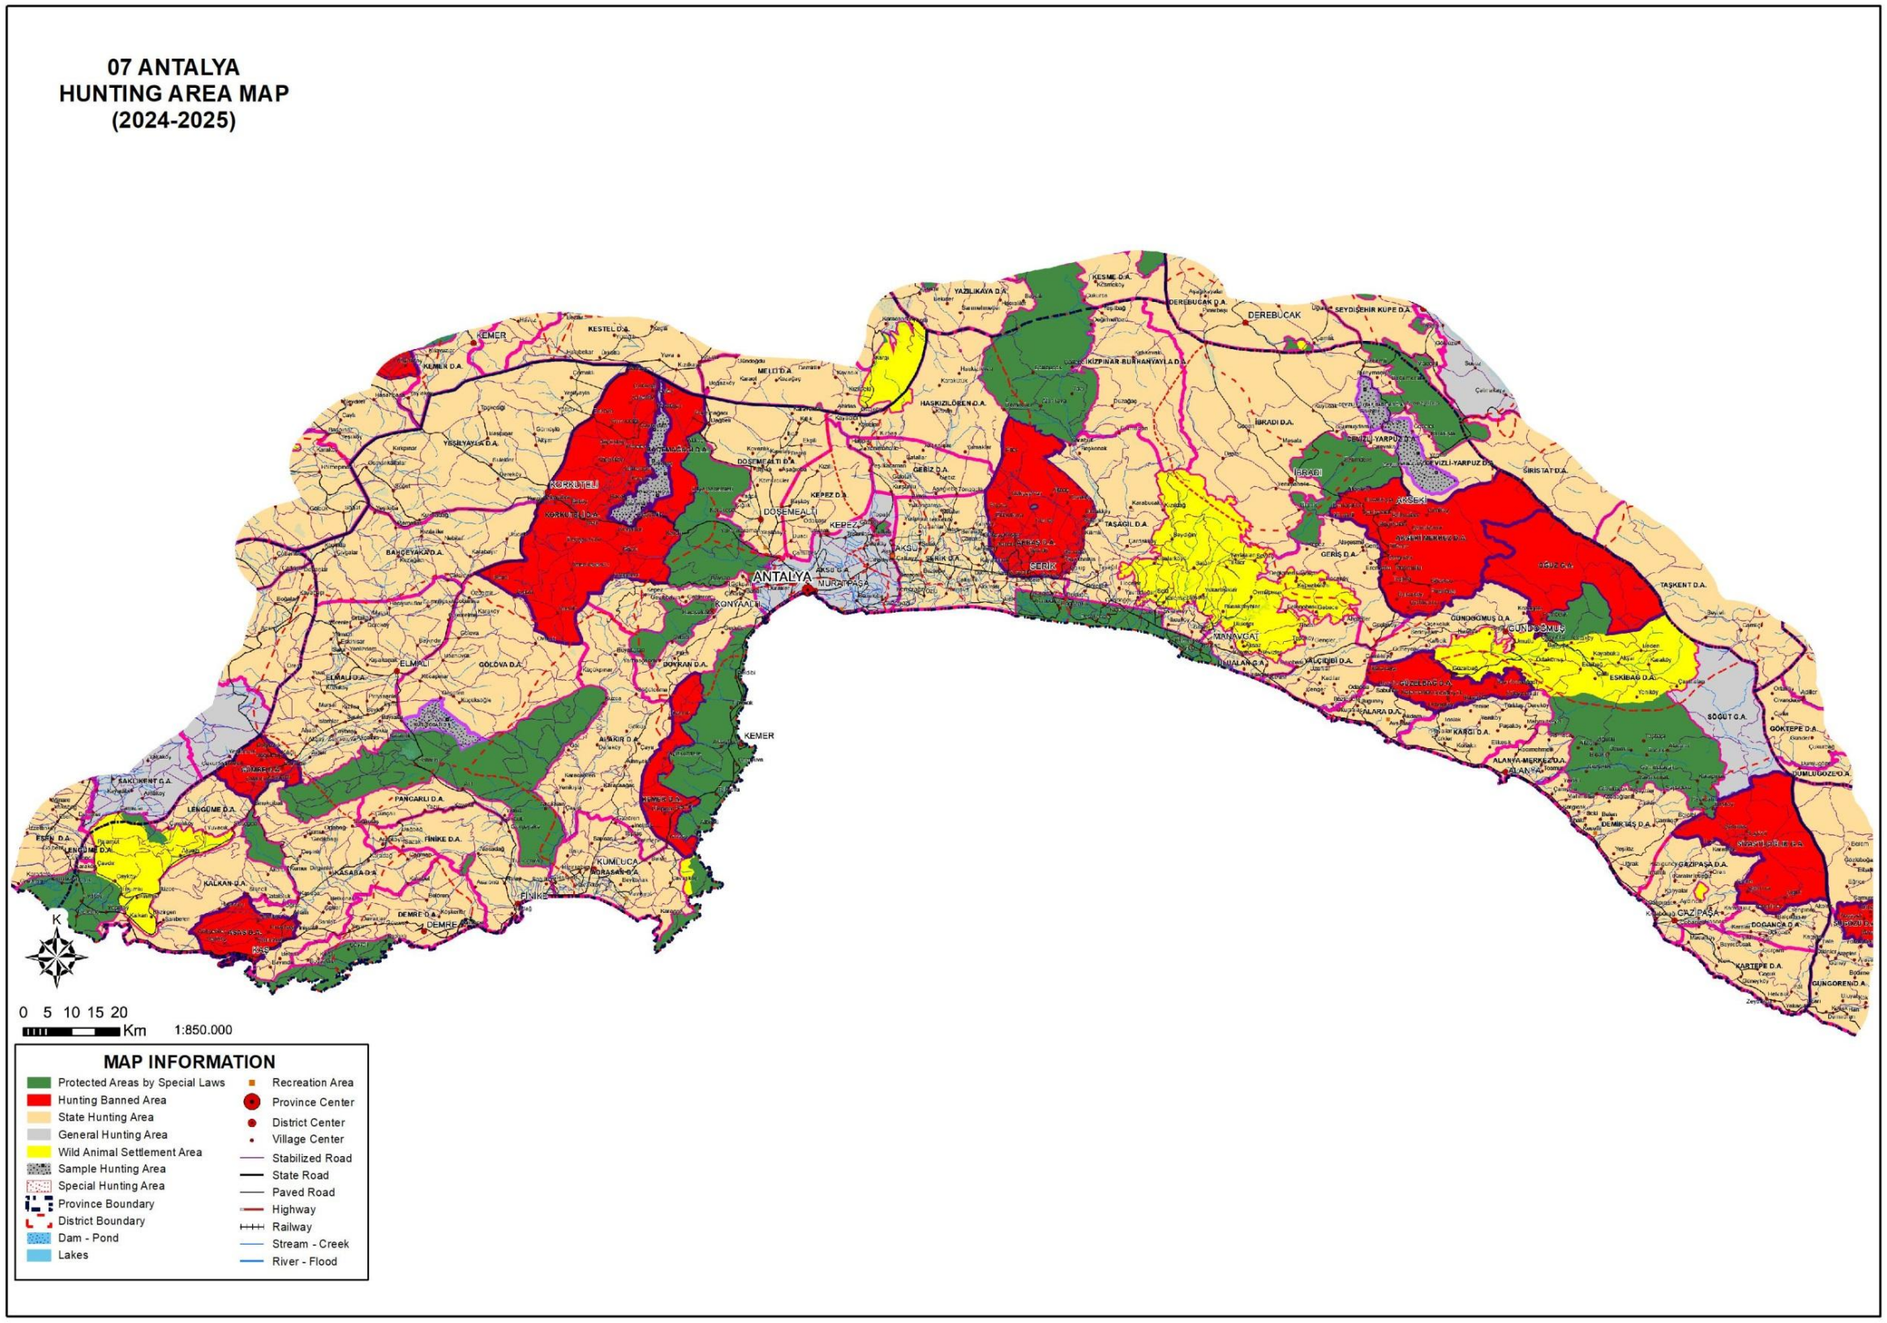

Figure XII.1 Prohibited and Open Hunting Areas in Antalya

c) Areas defined as “Cultural Property”, “Natural Property”, “Protected Site” and “Protected Area” according to 2863 numbered Law on Protection of Cultural and Natural Properties dated 23 July 1983, Article 3, Paragraph 1, Clause (a) (Definitions); Sub-clauses 1, 2, 3 and 5; and areas identified and registered in the same Law and amendments

A route survey was organized by the Project Sponsor together with the ENCON in order to understand the Project route. As a result of this field visit, cultural assets were seen within the Project Area.

Archaeological and immovable cultural heritage within the scope of the ESIA process are being conducted by the expert group of HERMES Archeology & Environmental and Social Consultancy Company between 26th of August and 8th of September in 2024 and 14th and 17th of March 2025.

Further detailed information about Cultural Heritage regarding the Project and potential impact area will be given in Chapter XIII (“Archaeological and Immovable Cultural Heritage”) after the relevant assessments are made.

Köprüçay Basin Natural Protected Area is partially inside of the Project area.

Further detailed information about biodiversity regarding the Project and potential impact area will be given in Chapter IX (“Ecology and Biodiversity”) after the relevant assessments are made.

d) Aquaculture Production and Breeding Sites within the scope of Fisheries Laws and Regulations.

Article 34 of the Communiqué No. 5/1 on the Regulation of Fishing for Commercial Purposes (Communique No: 2020/20) lists the inland water bodies where hunting is completely forbidden. Inland waters where hunting is completely prohibited for Antalya province are listed below.

- Dim Dam Lake
- Gökçeler Dam Lake
- Manavgat Dam Lake
- Naras Dam Lake
- Oymapınar Dam Lake

Annex-7 of the same communique lists streams within a distance of 500 meters from the sea in the stream directions where aquaculture is prohibited. These waterbodies for Antalya Province are also listed below with their respected districts.

- Acısu (Karaçay), Akçay streams - Finike District
- Aksu Stream - Aksu District
- Alakır Stream - Finike and Kumluca Districts Border
- Alara Stream - Alanya and Manavgat Districts Border
- Boğaçayı – Konyaltı District
- Dimçayı - Alanya District
- Duden Stream – Muratpaşa District
- Eşen Stream - Fethiye and Kaş Districts Border
- Kaledıran Stream - Anamur and Gazipasa Districts Border
- Kargı Stream - Alanya District
- Köprü Stream - Serik and Manavgat Districts Border
- Manavgat River - Manavgat District

According to this communique, in places identified as sea turtle breeding areas (for Antalya Province; Patara, Demre, Kumluca, Tekirova, Belek, Kızılot, Gazipaşa, Demirtaş, Olympos-Çıralı) I (a) group mining is prohibited. These mining activities are involved in the Project since they cover the mining of the sand and gravel used in construction and road construction and found naturally in nature. Annex-4 of the Communiqué No. 5/2 on the Regulation of Fishing for Amateur Purposes (Communique No: 2020/21) lists the inland water bodies where hunting is completely prohibited. Inland waters where hunting is completely prohibited for Antalya province are listed below.

Bıçkıcı Stream – Gazipaşa District
Çığlık Stream - Gazipaşa District
Delice Stream - Gazipaşa District
Avlan Lake – Elmalı District
Üzümdere – Alanya District

Annex-5 of the same communiqué lists the inland water bodies where hunting is partially prohibited. Inland waters where hunting is partially prohibited for Antalya province are given in the Table XII.6.

Table XII.6 Inland Waters where Hunting is Partially Prohibited in Antalya Province

Prohibition Boundaries	Stream Name	District
Köprülü Canyon National Park Düzyer location in the southwest of Çaltepe Village, the section from the borders of the National Park to Olukköprü	-	Manavgat District
The region starting from Akbiladan Stream in the south of Kalecik Village to Ali Bridge in the direction of water flow	Alara Stream	Alanya District
The section starting from Sıçanlı Plateau Yavuşan Stream, which is the origin point of the stream, to the junction of Taşatan Stream with Derince Stream in the direction of water flow	Kargı Stream	
1st Branch Stream origin point, following Gavurdaşı Stream, 2nd Branch origin point, following Kuru Stream and Derinkoyak Stream, following Dim stream flow direction until Bucakköy Neighborhood bridge	Dim Stream	
The section starting from the origin point of the stream, Erenler içi, following the canyon in the direction of flow until the intersection of the stream coming from Cinali Neighborhood	Sapadere Stream	
From the point where the İkizpınarı Stream in Değirmenözü Village Boğazkavak Neighborhood of Köprülü Canyon National Park joins the Köprüçay, Boyalıçay, Kırgeçit Stream, Kocadere, Akçay Stream, including Gökçesu spring, up to Karabük Village Bridge	Boyalıçay, Kırgeçit Stream, Kocadere, Akçay Stream, Gökçesu	
Starting from the place where the stream is originated, the section up to Kabakbükü in the direction of the flow of the stream	Direnli Stream	Gazipaşa District
The part from Aşağı Karaman Neighborhood to the junction with Doyran Stream	Karaman Stream	

None of the abovementioned areas are within the Project area and therefore the Project is not expected to have any impacts on them within the national legislation.

e) Areas defined in the relevant articles of the Water Pollution Control Regulation

Since the 17th, 18th, 19th and 20th Articles in Water Pollution Control Regulation were repealed; the Regulation on the Protection of Drinking-Potable Water Basins was taken as a reference in order to determine the basin protection limits for drinking water reservoirs. According to the Antalya Province Environmental Status Report for 2023, water dams used for drinking purposes within Antalya province are listed in Table XII.7.

Table XII.7 List of Water Dams used for Drinking Purposes in the Antalya Province

Name of Dam	Distance to the Closest Project Unit (km)	Direction with respect to the Closest Project Unit
Manavgat Dam	2.0	Northeast
Oymapınar Dam	8.8	North
Alanya Dim Dam	21.0	East
Karacaören II Dam*	40.7	Northwest

**Karacaören-II Dam is located outside the borders yet it is used for drinking purposes in the Antalya Province.*

f) Areas in accordance with the scope of Air Quality Assessment and Management Regulation

According to the 7th Article of Air Quality Assessment and Management Regulation, zones and sub-zones for air quality identification are listed in Annex-I of Memorandum 2013/37. This memorandum divides Türkiye into various zones and sub-zones to identify pollution profiles of provinces by the MoEUCC. According to the evaluations made by the Ministry in this extent in Annex-III, Antalya is included in the “high pollution potential provinces” list.

g) Areas determined and declared as "Specially Protected Environment Area" by the President of the Republic pursuant to Article 9 of the Environment Law

Belek Specially Protected Environment Area is partially inside of the Project area and it is to the south. There is also Kaş-Kekova Specially Protected Environment Area, Patara Specially Protected Area and Fethiye-Göçek Specially Protected Environment Area to the southwest, with a distance of 120.5 km, 152.4 km and 157.9 km from the Project area, repectively.

h) Areas under protection according to the Bosphorus Law,

There are no protected areas within the scope of Bosporus Law in the Project area.

i) Areas considered as forest areas in accordance with the Forest Law,

The Project falls within the jurisdiction of four (4) different Forestry Management Directorates (Serik, Taşağıl, Manavgat and Alanya) under Antalya Regional Directorate of Forestry as summarized in Table XII.8.

Table XII.8 Relevant Forestry Directorates for the Project

Regional Directorate	Forestry Management Directorate	Management Sub-directorate
Antalya Regional Directorate of Forestry	Serik Forestry Management Directorate	Serik Forestry Management Sub-directorate
		Akbaş Forestry Management Sub-directorate
	Taşağıl Forestry Management Directorate	Taşağıl Forestry Management Sub-directorate
		Çardak Forestry Management Sub-directorate
	Manavgat Forestry Management Directorate	Şelale Forestry Management Sub-directorate
		Naras Forestry Management Sub-directorate
		Manavgat Forestry Management Sub-directorate
		Yalçıdibi Forestry Management Sub-directorate
	Alanya Forestry Management Directorate	Alara Forestry Management Sub-directorate
		Avsallar Forestry Management Sub-directorate
		Kargı Forestry Management Sub-directorate

According to CORINE (2018) database, forestlands (including the broad-leaved forests, coniferous forest and mixed forest) cover 10.5% (722.65 ha) of the entire study corridor (6,856.13 ha).

According to STATIP (2015) database, forestlands (including the broad-leaved forests, coniferous forest, mixed forest and shrublands) cover 29.1% (1,991.45 ha) of the entire study corridor (6,856.13 ha).

According to GDRS (1993) database, forestlands cover 14.4% (988.19 ha) of the entire study corridor (6,856.13 ha).

Analyses such as canopy cover classifications and forest stand types of the forests in the project area using Forest Management Plans will be carried out by determining the expropriation corridor and will be given in Chapter V.

j) Areas where construction is prohibited in accordance with the Coastal Law,

There are no areas subject to construction ban in accordance with the Coastal Law.

k) Areas specified in the Law on the Breeding of Olive Groves and Grafting of Wild Olives,

There are no areas designated in accordance with Law on Improvement of Olive Cultivation and Grafting of Wild Species.

l) Areas specified in the Pasture Law,

According to CORINE (2018) database, pasturelands are not present within the study corridor. According to STATİP (2015) database, pasturelands are 3.31% for the Project and total area of pastureland is 227.04ha. According to GDRS (1993) database, pasturelands are 0.31% for the Project and total area of pastureland is 21.09 ha. The pasture areas included in the STATİP 2015 data are within the scope of the Pasture Law No. 4342. It should be noted that; in this study, regardless of whether it is within the scope of the Law or not, the land is determined based on its current use according to its natural structure. Detailed assessment will be given in Chapter V.

m) Areas specified in the Regulation on the Protection of Wetlands.

There are one nationally important and three locally important wetlands in Antalya province according to the List of Wetlands of International Importance of Türkiye. These wetlands and their distances to the Project route are also given in Table XII.9 and Table XII.10, respectively below.

Table XII.9 List of Nationally Important Wetland Areas in the Antalya Province

Nationally Important Wetland Area	Distance to the Closest Project Unit (km)	Direction with respect to the Closest Project Unit
Avlan Lake	88.9	Southwest

Table XII.10 List of Locally Important Wetland Areas in the Antalya Province

Locally Important Wetland Area	Distance to the Closest Project Unit (km)	Direction with respect to the Closest Project Unit
Eğri Lake	41.3	Northeast
Baymelek Lagoon	103.4	Southwest
Demre Çayağzı Bird Paradise	116.3	Southwest

The Protected Areas Map of the Project Area is presented in **Error! Not a valid bookmark self-reference.**.

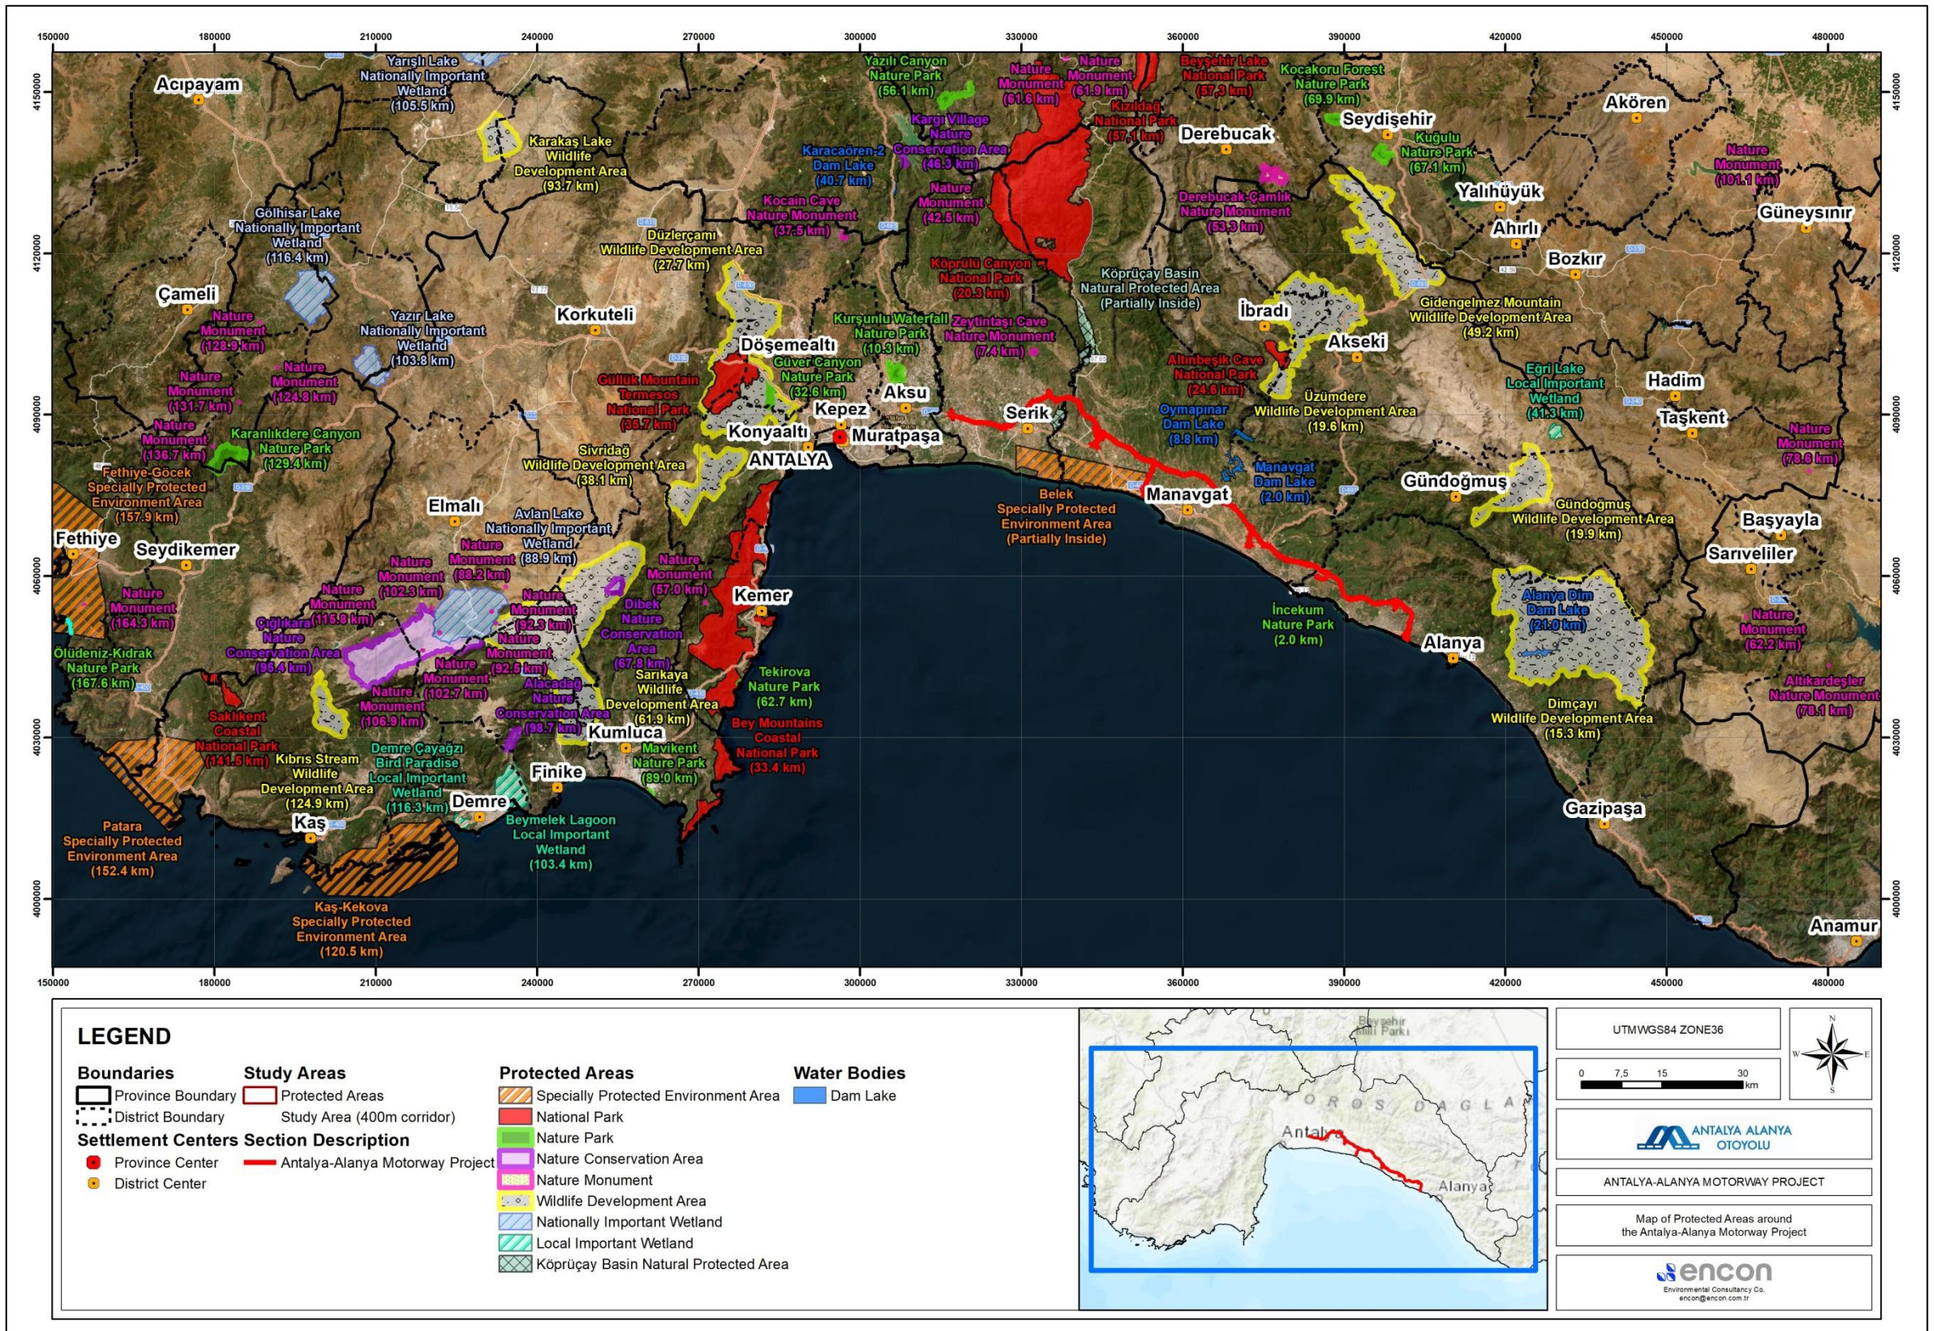

Figure XII.2 Protected Areas Map of the Antalya Province

n) Areas identified in the approved Environmental Plans as areas whose existing characteristics are to be preserved and where construction is prohibited (natural character to be preserved, biogenetic reserve areas, geothermal areas and similar).

According to Antalya-Burdur-Isparta Region Environmental Plan there are no construction prohibited areas in the region.

o) Agricultural Areas: Agricultural development areas; irrigated, irrigable and land use capability classes I, II, III and IV areas; all of the class I and II and special crop plantation areas used in rainfall-dependent agriculture.

Table XII.11 provides an overview of the land use capabilities of the agricultural areas within the study corridor. As can be seen, in the Table XII.11, a major part (36.3%) of the agricultural lands consists of soils having Class II land use capability. Class II lands are decent lands that can only be processed after taking some special precautions. Their difference from Class I lands is one or more of the limiting factors such as slight slope, moderate exposure to erosion, moderately thick soil, exposure to occasional moderate floods and a moderate level of moisture that can easily be isolated.

Table XII.11 Land Use Capabilities of the Agricultural Areas within the Study Corridor (according to Turkish General Directorate for Rural Services, 1993)

Land Use Capability Class	Area (m^2)	Area (ha)	Percent (%)
Class I	4,599,930.62	459.99	12.27
Class II	13,599,393.62	1,359.94	36.28
Class III	8,095,488.95	809.55	21.60
Class IV	5,346,802.43	534.68	14.27
Class VI	5,838,424.14	583.84	15.58
Total:	**37,480,039.76**	**3,748.00**	**100.00**

Wetlands: Natural or artificial, permanent or temporary, stagnant or flowing, fresh, brackish or salty, covering depths not exceeding 6 meters during the ebb and flow of the tidal movement of the seas, all waters, marshes, reeds and peatlands that are important as a habitat for living things, especially water birds, and places that are ecologically wetlands from the coastal edge line of these areas towards the land side.

The wetlands in the Antalya Province are given in Table XII.9 and Table XII.10, and also shown in

The Protected Areas Map of the Project Area is presented in **Error! Not a valid bookmark self-reference.**.

Dim Stream	Obaçay
Düden Stream	Salamur Stream
Eşen Stream	Sedre Stream

r) Areas which are important for scientific research and/or habitats of threatened or endangered species and species endemic to our country, biosphere reserves, biotopes, biogenetic reserve areas, areas with unique geological and geomorphological formations.

According to Antalya-Burdur-Isparta Region Environmental Plan there is no such area in the region.

XII.1.2. Potential Impacts and Mitigation Measures

Project development aims to avoid any significant impact on any protection area or area of environmental, social and cultural importance. In this regard, direct potential impacts on protected areas are assessed by field survey and GIS techniques. The potential impacts of the Project on any protection areas will be mitigated through either changing the route of the Motorway or other design changes. Potential impacts on the protected areas, and protection of these areas is one of the main criteria being considered in the route selection process.

Based on the findings of the ongoing studies, changes may be made in the route of the Project as a mitigation measure. Detailed information about further optimization studies in this area are provided in Chapter **Error! Reference source not found.** (“Analysis of Alternatives”) after relevant assessments are made based on the field survey.

By the above mentioned revisions and adjustments, the potential significant impacts on the protected areas will be avoided or mitigated to acceptable levels.

XII.2. Landscape and Visual Environment

The Motorway itself and its large components such as viaducts, toll plazas, and service areas will be a source of change in the existing visual environment. Because of the experiential nature of visual resources, the human response to visual changes in the landscape cannot be quantified, even though the visual changes associated with a development can be described (Hankinson 1999). The areas having unique or high landscape value, such as national parks, nature parks or natural forests, recreational areas, etc., are generally the ones that are most important with regard to potential visual effects of the Motorway and its components. The Project route selection has been done in due consideration of the protected areas, where a significant distance has been maintained with the Motorway components and the protected areas.

XII.2.1. Assessment Methodology and Data Sources

The Project information including route maps, locations of structures were reviewed together with the available literature regarding the conditions in the area.

The assessment addresses the whole Project components including the Motorway route and related facilities. In this context, in addition to the route, the assessment will consider the following elements:

- Toll Plazas
- Interchanges and access roads
- Viaducts and bridges
- Quarries and Campsites

Based on the assessment, mitigation measures are recommended for the purpose of integrating the Motorway into the wider landscape. The mitigation measures will be in the form of proposed Motorway planting and will also serve to visually screen the Motorway from nearby viewers, mainly residents of nearby neighborhoods.

Significance Criteria

The significance criteria for the impacts on landscape and visual environment is determined, as high, medium or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter 4 (“ESIA Methodology”) is used for the determination of the magnitude of impact on landscape and visual environment. Sensitivity/value criteria used in the scope of impact assessment are summarized in Table XII.13.

Table XII.13 Criteria for Sensitivity/Value of Resource/Receptor

Ecosystem Component	Sensitivity/Value Level		
	High (3)	Medium (2)	Low (1)
Landscape	Natural landscape character areas	Semi-natural landscape character areas (e.g. undeveloped rural settlement areas)	Unnatural and/or semi-natural landscape character areas (e.g. developed rural settlement areas, urban areas)
Visual Environment (Residents of Settlements)	Settlements located at a distance between 0-400 meters from Motorway Axis and visual impact occurance according to topography, artificial and natural barriers	Settlements located at a distance between 400-700 meters from Motorway Axis and visual impact occurance according to topography, artificial and natural barriers	Settlements located at a distance between 700-1000 meters from Motorway Axis and visual impact occurance according to topography, artificial and natural barriers

XII.2.2. Baseline Conditions

The landscape of the study area has been analyzed and described in terms of the key features and overall character via Google Earth. The landscape characteristics around the Project Route are identified with reference to the Motorway KMs in Table XII.14 below.

Table XII.14 Landscape Characteristics around the Motorway Route

Km Chainage	Description
52+000 / 56+000	**Flat Agricultural Lands in Deniztepesi and Sarıabalı Neighborhoods** This section is located at the beginning of the Motorway route. The area consists mostly of flat agricultural lands, greenhouse areas, rural settlements and some residences of Deniztepesi Neighborhood. The southwest of this section is urbanized starting from a distance of approximately 6 km. Serik Junction near Deniztepesi and Sarıabalı neighborhoods are located in this section. Köprüçay also passes through the region. There are agricultural areas, greenhouse areas and some residences on the banks of Köprüçay in Sarıabalı Neighborhood.
56+000 / 66+000	**Sloping Forest Lands in Çakış, Sağırin and Taşağıl Neighborhoods** In this section of the Motorway route, there are sloping forest lands and agricultural lands on the slopes of the hills, as well as agricultural lands on the plains in Taşağıl Neighborhood.
66+000 / 70+500	**Flat Agricultural Lands in Hocalar and Gündoğdu Neighborhoods** In this section of the Motorway route, the entire area consists of flat agricultural lands. In Yavrudoğan Neighborhood, sloping forest lands on the slopes of the hills are noteworthy. Taşağıl Junction near Hocalar Neighborhood is located in this section.
70+500 / 88+000	**Flat Agricultural Lands in Çolaklı, Ilıca and Manavgat Neighborhoods** In this section of the Motorway route, the whole area consists of flat agricultural land, wooded areas on the slopes of hills and some houses belonging to neighborhoods. Manavgat Junction near Yukarıışıklar Neighborhood is located in this section. Along the connection road to Manavgat Junction, urban settlements are dense and there are also agricultural areas and greenhouse areas. Manavgat Stream also passes through the area.
88+000 / 90+500	**Flat Agricultural Lands in Doğançam, Karacalar and Kızılağaç Neighborhood** In this section of the Motorway route, there are sloping forest lands on the slopes of the hills and agricultural lands on the plains, as well as a few residential areas belonging to the Doğançam Neighborhood.
90+500 / 100+000	**Flat Agricultural Lands in Kızılot and Çenger** In this section of the Motorway route, the entire area consists of flat agricultural land and forest areas on the slopes of hills. The Manavgat Interchange near Yukarıışıklar neighborhood is located in this section. There are a few greenhouses with larger areas in this section of the route.
100+000 / 104+000	**Sloping Forest Lands in Hacıisalı and Hacıobası Neighborhoods** In this section of the Motorway route, there are sloping forest lands on the slopes of the hills and agricultural lands on the plains. Manavgat East Junction near Hacıisalı Neighborhood is located in this section.
104+000 / 120+000	**Flat Agricultural Lands in Çavuşköy, Kadılar, Örenşehir, Yalçıdibi, Odaönü, Karakaya and Çakallar, Karamanlar Neighborhoods** In this section of the Motorway route, the entire area consists of flat agricultural lands, greenhouse areas, wooded areas on the slopes of hills and residential areas belonging to neighborhoods. Alarahan Junction near Çakallar Neighborhood is located in this section.
120+000 / 125+500	**Sloping Forest Lands in İncekum and Avsallar Neighborhoods** In this part of the Motorway route, sloping forest lands are predominant on the slopes of the hills. There are also greenhouse areas on the plains of Avsallar Neighborhood.
125+500 / 136+000	**Sloping Forest Lands in Akdam, Türkler, Soğukpınar and Toslak Neighborhoods** In this section of the Motorway route, there are sloping forest lands on the slopes of the hills, as well as greenhouse areas on the plains of Akdam, Türkler, Soğukpınar and Toslak Neighborhoods, and scattered houses within these areas. The Konaklı Junction near the Soğukpınar Neighborhood is located in this section. Along the Konaklı Junction connection road, greenhouse areas are dense and residential areas are also located on the route.

XII.2.3. Visibility Analysis

In the visibility studies, 62 settlements within the socio-economic area of impact were taken into account, and the visible and nonvisible regions from these settlements were mapped via ArcGIS. These settlements are classified in Table XII.15 according to their visibility levels of the Motorway in three categories as fully visible, partially visible and nonvisible.

Table XII.15 Visibility of the Project from each Settlement

Visibility Degree of the Project from the Settlements	Settlements
Fully Visible	Aşağıçatma, Çakallar, Kayaburnu, Kızılot, Kökez, Merkez (Serik), Sarılar, Soğukpınar, Sülek, Üründü, Uzunlar,
Partially Visible	Akdam, Alara, Aşağıışıklar, Avsallar, Bucakşeyhler, Deniztepesi, Dikmen (Manavgat), Dolbazlar, Emişbeleni, Evrenleryavşı, Gültepe, Gündoğdu, Hacıali, Hacıisali, Hacıobası, Hatipler, Hocalar, Ilıca, Kalemler, Karakaya, Karaöz, Konaklı, Örenşehir, Sağırin, Side, Şişeler, Taşağıl, Toslak, Türkler, Ulukapı, Yavrudoğan, Yeniköy, Yukarıışıklar,
Nonvisible	Aksaz, Aşağıkocayatak, Burmahancı, Çakış, Çandır, Çavuşköy, Cevizler, Cumalı, Demirciler, Dikmen (Serik), Elikesik, İncekum, Kadılar, Karacalar, Odaönü, Sarıabalı, Yalçıdibi, Yukarıkocayatak,

Example visibility maps for residential areas where the Project is fully visible, partially visible and nonvisible are presented in
Figure XII.3,
Figure XII.4 and
Figure XII.5, respectively. Visibility maps prepared for the remaining settlements are presented in Annex-4.

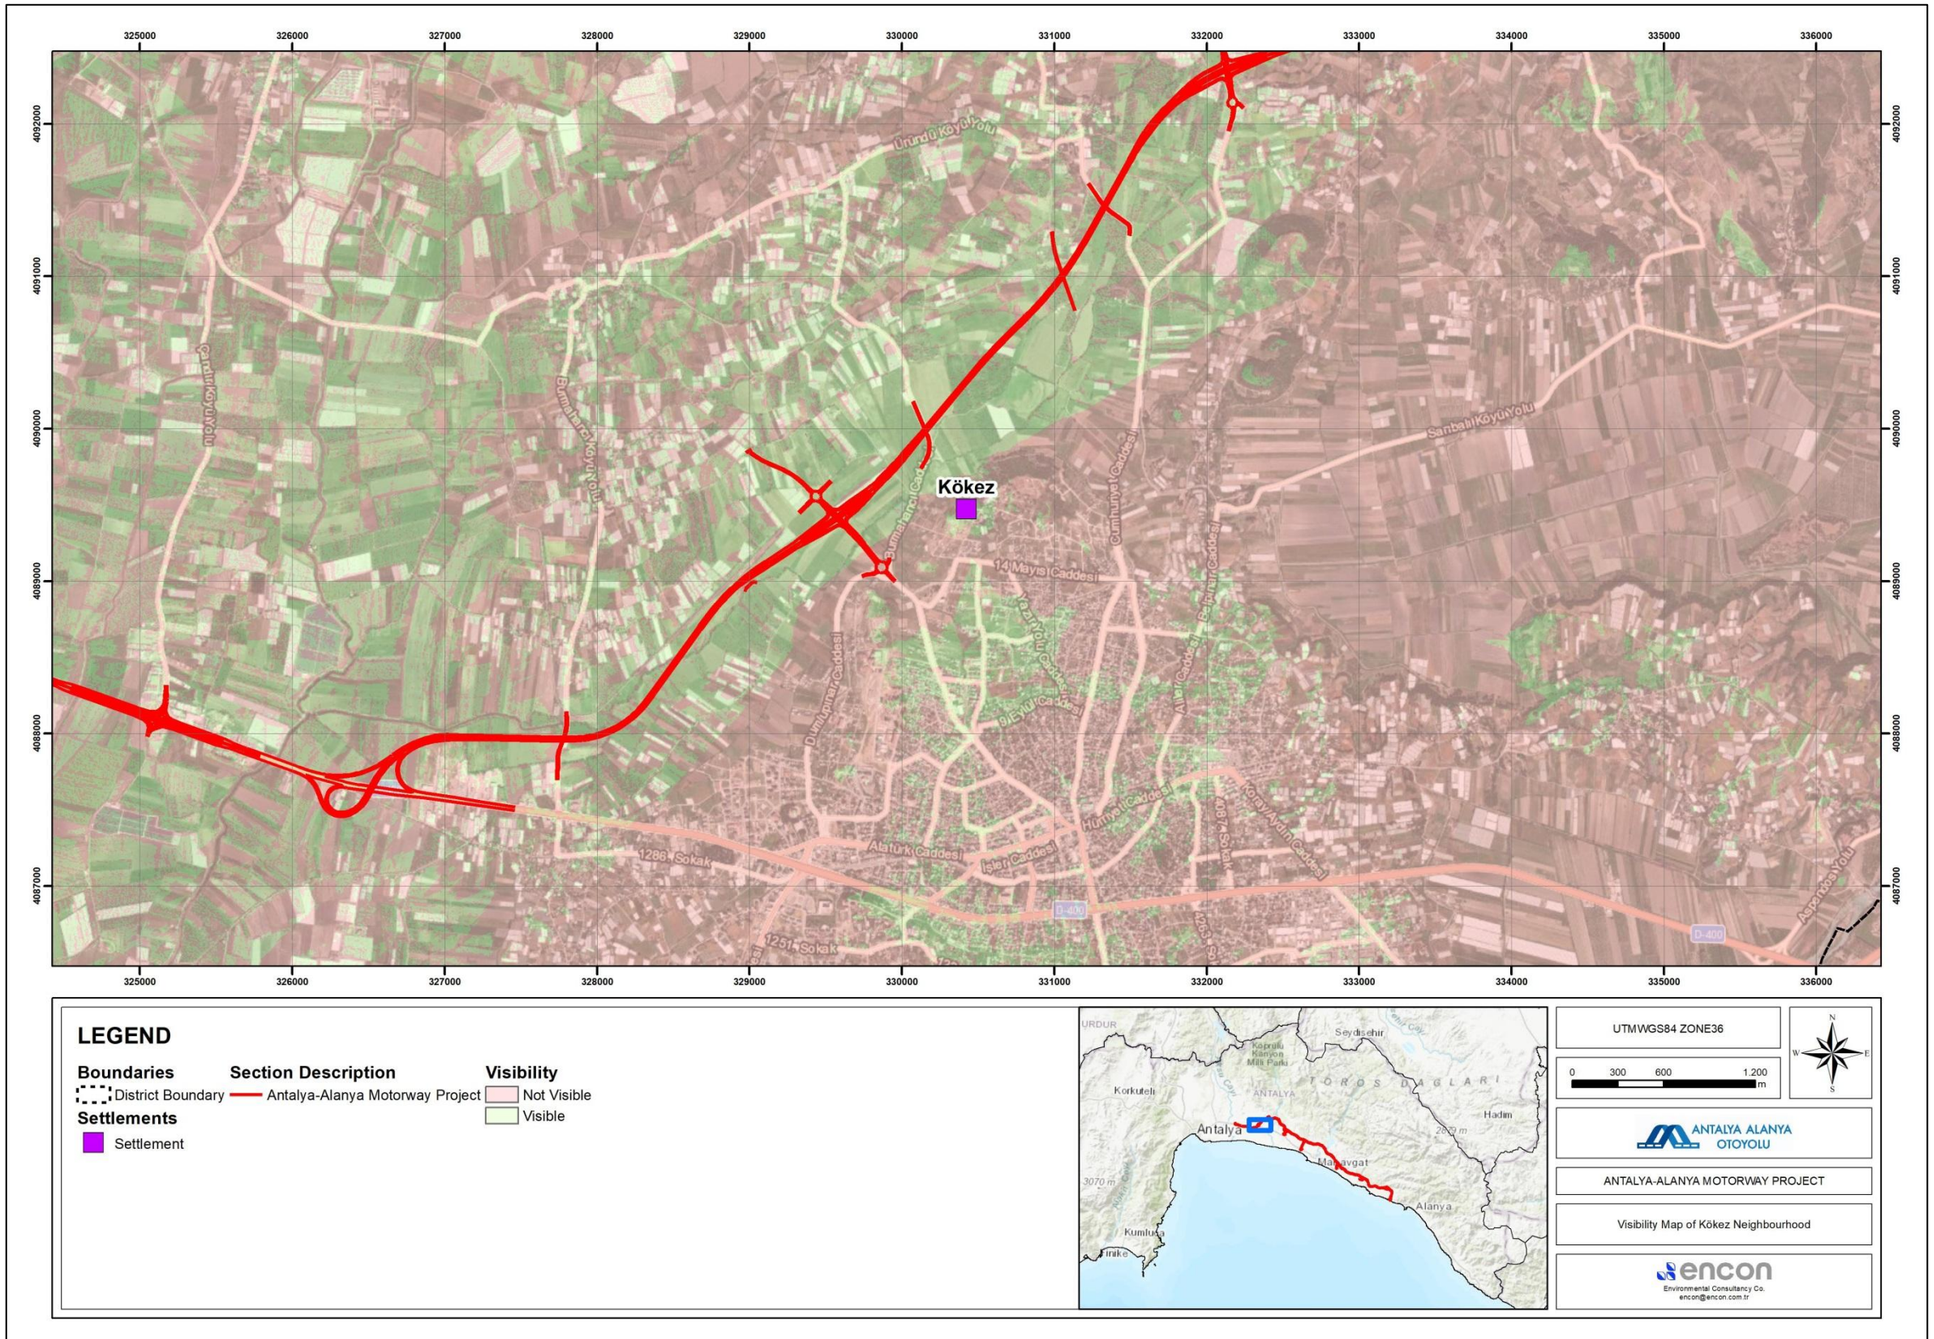

Figure XII.3 Visibility Map of Kökez Neighbourhood for the Project Route (Fully Visible)

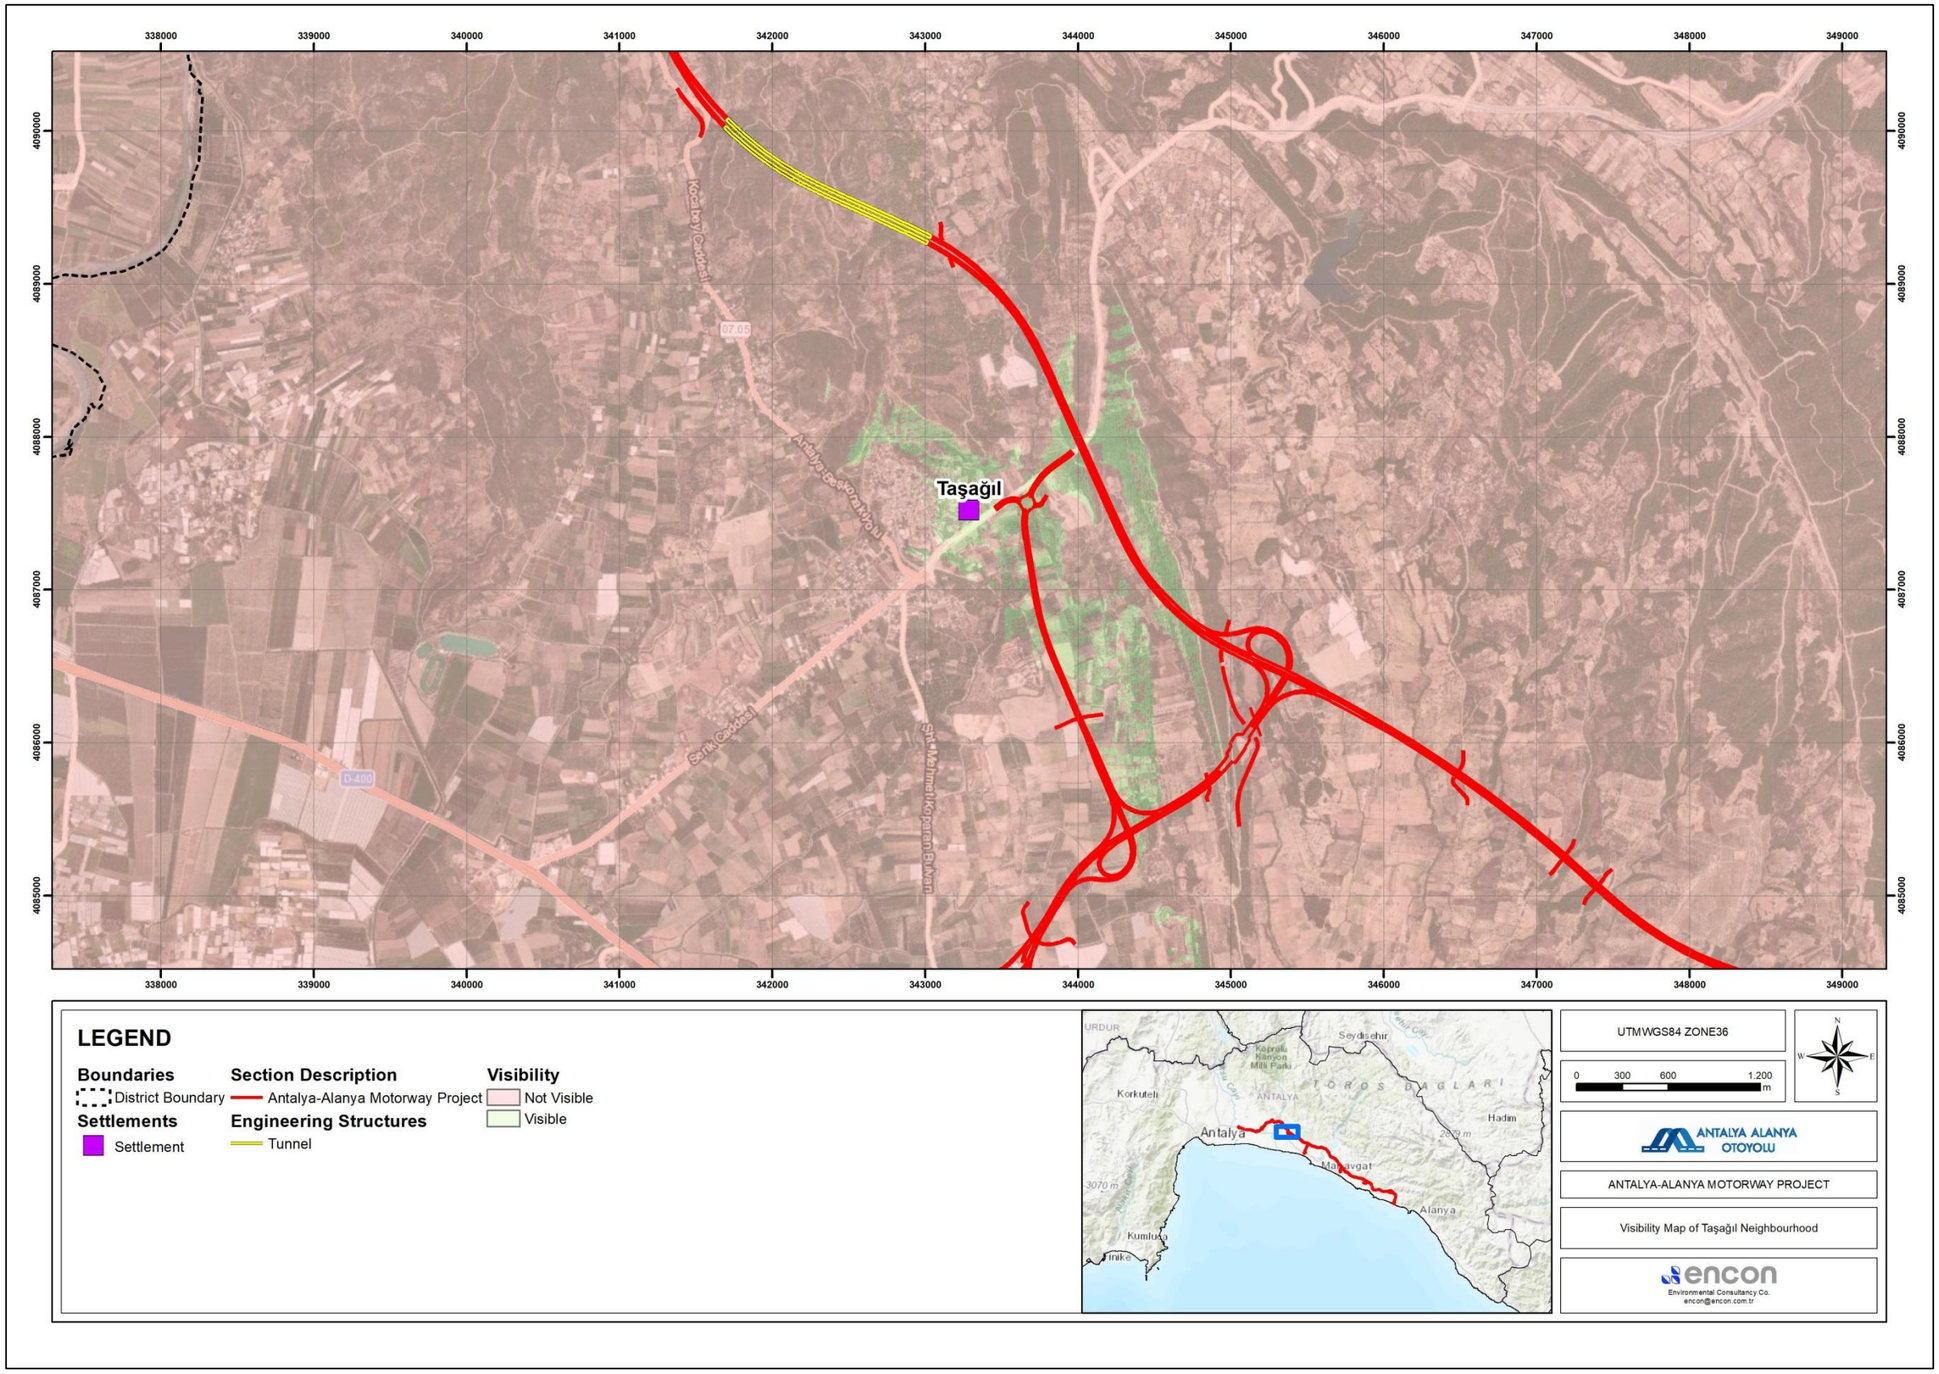

Figure XII.4 Visibility Map of Taşağıl Neighbourhood for the Project Route (Partially Visible)

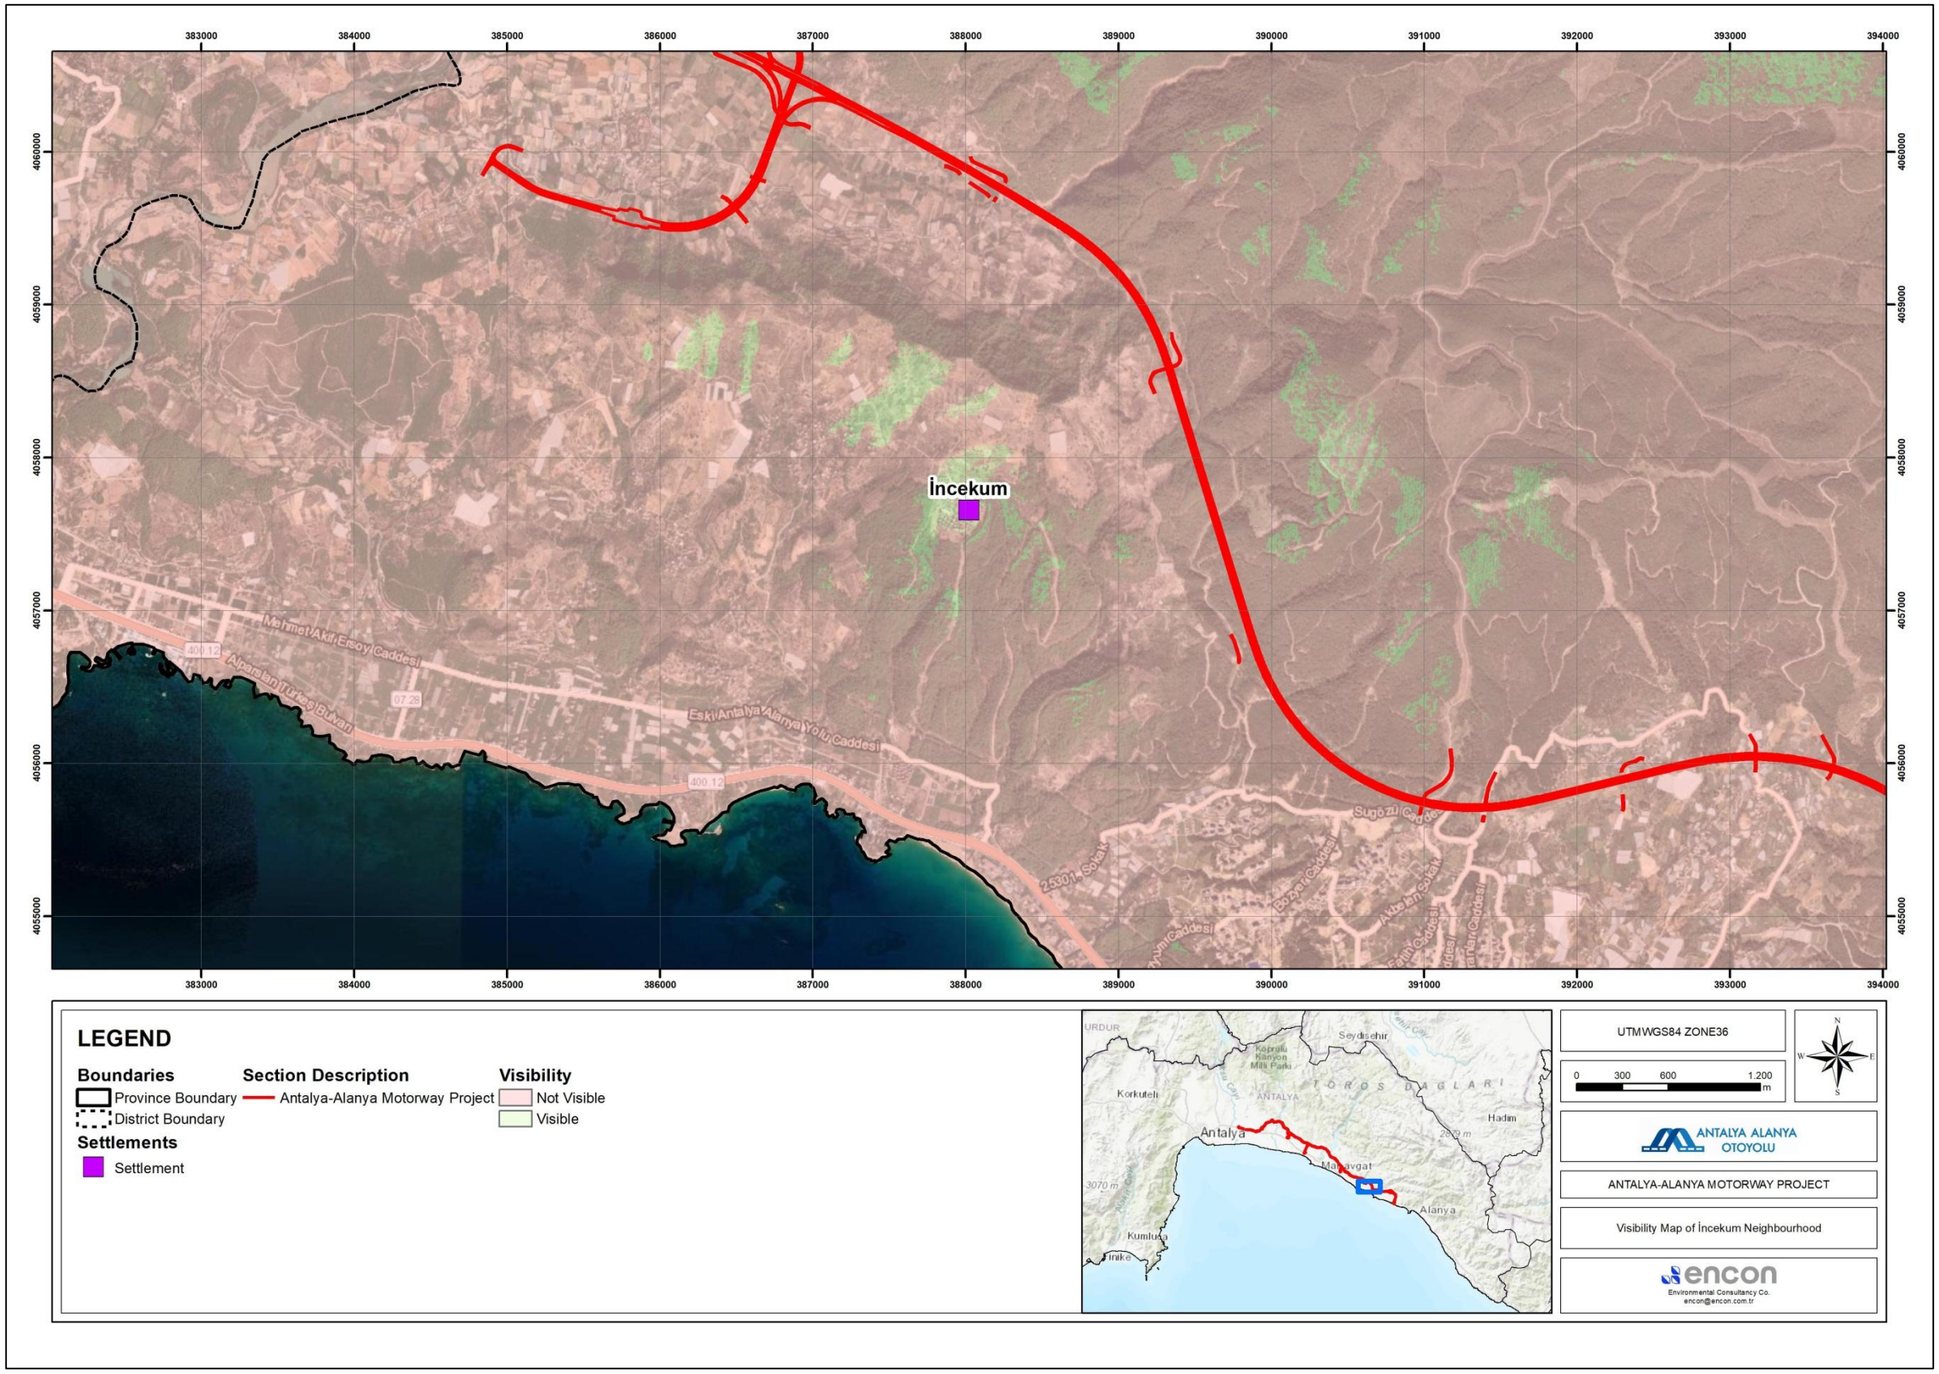

Figure XII.5 Visibility Map of İncekum Neighbourhood for the Project Route (Nonvisible)

XII.2.4. Potential Impacts and Mitigation Measures

Construction of the Motorway and its components will result in the changes in the existing land use. Accordingly, landscape character of these areas will change permanently. Project will have a length of 117.8 km, including the main carriageway and the access roads. The width of the expropriation corridor changes between 100 meters to 450 meters depending on the scale of excavation and fill requirements and footprints of the road structures such as interchanges, service areas, etc. Therefore, landscape in the mentioned area will be affected. In addition, quarries and campsites will have potential impacts on landscape.

Land Preparation and Construction Phases

Potential Impacts

Construction activities of the Project will be completed in 3 years thus the changes in the landscape and visual impacts due to construction components such as campsites, large earthmoving activities, construction machinery, etc. will be relatively temporary in nature. However, there will be disruption to the local landscapes in the immediate vicinity of the Motorway route. These will mainly result from:

- Campsites
- Large earthmoving activities
- Construction machinery
- Quarry sites
- Construction works of bridge and viaduct
- Temporary fences around construction areas
- High visibility cones or concrete blocks
- Construction of toll plazas and associated buildings
- Construction of parking areas and the service areas

Mitigation Measures to be taken

Main aims of the mitigation measures regarding landscape and visual impacts are keeping the changes as small as possible and limiting the visibility of the adverse changes while ensuring the design and construction of the project in a manner that the project melts into the landscape. In this regard, protecting existing landscape features such as shrubs, trees, and natural topography and avoiding unnecessary earthmoving activities are the main components of mitigation strategy. During the period of construction, following measures will be taken to reduce impacts of the works on the landscape and on viewers:

- To protect the existing vegetation and maintain the landscape's integrity, temporary protective fencing will be installed before any work begins on site. This will help preserve as much of the vegetation as possible and retain the natural visual screening.
- Working areas will be kept as small as practicable. Visual barriers will be implemented if the area is subjected to high visual impacts.
- The construction sites will be kept tidy and workers will have necessary knowledge/training about the issue.
- Temporary fencing will be implemented to obstruct visibility from the outside to the intense construction activity areas.
- Planting will be implemented to restore or compensate for lost habitats.

- Planting mixes will be selected using native species and planting will be set out to establish new and enhance existing native habitats. The use of native species throughout the area is important in order that the Motorway planting will, over time, become almost indistinguishable from the vegetation naturally occurring in the surrounding area.

Operation Phase

Potential Impacts

Operational phase impact sources will be the Motorway itself and the associated structures for operation of the Motorway. The impacts during the early operation phase of the Project will be the highest in terms of visual impacts since implementation of the mitigation measures, such as planting of trees, will be in the early stages. In the continuing years of operation the visual impacts would be further decreased. The components of the Project that would cause impacts can be summarized as follows:

- Motorway alignment
- Interchanges
- Bridges
- Viaducts, culverts
- Service areas and parking areas
- Toll plazas
- Lighting structures around interchanges, service areas and toll plazas

Mitigation Measures to be taken

General Directorate of Highways (KGM) has technical specifications for landscaping works and a motorway maintenance handbook. These specifications cover project design, implementation and operation/maintenance phases. Therefore, all mitigation measures about landscaping have been provided in the technical attachments of the contract, and Project Sponsor is responsible to implement and keep these measures. According to KGM handbook, side slopes that are wider than three meters should be afforested. In case side slope is narrower than three meters, side slope should be planted with groundcover species, shrub and tree clubmoss. Similarly, central reserves that are wider than three meters should be planted with shrub and tree species.

In this regard, landscaping activities will be conducted along the Project Route in order to minimize the potential impacts of the Project on the natural environment, ensure slope stability, form a barrier against noise and gaseous emissions, avoid monotonous driving conditions and develop aesthetic appearance. In the scope of the activities, existing local soil conditions, natural vegetative structure, existing plant species on the cultivation areas and irrigation/watering requirements of the potential species to be planted are going to be considered. The following can be outlined as the major mitigation measures for the Project:

- Planting will be implemented to reconnect hedgerows or areas of planting formerly severed as a result of the maintenance works in order to maintain wildlife corridors.
- Landscape design will be coherent with regional landscape identity to the extent possible.
- Planting treatments will be designed to visually screen road structures and earthworks from nearby housing and settlements.

- Planting treatments will be planned according to key views and vistas which will reinforce local identity and minimize driver monotony.

Summary of Assessments and Residual Impacts

Temporary impacts of the construction phase can be mitigated to acceptable levels by means of proper rehabilitation of the construction sites. Therefore, residual landscape and visual impacts would be mostly low. Visual changes due to the Motorway and permanent structures will cause a long-term impact on the landscape. However, since the motorway projects are linear projects, visual impacts will occur in a narrow but long corridor (200 meters of each side of the Motorway Axis). Thus, residual impact for the operation is evaluated as medium.

Especially at the areas where rural landscape character is observed, the landscape character will change considerably at certain sections. Therefore, residual impact at these sections is considered as medium for construction phase. However, once landscape works are completed in operation phase (in 5-15 years), residual impact at these areas is expected to be low.

Summary of the landscape, visual environment and protected areas assessments is presented in Table XII.16.

Table XII.16 Summary of the Landscape, Visual Environment and Protected Areas Assessment

Affected Ecosystem Component		Definition of Potential Impact	Type of Impact	Impact Magnitude						Sensitivity/ Value of Resource /Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
				Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
Land Preparation and Construction Phases													
Landscape*		Change of existing landscape	Adverse	Local	Medium	Medium	Irreversible	Continuous	Major (A)	Medium (2) to Low (1)	High (A2) to Medium (A1)	To protect the existing vegetation and maintain the landscape's integrity, temporary protective fencing will be installed before any work begins on site. This will help preserve as much of the vegetation as possible and retain the natural visual screening. These activities will be conducted under the supervision of the local imam and the village head (muhtar). In addition, for known graves, waivers of consent will be obtained from the family members.	Low
	HRM-32		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	Excavation works and permitting processes are ongoing.	Low
	HRM-40		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	Design Processes are ongoing	Low

Affected Ecosystem Component		Definition of Potential Impact	Type of Impact	Impact Magnitude						Sensitivity/ Value of Resource /Receptor	Impact Significance (Before Mitigation)	Measures to be Taken	Significance of Residual Impacts
				Geographic Extent	Duration	Magnitude	Reversibility	Frequency	Overall Magnitude				
	HRM-42		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	Excavation works and permitting processes are ongoing.	Low
	HRM 31		Adverse	Restricted	Long	Low	Reversible	Intermittent	Moderate (B)	Medium (2)	Medium (B2)	A route change has been completed to avoid potential impacts on cultural heritage sites.	Low
	HRM 3, HRM 6, HRM 9, HRM-11, HRM-16		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	High (3)	High (B3)	During the construction activities, this area needs to be marked and should be prevented from being damaged. It is recommended that the Directorate of the relevant Archaeological Museum should be informed of its existence to carry out on-site field inspections and if needed for registration to ensure its protection. If an on-site inspection will be done the archaeological area in mention could be proposed for being declared either as a 1st or 3rd Degree Archaeological Site by the Museum. The construction works around the area require archaeological on-site monitoring. The notifications of the museum directorate will be followed.	Medium
	HRM-3		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	All necessary permits have been obtained from the Regional Conservation Board, and there are no constraints for proceeding with the construction works.	Low
	HRM-6		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	In the section where a route change could not be implemented, a deliberate narrowing of the project footprint was carried out to prevent damage to the identified wall alignments. This measure was taken specifically to ensure that these features are not impacted by construction activities. Trial pits will be start.	Low
	HRM-9		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	It was evaluated by the Board and was not registered. Board permit has been obtained.	Low
	HRM-11		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	It was evaluated by the Board and was not registered.	Low
	HRM-16		Adverse	Restricted	Long	Medium	Irreversible	Continuous	Moderate (B)	Medium (2)	Medium (B2)	All necessary permits have been obtained from the Regional Conservation Board, and there are no constraints for proceeding with the construction works.	Low

**Sensitivities of these ecosystem components are designated with considering their existence in overall Motorway Route*

XIII. CULTURAL HERITAGE

This chapter identifies the current status of archaeological and immovable cultural heritage that may be relevant to Antalya-Alanya Motorway Project and defines potential impacts of the Project activities on the cultural heritage located within the Project's area of influence, including tangible forms of cultural heritage, unique natural features or tangible objects that embody cultural values, and intangible forms of culture.

To supplement the cultural heritage assessments presented in this Chapter, a Cultural Heritage Management Plan (CHMP) – including a Chance Finds Procedure and a Grave Relocation Procedure – has been prepared as an appendix to this ESIA Report and should be read in conjunction with this Chapter.

The cultural heritage study aims to identify and assess the tangible and intangible cultural heritage on the planned route for the Project and its impact area, describe their expansion limits, assess the potential impact of the construction and operation activities on cultural heritage assets, and offer suggestions for mitigation measures. The cultural heritage baseline and assessment studies were conducted in accordance with the relevant requirements of the national legislation (laws and regulations) and international standards, as outlined in Section XIII.1

The main objectives of the cultural heritage studies conducted as part of the ESIA are as follows:

- To assess the potential for cultural entities and their characteristics in specific locations before construction starts and to develop plans and design strategies for the prevention of construction damage in those areas located on the Project Site,
- To provide data on the identified potential areas to be included in reports for the purposes of proper planning of the construction of the Project (including the Project calendar) to avoid delays in the Project construction activities,
- To develop strategies following the legal procedures, and to propose changes (if needed) in routing/transposition of associated facilities in areas of high archaeological value. To propose further actions to be taken where re-routing/transposition of associated facilities is not possible,
- To collect and record archaeological data scattered over the construction area through the use of scientific methods described below, and to facilitate the transportation of movable cultural heritage items to the relevant museums,
- To archive, all data gathered on archaeological sites and to prepare identification and registration tags of archaeological assets for being reported to the Ministry of Culture and Tourism of the Republic of Türkiye, and
- To enrich the cultural and archaeological inventory of Türkiye with the attested new archaeological finds and features

The studies on the cultural heritage within the scope of the ESIA process were conducted by the expert group of HERMES Archeology & Environmental and Social Consultancy Company (from now on called Hermes), with field surveys undertaken between 26th of August and 8th of September in 2024 and 14th and 17th of March 2025.

The names of the archaeologists who conducted the study and contributed to the report are presented in below table (see Table XIII-1):

Table XIII-1 Expert Team Table Performing the Study

Name	Title	Duty
Engin ÇOŞAR	Senior Archaeologist	Field Coordinator, Field Studies, Reporting
Ahmet Levent KESKİN	Archaeologist	Field Studies, Reporting
Gözde ERGÜL	Archaeologist	Reporting, Support

As part of the studies, the Antalya Regional Board for the Protection of Cultural Heritage (ARHB) was consulted by the Project, through KGM. Cultural heritage findings were reported by KGM to the Board, site visits were conducted by the ARHB officials as required, and official ARHB decisions were obtained for each site accordingly. **Table XIII-7** presented in **Section XIII.3** of this Chapter *"Cultural Heritage Baseline"*, also summarizes the permitting status of each site based on the decisions of the ARHB. This table will serve as a permitting tracker throughout the Project implementation phase.

The ARHB decisions – including a tracker indicating the permitting status of each site – are also presented in Appendix 3 of the Cultural Heritage Management Plan (CHMP).

XIII.1. Regulatory Requirements and Applicable International Standards

XIII.1.1. National Legislation

XIII.1.1.1. Tangible Cultural Heritage

In Türkiye, the movable and immovable cultural and natural assets are under protection and conservation with the "Law on Preservation of Cultural and Natural Assets", 2863 that was amended by law numbered 3386 (Date of Acceptance: 21.07.1983, published in the Official Newspaper issue 18113 with date 23.07.1983). According to the Law, essential assets which are identified as cultural and natural heritage under legal protection are identified as follows:

- Natural and immovable cultural assets belonging to the 19th century and before,
- Any immovable cultural asset constructed after the end of the 19th century but categorized as "a significant asset which requires preservation" by the Ministry of Culture and Tourism,
- Immovable cultural assets located within the Protection Sites (in the Law, Protection Sites are defined as ancient sites and city ruins that reflect the main social, economic or architectural characteristics of their era. Protection Sites may also be locations where fundamental historical events took place or areas containing considerable natural or cultural assets with natural or cultural features requiring preservation),
- Structures, buildings or places that have witnessed significant historical events during the Turkish Independence War or the foundation of the Turkish Republic, regardless of time and registration; and
- All dwellings and buildings used by Mustafa Kemal ATATÜRK without considering their time of construction or registration.

Within the scope of this Law, the Ministry of Culture and Tourism and its local branches (Boards for Preservation of Cultural and Natural Assets, Museums) are responsible for taking decisions at a national level and providing necessary legal actions to protect cultural and natural assets listed above. At the local level, Regional Boards for Preservation of Cultural and Natural Assets are responsible for registering and classifying the cultural and natural heritage, inspecting and making decisions regarding

land use and construction works related to motorway projects which can affect these assets. Declaration of site protection, covering discovered cultural heritage located in their area of authorization, is also under the responsibility of the Regional Boards, whose decisions can directly affect the Project, too.

According to the Law on Preservation of Cultural and Natural Assets numbered 2863, all-natural and cultural assets meeting conditions for legal preservation are the property of the State. Therefore, regional boards have the power and the authority to ensure the legal protection and conservation of relevant sites and to approve or reject all activities that have the potential for negative impacts on these sites, such as construction, destruction, road cuts, and excavation. Currently, the Antalya Regional Board for Preservation of Cultural and Natural Assets is the board responsible for the Project Area.

Apart from the Law on Preservation of Cultural and Natural Assets numbered 2863, some additional regulations do exist governing the procedures for the protection and preservation of cultural and natural assets. First is the Principal Decision of the Ministry of Culture and Tourism of Türkiye named "Protection and Use Conditions of Archaeological Sites" (No. 658, issued 5 November 1999). This decision states that all archaeological sites need to be classified and protected according to their significant features. Three main categories are determined as relevant to archaeological sites:

- 1st Degree Archaeological Sites
- 2nd Degree Archaeological Sites
- 3rd Degree Archaeological Sites.

1st Degree Archaeological Sites: Areas requiring the highest level of protection. They should be preserved except for scientific excavations. The area should be free of any type of building and construction. All kinds of construction, excavation, and modification activities are prohibited. However, for exceptional cases such as the necessity for infrastructure construction, Regional Preservation Boards may permit such activities based on the approval of the relevant museum and the head of the scientific excavation team.

2nd Degree Archaeological Sites: Areas requiring a medium level of protection. They should be preserved based on the conditions of protection and utilization set by the Regional Preservation Boards. Additional construction is prohibited. As for the 1st-degree archaeological sites, for exceptional cases such as the necessity for infrastructure construction, Regional Preservation Boards may permit such activities based on the approval of the relevant museum and the head of the scientific excavation team.

3rd Degree Archaeological Sites: Lowest level protection area. New arrangements can be permitted in these archaeological areas in light of the protection and making use decisions. Construction is permitted based on the decisions of Regional Preservation Boards. Before applying for a construction permit, test pit excavations should be conducted, and the relevant museum should review the outcomes of these excavations and, if present, the head of the scientific excavation team. Reviews should be submitted to Regional Preservation Boards. The Boards may ask for an extension of the areal test pit coverage before taking any decision.

Furthermore, "Implementation Guidelines for Field Surveys, Test Pits and Excavation Works on Cultural and Natural Assets" of the Ministry of Culture and Tourism of Türkiye, with the approval number 94949537-160.99-51264, dated 13/03/2013, defines the procedures for salvage excavations, archaeological test pits, and other studies that might be required.

XIII.1.1.2. Intangible Cultural Heritage

The United Nations Educational, Scientific and Cultural Organization (UNESCO) accepted the "Convention for the Safeguarding of the Intangible Cultural Heritage" in 2003. Türkiye became a party to the UNESCO Convention on Intangible Cultural Heritage in 2006.

According to the Article 2 of the Convention:

The "intangible cultural heritage" means the practices, representations, expressions, knowledge, skills – as well as the instruments, objects, artefacts and cultural spaces associated therewith – that communities, groups and, in some cases, individuals recognize as part of their cultural heritage. This intangible cultural heritage, transmitted from generation to generation, is constantly recreated by communities and groups in response to their environment, their interaction with nature and their history, and provides them with a sense of identity and continuity, thus promoting respect for cultural diversity and human creativity.

For the purposes of this Convention, consideration will be given solely to such intangible cultural heritage as is compatible with existing international human rights instruments, as well as with the requirements of mutual respect among communities, groups and individuals, and of sustainable development.

Buildings, historic places, monuments, and artefacts are cultural property. Intangible heritage consists of nonphysical intellectual wealth, such as folklore, customs, beliefs, traditions, knowledge, and language. In 2001, UNESCO surveyed States and NGOs to try to agree on a definition, and the Convention for the Safeguarding of the Intangible Cultural Heritage was drafted in 2003 for its protection and promotion. Türkiye became a party to the Convention in 2006.

Within the Convention, the "intangible cultural heritage" is manifested inter alia in the following domains:

- oral traditions and expressions, including language as a vehicle of the intangible cultural heritage (myths, epics, legends, folk tales, riddles, poems, lullabies, etc.),
- performing arts (traditional theatre, puppets, folk dance, folk music etc.),
- social practices, rituals and festive events (birth, circumcision, farewells to military, weddings, anniversaries, Hıdrellez, The Navruz, Sema, Semah etc.),
- knowledge and practices concerning nature and the universe (folk meteorology, traditional cuisines, etc.),
- traditional craftsmanship (pottery, wood carving, telkari, paper marbling etc),

XIII.1.2. Applicable International Standards

The international standards applicable to the Project's cultural heritage assessment and management processes include the following:

- International Finance Corporation (IFC) Performance Standard 8 (PS 8) (2012)
- Asian Infrastructure Investment Bank (AIIB) Environmental and Social Framework (Approved February 2016 (Amended February 2019, May 2021, November 2022, and June 26, 2024), Environmental and Social Standard 1 on Environmental and Social Assessment and Management – Requirements on Cultural Resources
- Equator Principles (EP) 4 (2020)

The following international guidelines have also been taken into consideration as part of the study:

- International Finance Corporation - IFC, Performance Standard 8.
- European Bank for Reconstruction and Development - EBRD, Environmental and Social Policy, PR8, Cultural Heritage.
- UK Department for Transport, Design Manual for Roads and Bridges Part 2 HA 208/07 Cultural Heritage.
- Guidance on Heritage Impact Assessments for Cultural World Heritage Properties, International Council on Monuments and Sites (ICOMOS) January 2011.

- Asian Infrastructure Investment Bank (AIIB), Environmental and Social Framework (June 2024).

According to IFC PS 8, requirements related to replicable and non-replicable cultural heritage are as follows:

*Removal of **Replicable** Cultural Heritage:*

11. Where the client has encountered tangible cultural heritage that is replicable and not critical, the client will apply mitigation measures that favor avoidance. Where avoidance is not feasible, the client will apply a mitigation hierarchy as follows:

- Minimize adverse impacts and implement restoration measures, in situ, that ensure maintenance of the value and functionality of the cultural heritage, including maintaining or restoring any ecosystem processes4 needed to support it;
- Where restoration in situ is not possible, restore the functionality of the cultural heritage, in a different location, including the ecosystem processes needed to support it;
- The permanent removal of historical and archeological artifacts and structures is carried out according to the principles of paragraphs 6 and 7 above; and
- Only where minimization of adverse impacts and restoration to ensure maintenance of the value and functionality of the cultural heritage are demonstrably not feasible, and where the Affected Communities are using the tangible cultural heritage for long-standing cultural purposes, compensate for loss of that tangible cultural heritage.

*Removal of **Non-Replicable** Cultural Heritage:*

12. Most cultural heritage is best protected by preservation in its place, since removal is likely to result in irreparable damage or destruction of the cultural heritage. The client will not remove any nonreplicable cultural heritage,5 unless all of the following conditions are met:

- There are no technically or financially feasible alternatives to removal;
- The overall benefits of the project conclusively outweigh the anticipated cultural heritage loss from removal; and
- Any removal of cultural heritage is conducted using the best available technique.

XIII.2. Assessment Methodology and Data Sources

This section outlines the methodology and key data sources used for the identification, evaluation, and protection/management of both tangible and intangible cultural heritage within the Project Area, in line with national legislation and relevant international standards.

The study area for the archaeological and immovable cultural heritage assessments has been identified as the 400 m corridor (200 m from each side of the Motorway axis). The methodology followed in the scope of the studies has consisted of the following four phases.

- Pre-Field Work and Desktop Studies including consultations and official correspondence with the ARHB
- Field Surveys
- Impact Assesment
- Reporting

The archaeological findings that are highly likely to be encountered during a field survey could be listed below[1]:

- Plain settlements,
- Flat ground settlements,
- Hilltop settlements,
- Mounds,
- Chapel,
- Cemeteries (Late Ottoman, Early Republican),
- Monumental Tombs,
- Necropoleis,
- Sanctuaries,
- Modern Cemeteries,
- Lookout Towers,
- Forts,
- Aqueducts,
- Ancient Bridges,
- Ancient roads and culverts,
- Areas of Archaeological Potential, etc.

[1] https://www.oxfordreference.com/display/10.1093/acref/9780199534043.001.0001/acref-9780199534043?btog=chap&hide=true&pageSize=20&skipEditions=true&sort=titlesort&source=%2F10.1093%2Facref%2F9780199534043.001.0001%2Facref-9780199534043
https://dictionary.cambridge.org/dictionary/

The archaeological evaluation method of a determined area is made according to the table below (see Table XIII-2).

Table XIII-2 Pre- Field Work and Desktop Studies

Site	Type of the Surface Material	Intensity Rate of the Surface Material
Registered Sites	Sites that are registered and protected by Law No. 2863.	
Sites in the Process of Registration **(Registration work continues in these areas).**	Sites that are in the process of registration as per Law No. 2863.	
Non-registered Sites **(According to the relevant law, these areas must be reported to the Museum Directorate within 72 hours of their identification).**	Sites that are cultural assets but non-registered	
Non-registered Potential Archaeological Site **(According to the relevant law, these areas must be reported to the Museum Directorate within 72 hours of their identification).**	Ceramic, roof tile, architectural stone block, glass object shards, stone object shards, metal object shards, bone, etc.	Between 1-10 pieces (Low Intensity), Inside of approximately 100 m^2 area
Non-registered Archaeological Site **(According to the relevant law, these areas must be reported to the Museum Directorate within 72 hours of their identification).**	Ceramic, roof tile, architectural stone block, glass object shards, stone object shards, metal object shards, bone, etc.	Between 10-100 pieces (High Intensity) Inside of approximately 100 m^2 area
	Architectural remains, etc.	1 tumulus, 1 wall, 1 cistern etc.
Non-registered Other Sites **(According to the relevant law, these areas must be reported to the Museum Directorate within 72 hours of their identification).**	Sites include the remains of the bridge, bastion, blockhouse, fountain, entrenchment, grave/cemetery, etc.	

XIII.2.1. Pre-Field Work and Desktop Studies

Prior to field work planned as part of the study, scientific publications, documents, archives of Regional Preservation Boards, Museums, and the Ministry of Culture and Tourism were reviewed through desktop studies.

Firstly, data on provinces, districts, and cities/villages within the scope of the Project Site was thoroughly collected. All publications on previous archaeological works conducted in the relevant geographical regions and data on archaeological sites located in the vicinity of the Project Site and impact area were studied.

Resources that were used during the desktop study:

- Academic publications about archaeological sites around the Project Site and its surroundings,
- Historical maps,
- Reports on previous Cultural Heritage Works and Field Survey Results,
- Inventory Archives of the Ministry of Culture and Tourism.

Additionally, all archaeological sites have been defined during this desktop study phase with the help of topographical maps and satellite imagery.

During the desktop studies, the document formats for collecting data were designed as "Impact Assessment Form" and "Archaeological Status Table", for use in future field works. Impact Assessment Forms include all needed data for the GIS database.

As a result of the research conducted on the Ministry of Culture and Tourism website, numbers related to immovable cultural assets in Antalya province were found and listed below (see Table XIII-3).

Table XIII-3 Statistics of Immovable Cultural Assets in Need of Protection in Antalya, End of 2023

IMMOVABLE CULTURAL ASSETS	Amount
	Antalya
Protected Street	4
Monuments	22
Governmental Buildings	62
Cultural Buildings	675
Military Buildings	130
Industrial or Trading Buildings	170
Religious Buildings	201
Cemeteries	263
Examples of Civil Architecture	2130
Remains	368
TOTAL	4025

Source: https://kvmgm.ktb.gov.tr/TR-44799/illere-gore-korunmasi-gerekli-tasinmaz-kultur-varligi-istatistigi.html

Intangible Cultural Heritage

Within the scope of the **intangible cultural heritage** desktop studies, the work initially focused on desk-based research, reviewing academic publications and regional studies. In addition, research was carried out using the inventory system of the Ministry of Culture and Tourism.

Palaeoanthropological and Paleontological Values

The desktop studies also included a review of the **palaeoanthropological and paleontological** potential of the study area based on specialist literature review, using the following data sources:

- Desk-based review: Scientific articles, reports, museum archives, TAY database and GIS-based inventories; regional geology and geomorphology data.
- Remote sensing and GIS: Satellite imagery, DEM/slope analysis; morphometric indicators of karstic voids and cave networks.
- Fieldwork: Ground-truthing walks and micro-collection; archive and literature research.
- Conservation and permitting: Coordination with museums and the Regional Conservation Board.

XIII.2.2. Field Surveys

The main objective of the field activities was the on-site investigation of all archaeological areas and intangible cultural heritage, including the previously identified ones.

In the detailed surface surveys, the route and the areas with associated facilities, such as quarries and camp (accommodation) sites (which constitutes the cultural heritage study area), were inspected in August and September 2024. A 200-meter buffer on both sides of the motorway (resulting in a total

buffer width of 400 meters) has been established for the study. Dates with favourable weather conditions were specifically selected for this fieldwork.

In the sections where the route was revised, on-site investigations were conducted.

During the surveys, extensive field walking was used to identify movable and immovable archaeological and cultural assets along the Project Site. Areas with low or impossible chances of access (rice fields, dense vegetation, high altitude over 2500 m) were surveyed through satellite imagery and 1/25,000 scaled maps. Due to the stormy season, extensive fieldwork and physical examination could not be carried out in some areas. Additionally, those areas were studied using ancient sources and field surveys/excavations previously conducted.

The following activities were carried out within the scope of intensive surveys:

- determination of the ties of the Project Site with the archaeological areas,
- identification of the spatial extension of the archaeological features by observing the surface findings,
- observing the locations where surface findings were concentrated, and
- identification of sections where the Project Site intercepts the concentration areas.

Only archaeological objects visible on the surface were investigated during the field works.

During the site walking, all findings (architectural remains or traces, graves or traces of graves, mounds, tumuli, castle, etc.) were recorded on Field Survey Forms and included in the daily fieldwork reports. The Project Site, including its immediate surroundings, was taken as the center of the field research.

All computational data on the forms were prepared through the preference of one of the UTM ED50 and WGS systems. Furthermore, all computational data (such as kmz/kml) related to discovered areas were also prepared following the field surveys, for further incorporation into impact assessment and reporting.

Intangible Cultural Heritage

For the fieldwork phase, baseline **intangible cultural heritage** elements were also identified in the settlemented located along the project corridor, through one-to-one interviews with local residents — primarily landowners— who are mostly those affected by the Project. The findings of these interviews are presented in Section XIII.3.3.

Palaeoanthropological and Paleontological Values

The determination of palaeoanthropological and paleontological potential was carried out through a combination of desk-based analysis, specialist literature review, and field verification integrated into the overall cultural heritage survey. The methodology followed the principles of IFC PS 8, ICOMOS Guidance on Heritage Impact Assessment, and Turkish Law No. 2863 on the Protection of Cultural and Natural Assets.

XIII.2.3. Impact Assesment Methodology

The Project activities may have potential impacts on the sites, which have been identified to be located within the Project construction area or study corridor. The impact of the construction activities on the cultural heritage elements (tangible and intangible) and the degree of importance of these elements were assessed in accordance with the criteria proposed in the “Guidance on Heritage Impact Assessments for Cultural World Heritage Properties,” which is also recommended by the Ministry of Culture and Tourism for cultural heritage impact assessment.

In addition, the relevant requirements of the IFC PS 8 have been taken into consideration. The results of the assessments are summarized in Section XIII.3.

Significance of the impacts on the identified cultural heritages within the Project Route were evaluated according to the "Guidance on Heritage Impact Assessments for Cultural World Heritage ("WH") Properties" published by the International Council on Monuments and Sites (ICOMOS), a unit related to UNESCO.

Accordingly, in determining the significance of cultural heritage impacts, both the value of heritage asset and the scale and severity of change/impact were taken into consideration, by using the impact assessment matrix published by ICOMOS, as presented in **Error! Reference source not found.**. The i mpact matrix was taken from the Cultural Heritage Impact Assessment (CHIA) Guidance published by ICOMOS.

VALUE OF HERITAGE ASSET	SCALE & SEVERITY OF CHANGE/IMPACT				
	No Change	Negligible change	Minor change	Moderate change	Major change
For WH properties Very High – attributes which convey OUV	SIGNIFICANCE OF EFFECT OR OVERALL IMPACT (EITHER ADVERSE OR BENEFICIAL)				
	Neutral	Slight	Moderate/ Large	Large/very Large	Very Large
For other heritage assets or attributes	SIGNIFICANCE OF IMPACT (EITHER ADVERSE OR BENEFICIAL)				
Very High	Neutral	Slight	Moderate/ Large	Large/very Large	Very Large
High	Neutral	Slight	Moderate/ Slight	Moderate/ Large	Large/Very Large
Medium	Neutral	Neutral/Slight	Slight	Moderate	Moderate/ Large
Low	Neutral	Neutral/Slight	Neutral/Slight	Slight	Slight / Moderate
Negligible	Neutral	Neutral	Neutral/Slight	Neutral/Slight	Slight

Figure XIII-1 Impact Matrix defined by ICOMOS Guideline, 2011

Determination of the value of the heritage asset

For the determination of the value of the heritage asset in accordance with ICOMOS guidance, the criteria outlined in **Error! Reference source not found.** was used. This approach incorporates the legal r egistration status of the sites (based on ARHB decisions), replicability characteristics (according to IFC PS8 and based on professional evaluations of the experts), and visibility status (based on experts' site observations).

Table XIII-4 Criteria for Value of the Heritage Assets

Description of the Criteria	[2]Value of Heritage Asset according to ICOMOS Impact Matrix	Law No. 2863 (Protection of Cultural and Natural Assets)	Replicability/ Non-replicability according to IFC PS 8 definitions	Visibility according to the Experts' Site Observations
-Assets with little or no surviving archaeological interest.	Negligible	Non-registered	Replicable	Invisible
-Designated or undesignated assets of local importance. -Assets compromised by poor preservation and/or poor survival of contextual associations -Assets of limited value, but with potential to contribute to local research objectives.	Low	Non-registered	Replicable	Partially Visible
-Designated or undesignated assets that can contribute significantly to regional research objectives.	Medium	3rd Degree Archaeological Area	Replicable / Non-replicable*	Partially Visible
-Nationally-designated Archaeological Monuments protected by the State Party's laws -Undesignated sites of the quality and importance to be designated. -Assets that can contribute significantly to acknowledged national research objectives.	High	1st and 2nd Degree Archaeological Areas	Replicable / Non-replicable*	Fully Visible
-Sites of acknowledged international importance inscribed as WH property. -Individual attributes that convey OUV of the WH property. -Assets that can contribute significantly to acknowledged international research objectives.	Very High	UNESCO	Critical Cultural Heritage / Non-replicable	-

Source: ICOMOS Guidance, 2011.

** Sites with national designation (1st and 2nd Degree) may also meet the IFC Performance Standard 8 'non-replicable' criteria. This classification informs the determination of impact significance in subsequent assessments (see Table XIII-8).*

Regarding the classification of each cultural heritage assets as "replicable" or "non-replicable / critical cultural heritage" according to IFC PS8 and the IFC–EBRD Good Practice Handbook: Cultural Heritage (2018), as well as guidance provided by ICOMOS, three key evaluation axes were taken into consideration, as outlined below.

1. Uniqueness and Irreplaceability

- Evaluate whether the cultural heritage is unique in the period or culture it represents and whether comparable examples exist elsewhere.
- Assets with this characteristic are typically classified as non-replicable / critical cultural heritage.

2. Replicability / Portability

- Determine whether, after comprehensive documentation, the cultural heritage can be relocated or reconstructed elsewhere while maintaining its heritage value.
- Assets that are technically portable or can be reconstructed, and that are not unique, are generally considered replicable.

3. Legal Protection and Community Significance

[2] As discussed in Section XIII.3, none of the cultural heritage assets identified within the cultural heritage study area, are in the status of "world heritage". Therefore, for the determination of the value of heritage asset according to the impact matrix of ICOMOS, the categories given for "other heritage assets or attributes" was used.

- Assess whether the asset is formally registered under national legislation and/or carries long-standing spiritual or ritual importance for local communities.
- The presence of this criterion may result in the asset being treated as critical cultural heritage or, at a minimum, requiring stronger protection as “other heritage.”

These three evaluation criteria were applied collectively to determine the replicability status of each cultural heritage asset within the Project area, as summarized below:

- Uniqueness combined with non-portability → Non-replicable (Critical Cultural Heritage)
- Portability combined with lack of uniqueness → Replicable
- Presence of legal protection or strong community value → Triggers PS8 requirements for critical or at least stronger protection measures.

Based on this methodology, the **value of each heritage asset** identified by the expert team within the cultural heritage study area has been determined by taking into account its legal registration status and replicability characteristics, and is presented in Section XIII.3 “*Baseline Cultural Heritage*”.

Determination of the Scale and Severity of Change/Impact

The scale and severity of impacts (direct or indirect) or changes are assessed based on impact magnitude based mainly on the distance of the assets to the impact source (e.g. construction corridor), which also incorporates whether impacts are temporary or permanent, reversible or irreversible.
The criteria used for the determination of the magnitude of impacts are outlined in **Error! Reference s ource not found.**. Cumulative effect of separate impacts was also taken into consideration, as relevant

Table XIII-5 Magnitude Criteria Used in the Determination of the Scale and Severity of Impacts

Magnitude	Scale and Severity of Change/Impact
%0-%20	No Change
%20-%40	Negligible Change
%40-%60	Minor Change
%60-%80	Moderate Change
%80-%100	Major Change

Based on this methodology, the **scale and severity of change/impact for each heritage asset** identified by the expert team within the cultural heritage study area has been determined by taking into account their location with respect to the construction corridor and activity sites, as well as temporary or permanent, reversible or irreversible nature of impacts, and is presented in Section XIII.4 “*Potential Impacts*”.

For the assessment of **palaeoanthropological and paleontological impacts**, relevant data collected through desk-based analyses and field surveys were synthesised to produce a risk–sensitivity mapping of the corridor, guiding future field investigations, conservation, and monitoring requirements.

XIII.3. Cultural Heritage Baseline

Baseline conditions along the Motorway route and its vicinity have been characterized based on literature data and the findings of the field surveys conducted by the experts of a third party cultural heritage consultancy company commissioned by the Project.

The Province of Antalya, where the Project Site is located and field surveys were made, is among the regions with high archaeological risk zones in Türkiye. Antalya has been continuously inhabited and favored as a settlement from ancient times to the present due to several factors: its strategic location at the starting point of routes leading into the interior of Anatolia, its coastal position along key trade routes, its favorable climate, and the availability of agricultural products grown year-round, which can be transported to numerous destinations. Various cultures have dominated the region from ancient times to the present day, and life in the region has persisted for generations. All these had triggered continuous habituation within the region since antiquity. Nowadays, field inspections and registration works are ongoing in the region under the authority of the Ministry of Culture and Tourism staff.

Considering the cultural heritage potential of the area, the cultural heritage baseline was prepared in accordance with the results obtained from the literature review and fieldwork during which many new and previously unknown archaeological areas were discovered. Some archaeological areas from the Project Route whose knowledge of being already registered by the Ministry of Culture and Tourism was shared by the official letter were situated in the regions of Antalya Province.

During the field surveys (covering the Project Route and facilities areas), a total of 60 registered and non-registered archaeological and cultural heritage sites were identified. Among them, archaeological areas that were previously registered, such as the area called "1st-degree archaeological sites", which are within the borders of the Antalya Provinces, were assessed.

Statistics of archaeological findings according to their periods and types are presented in the figures below (see Figure XIII.2 and Figure XIII.3).

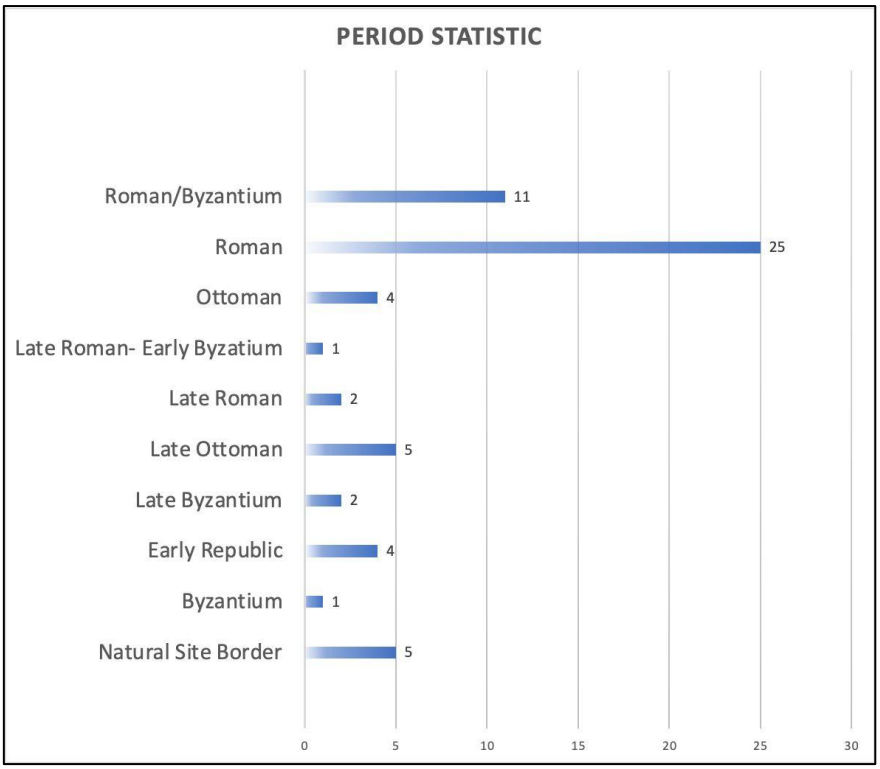

Figure XIII.2 Statistic of Historical Findings

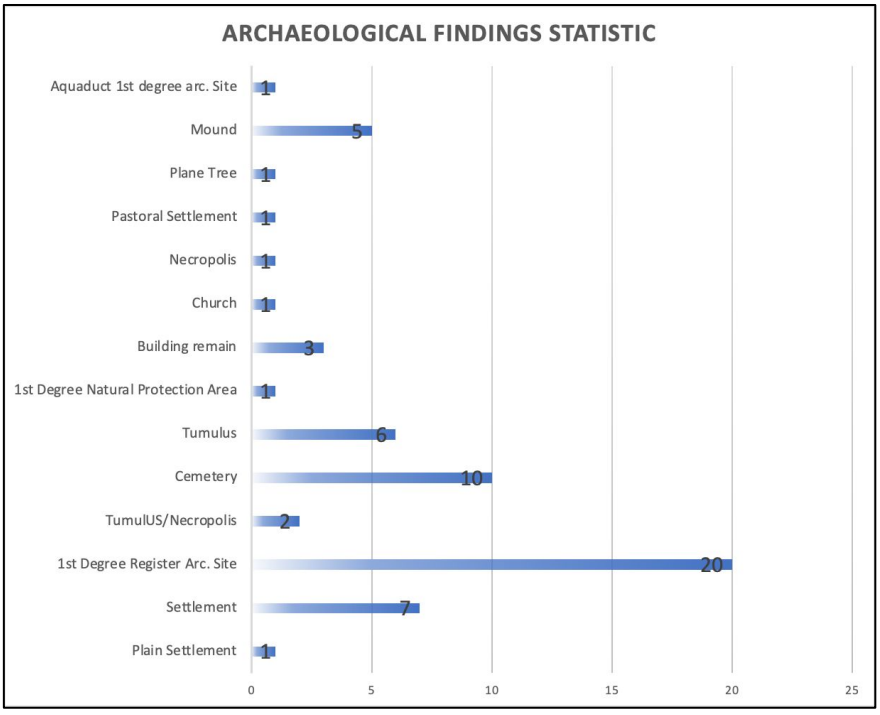

Figure XIII.3 Statistic of Archaeological Findings[3]

[3] The information related to the aquaduct can be accessed from the official website of the Ministry of Culture and Tourism.

XIII.3.1. Historical Geography of the Region

Antalya, known in antiquity as Attaleia, meaning "Land of Attalos", was founded by Attalos II. In antiquity, the surrounding region of the city was referred to as Pamphylia, meaning "very fertile", while the western part of the area was known as Lycia. Beginning in the 8th century BC, migrants from the western shores of the Aegean Sea established cities such as Aspendos and Side in this region. In the mid-2nd century BC, King Attalos II of Pergamon attempted to besiege Side, located approximately 75 km east of modern-day Antalya. Failing to capture the city, he proceeded to the area where the present city of Antalya stands and founded a new settlement. After the Kingdom of Pergamon fell in 133 BC, the city remained independent for a period before being taken over by pirates. By 67 BC, Attaleia had become a naval base for Pompeius in his campaigns against piracy. Emperor Hadrian's visit notably influenced the city's development in 130 AD, during which significant investments were made. Under Byzantine rule, Attaleia became a bishopric centre and experienced further growth following its conquest by the Turks. Due to the modern city being built atop the ancient settlement, few remnants from antiquity are visible today. Among the surviving ruins is part of the harbour breakwater, believed to be from the old harbour, along with the surrounding walls. One of the most well-preserved and prominent ancient structures is Hadrian's Gate, which has been restored and remains an important historical monument in Antalya. Over time, some people called the city Atalia, then Adalya. Antalya comes from this name.

Archaeological excavations indicate that human habitation in Antalya and its surrounding areas dates back approximately 40,000 years. Since 2000 BC, the region has been governed by various city-states and empires, including the Hittites, Pamphylia, Lycia, Cilicia, and Persia. It later came under the control of Alexander the Great and his successors, such as Antigonus, the Ptolemies, the Seleucids, and the Kingdom of Pergamon. Subsequently, the Roman Republic and later the Roman Empire ruled both the city of Antalya and the wider region.

While the Eastern Roman Empire controlled the region, also known as the Byzantine Empire, it was annexed to Turkish territory by the Seljuks in 1207. During the period of the Anatolian Principalities, it fell under the rule of the Hamitoğulları, a branch of the Teke Tribe. The Teke Turkmens, one of the largest tribes in terms of population in modern Turkmenistan, began migrating to this area in the 11th century. The region, known as the Lakes Region, today—encompassing parts of northern Antalya, Isparta, and Burdur—is also referred to as the Teke region. During the Ottoman period, the center of the Teke Sanjak, affiliated with the Anatolian province, was located in what is now the provincial center of Antalya. At that time, it was referred to as the Teke Sanjak. The current name of the province is a slightly altered form of its ancient name, which was adopted during the Republican period.

The famous Ottoman traveler Evliya Çelebi visited Antalya in the second half of the 17th century and provided detailed observations of the city. He noted that there were four neighborhoods and around three thousand houses within the castle, while twenty-four neighborhoods existed outside its walls. According to Çelebi, the city's bazaar was also located outside the castle, highlighting the vibrancy of trade in the area. He remarked on the harbor, stating it was large enough to accommodate 200 ships, indicating the city's significance as a maritime hub. Antalya was the center of the Teke Sanjak during his time, which was administratively connected to Konya. In the final years of the Ottoman Empire, Antalya was elevated to the status of an independent Sanjak, reflecting its growing importance within the region.

XIII.3.2. Tangible Cultural Heritage Baseline

Archaeological sites within the cultural heritage study area were identified as a result of the desktop studies and field walkover surveys, conducted by HERMES with the help of the Project site senior archaeologist.

Table XIII-6 lists the archaeological and cultural heritage sites identified within the cultural heritage study area, including information on the type, period, location, distance, description, registration status, current status, replicability (replicable / non-replicable), and the sensitivity level of each resource. Each site has been designated with a unique heritage resource (HRM) code. The summary provided within the table constitutes a clear reference for the subsequent impact assessment and mitigation planning.

It is important to note that **none** of the cultural heritage sites identified within the cultural heritage study area is in the status of "world heritage".

Detailed description of each site and photographic documentation is further provided below.

A satellite image showing the Project Site and the sites identified within the cultural heritage study area is presented in **Error! Reference source not found.**.

The findings relevant to these sites identified as part of Project's cultural heritage studies have been reported to the Antalya Regional Board for the Protection of Cultural Heritage. The ARHB are presented in Appendix 3 of the CHMP.

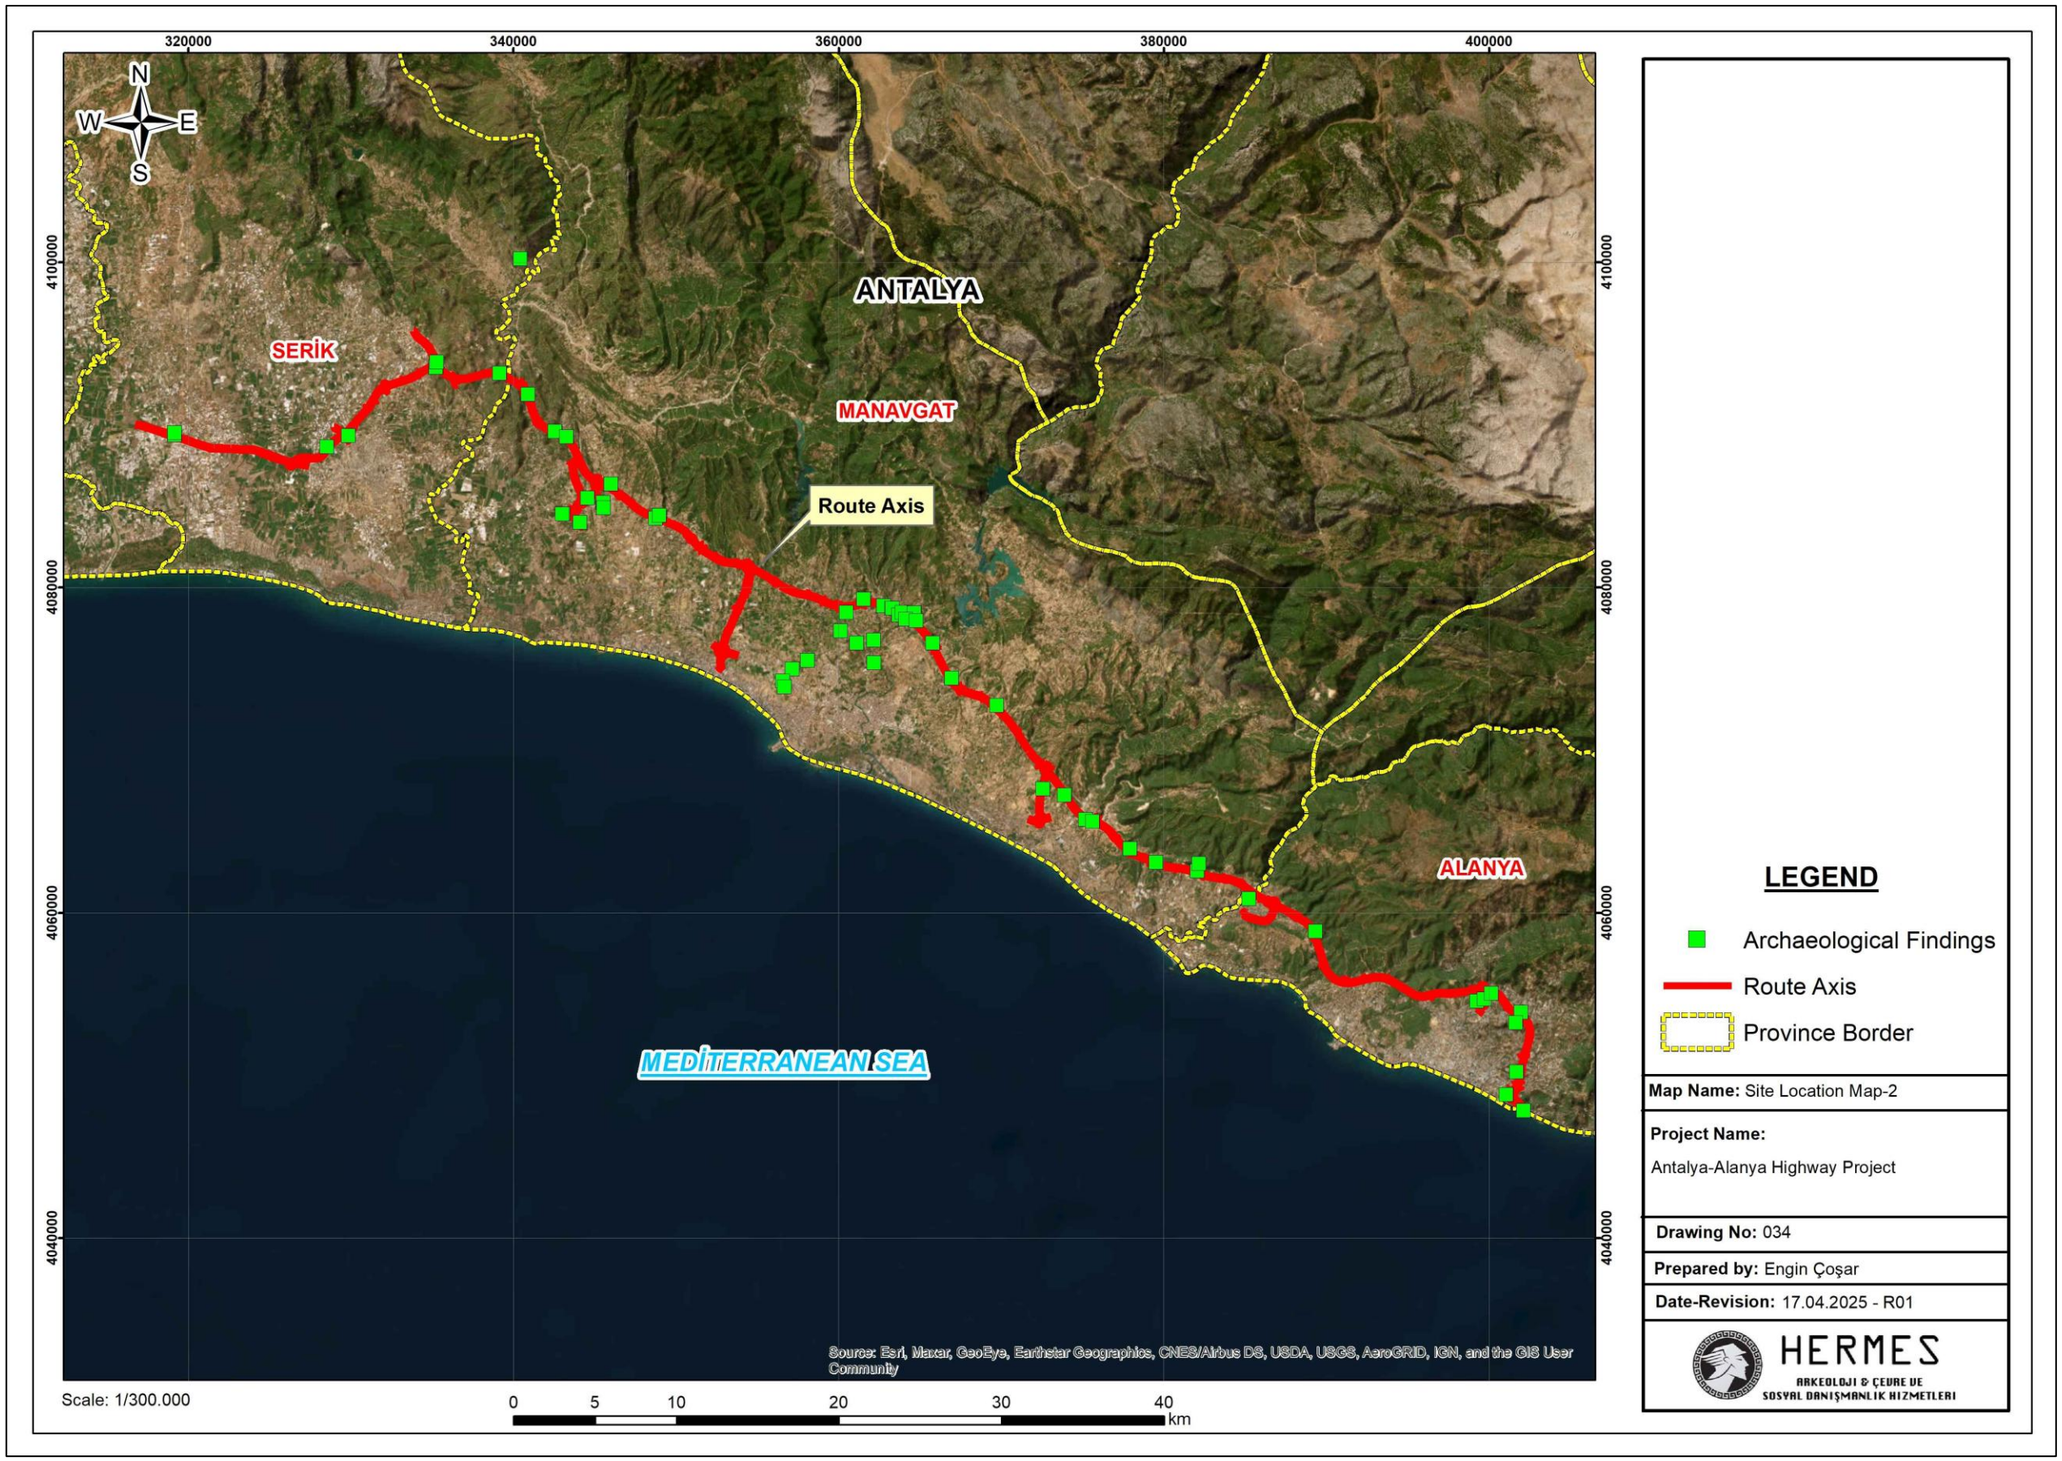

Figure XIII-4 Satellite Image Showing Project Route and Identified Archaeological Assets

Detailed information on each site is provided below.

HRM 1 Cemetery

The cemetery is located at the Yukarıkocayatak junction between Antalya province and Serik district. Upon examining the graves, numerous turban and cap-shaped gravestones were observed. These gravestones, which are similar to those commonly found in the "Beylik" period cemeteries but more frequently in Ottoman period cemeteries, bear Ottoman inscriptions.

Figure XIII.5. General View of the Project Site and Archaeological Findings-1 (HRM 1)

The cemetery is located on the northern side of the Project route and belongs to Kocayatak Village, where it is still actively used. It contains both old and relatively new graves.

Figure XIII.6. General View of the Project Site and Archaeological Findings-2 (HRM 1)

HRM 2 Rural Settlement

It is situated at the Kocayatak junction between Antalya Province and Serik District, north of the HRM 1 cemetery.

The archaeological site is located on a hillside and features a single-phase context. Fragments of daily-use containers were observed at the foot of the hillside.

Figure XIII.7. General View of the Project Site and Archaeological Findings (HRM 2)

Upon examining the pottery, it appears that they can be dated to the later stages of the Byzantine period or the Ottoman period.

HRM 3 Rural Settlement

It is a settlement area situated within the irrigation channels with a partially preserved elevation. The identified ceramics can be dated to the Late Roman and Early Byzantine periods.

Figure XIII.8. General View of the Project Site and Archaeological Findings (HRM 3)

HRM 4 Settlement

During the examinations, tile fragments and pieces of daily use vessels dating back to the 14th-15th centuries were observed on the surface. The area where these findings were made is situated along the edge of a stream, with an elevation rising to the east. It is possible that the ceramics may have been carried down from this elevation to the area near the stream. However, the section where the artifacts were found also presents suitable elevations that could indicate a settlement in this location.

Figure XIII.9. General View of the Project Site and Archaeological Findings (HRM 4)

HRM 5 Cemetery

The site is located within the boundaries of Antalya Province, Serik District, Deniztepesi Neighborhood. Based on information obtained from the query system of the General Directorate of Land Registry and Cadastre, the site is registered as a cemetery (located in block 139, parcel no. 5). Upon investigation, it has been determined that this cemetery dates back to the Early Republican period and is still in use as a modern cemetery.

Figure XIII.10. General View of the Project Site and Archaeological Findings (HRM 5)

Local interviews have confirmed that the cemetery has been in use until recent times, with many of the graves being owned by families of individuals.

HRM 6 Building Remains

There is an archaeological site covered with bushes at a dominant point on the hill, towards the south of the HRM 5 cemetery parcel. Upon examination, it is understood that the site contains wall rows belonging to a square-plan structure, measuring approximately 40 m by 40 m.

Rubble stones, likely belonging to architectural structures, are quite dense on the surface, and wall rows are visible. The walls of the building are 1-2 meters wide and notably thick, suggesting that the structure could have been a terminal garrison settlement. In addition, dense roof tile fragments and a small number of ceramic pieces from daily use containers were detected.

Figure XIII.11. General View of the Project Site and Archaeological Findings (HRM 6)

HRM 7 Tumulus

The site is located on a prominent hill within the Project route corridor, where traces of illegal excavations were detected. Upon examination, rows of walls were observed on the surface. Based on the shape of the archaeological site and the findings, the site is believed to be a tumulus.

Additionally, dense roof tile fragments and scattered ceramic pieces from daily use containers were found around the elevated area.

Figure XIII.12. General View of the Project Site and Archaeological Findings (HRM 7)

HRM 8 Manavgat Natural Site Border

The project plans to cross the Köprü Stream via a viaduct. However, information from the ARHB indicates that there is a protected area along the valley of the Köprü Stream, extending southward and including the ancient city of Aspendos. The Project route intersects with the protected area in several sections, and it is anticipated that intensive construction activities will occur in certain areas related to the Project.

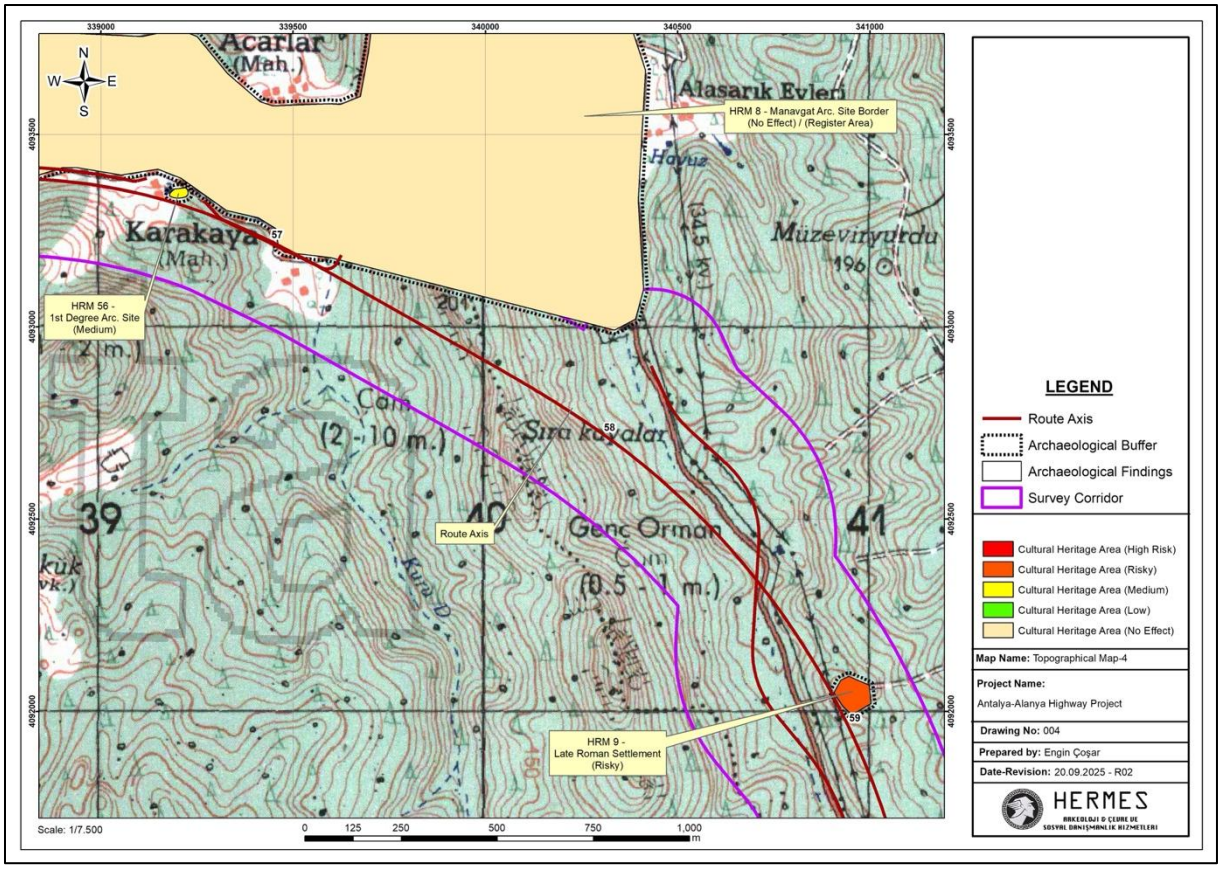

Figure XIII.13. General View of the Project Site and Archaeological Findings (HRM 8)

HRM 9 Late Roman Settlement

The identified structure is believed to be a military and surveillance facility due to its strategic location overlooking a valley and its position on a prominent hill in the area. A dense layer of rubble stone, potentially belonging to architectural remains, is scattered across the surface. Additionally, fragments of roof tiles and ceramics from daily use containers are visible on the surface.

Figure XIII.14. General View of the Project Site and Archaeological Findings (HRM 9)

HRM 10 Settlement

According to the info received from the AHRB, the hill through which the T4 tunnel of the project passes..

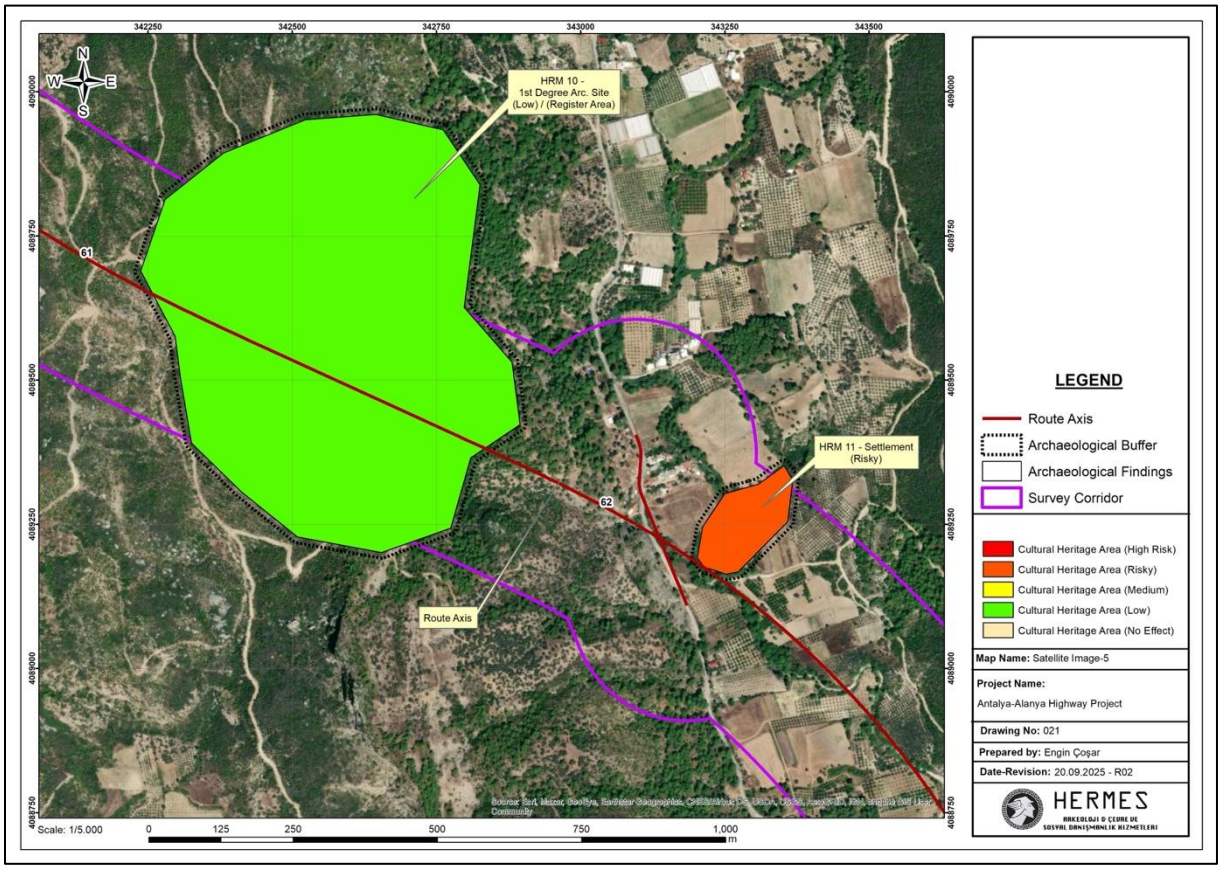

Figure XIII.15. General View of the Project Site and Archaeological Findings (HRM 10)

HRM 11 Archaeological Settlement

The archaeological site is located north of Taşağıl and within the valley extending along a slope by the stream. A significant amount of rubble that may belong to architectural structures is visible on the surface. Additionally, fragments of tiles, fragments from daily use vessels, and terra sigillata sherds have also been observed.

Figure XIII.16. General View of the Project Site and Archaeological Findings (HRM 11)

HRM 12 Necropolis

The necropolis is located within the Project corridor and is situated in a wooded area. High-quality ceramic fragments dating from the 4th to 6th centuries AD are visible on the surface and along the slope sections. Additionally, numerous tile pieces, likely used for covering graves, are present. A significant number of slabs and covering stones that may belong to the graves are also observed in the area.

Figure XIII.17. General View of the Project Site and Archaeological Findings (HRM 12)

HRM 13 Settlement

The settlement is located on a hillside that provides a sheltered view of the surrounding area.

As a result of the route change, the area has been excluded from the project's impact corridor.

Although no architectural traces were observed on the surface, a dense layer of pottery was identified. Additionally, thin-walled, high-quality ceramic fragments dating from the 4th to 6th centuries AD were visible on the surface.

Figure XIII.18. General View of the Project Site and Archaeological Findings (HRM 13)

HRM 14 Cemetery

The site is the Hocalar Village cemetery and covers a substantial area.

As a result of the route change, the area has been excluded from the project's impact corridor.

An examination of the graves indicates that they date from the early Republican period to modern times.

Figure XIII.19. General View of the Project Site and Archaeological Findings (HRM 14)

HRM 15 Cemetery

The cemetery is situated along the Antalya-Mersin road and contains graves from early periods. Some of the graves are constructed with well-cut stone blocks, which are believed to have been sourced from another location and reused in this cemetery.

Figure XIII.20. General View of the Project Site and Archaeological Findings (HRM 15)

HRM 16 Tumulus and Necropolis

In the area designated for the construction of the T5 tunnel, a significant presence of dense and high-quality ceramics was observed on the surface of a hill. Based on the ceramic and glass findings, the archaeological site can be dated to the 4th-5th centuries AD. Additionally, a substantial amount of tile fragments was also noted in the area.

Based on the findings, the identified archaeological site is believed to be either a tumulus or a necropolis.

Figure XIII.21. General View of the Project Site and Archaeological Findings (HRM 16)

HRM 17 Settlement

A diverse range of ceramic pieces is visible on the surface, including amphora fragments and toes, handle pieces from very large amphorae, and fragments from various daily use vessels. Based on these findings, the archaeological site can be dated to the Late Roman period.

Figure XIII.22. General View of the Project Site and Archaeological Findings (HRM 17)

HRM 18 Mound

The archaeological site is within the borders of Çukurören neighbourhood.

As a result of the route change, the area has been excluded from the project's impact corridor.

During the examination, intense concentrations of ceramic and tile fragments dating back to the Roman period were observed on the surface. Additionally, numerous rubble stones and illegal excavation pits were identified.

While the registration boundaries only encompass the top of the mound, artifacts have been noted scattered along the slopes too.

Figure XIII.23. General View of the Project Site and Archaeological Findings (HRM 18)

HRM 19 Manavgat Waterfall Protected Area

Manavgat Waterfall is designated as a protectes sensitive area.

As a result of the route change, the area has been excluded from the project's impact corridor.

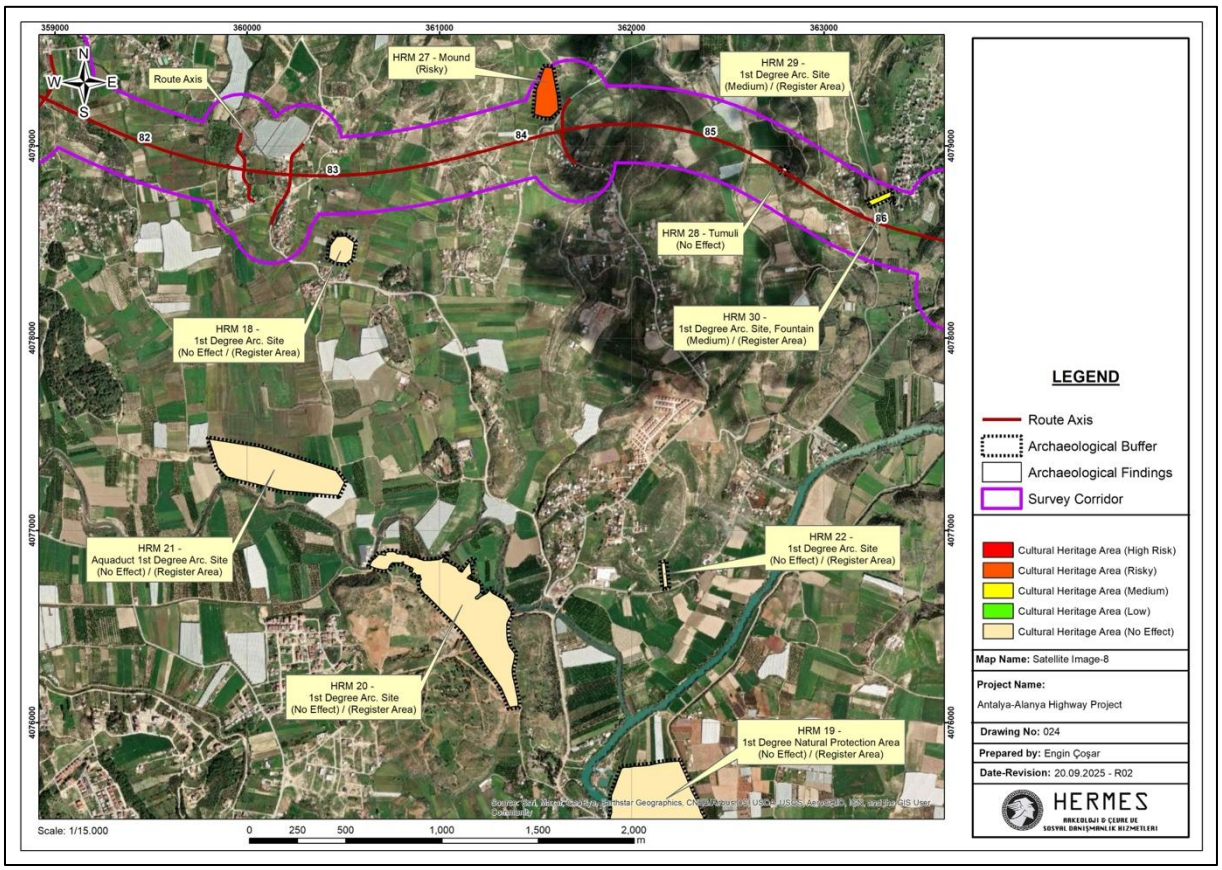

Figure XIII.24. General View of the Project Site and Archaeological Findings (HRM 19)

HRM 20 Aqueduct

Aqueducts were built to transport water to the ancient city of Side. The buttresses of the aqueduct, which still stand today, are constructed from local stones.

As a result of the route change, the area has been excluded from the project's impact corridor.

Figure XIII.25. General View of the Project Site and Archaeological Findings (HRM 20)

HRM 21 Settlement

As a result of the route change, the area has been excluded from the project's impact corridor.

During the survey, a dense ceramic layer was observed on the surface across the entire area. Based on the general appearance of the site, it is believed to be a settlement.

Figure XIII.26. General View of the Project Site and Archaeological Findings (HRM 21)

HRM 22 Aqueduct

When the inventory registration system of the Ministry of Culture and Tourism was checked, it was seen that there is indeed an aqueduct in this area that was registered.

As a result of the route change, the area has been excluded from the project's impact corridor.

Figure XIII.27. General View of the Project Site and Archaeological Findings (HRM 22)

HRM 23 Cemetery

This area is the cemetery of Hatipler Village. Examination of the cemetery reveals that the gravestones were crafted from ancient columns. These stones were repurposed from other locations and brought here for secondary use.

As a result of the route change, the area has been excluded from the project's impact corridor.

Figure XIII.28. General View of the Project Site and Archaeological Findings (HRM 23)

HRM 24 Mound

The mound, situated near Hatipler neighborhood.

As a result of the route change, the area has been excluded from the project's impact corridor.

It exhibits a single-phase settlement character. This archaeological site, positioned at a high elevation compared to its surroundings, contains dense ceramic pieces dating to the Late Roman-Early Byzantine Period. However, due to the area being a cultivated field, a comprehensive examination to ascertain the actual extent of the site could not be conducted.

Figure XIII.29. General View of the Project Site and Archaeological Findings (HRM 24)

HRM 25 Tumulus

In the examinations conducted at the archaeological site, which resembles a tumulus due to its artificial elevation, ceramics dating to the Late Roman-Early Byzantine period were encountered.

As a result of the route change, the area has been excluded from the project's impact corridor.

Figure XIII.30. General View of the Project Site and Archaeological Findings (HRM 25)

HRM 26 Hilltop Settlement

A large number of Late Roman ceramic fragments were identified on the surface of the archaeological site, which appears as a mound due to its elevated form.

As a result of the route change, the area has been excluded from the project's impact corridor.

Figure XIII.31. General View of the Project Site and Archaeological Findings (HRM 26)

HRM 27 Settlement

A significant concentration of Roman pottery and tile fragments was observed on the surface and in the cross-sections of the identified archaeological site. Based on the variety of pottery, the site is believed to be a settlement. Fragments of daily use containers and tiles were also identified.

Figure XIII.32. General View of the Project Site and Archaeological Findings (HRM 27)

HRM 28 Tumulus

During the surveys, a hill with scattered amorphous stones was detected on an elevation overlooking the valley. A small number of ceramic remains were also found in the area, suggesting the possibility of a tumulus.

Figure XIII.33. General View of the Project Site and Archaeological Findings (HRM 28)

HRM 29 Aqueduct

The structure is an aqueduct that transported water to the ancient city of Side, reflecting the architectural style of the Roman period. These aqueducts channeled water from distant sources to the city center to supply the city's water needs. The aqueduct is well-preserved.

Figure XIII.34. General View of the Project Site and Archaeological Findings (HRM 29)

HRM 30 Fountain

The structure is a fountain located near the HRM 29.

It is situated within the Project impact corridor and has an active water flow today. The fountain is regularly used by local residents.

Figure XIII.35. General View of the Project Site and Archaeological Findings (HRM 30)

HRM 31 Necropolis

A necropolis area was detected along the side of the Bucakşeyhler Village road. Bone fragments and covering tile fragments were found in the sections examined.

Since the hill is designated as a necropolis, there is a possibility of encountering graves during the construction works.

Figure XIII.36. General View of the Project Site and Archaeological Findings (HRM 31)

HRM 32 Church Remains

The ruins of a building with walls approximately 4 meters high were identified along the Project route. Based on its architecture, constructed from regionally common stones like sandstone and limestone, and the ceramics found in its vicinity, the structure has been dated to the Roman period. No additional architectural elements were observed around the structure, leading to the assumption that it may have been a singular structure. A large number of ceramic and tile fragments were identified surrounding the site.

It has been reported that the structure was registered within a smaller area, but the ceramics were distributed in a wider area.

Figure XIII.37. General View of the Project Site and Archaeological Findings (HRM 32)

HRM 33 Settlement

The identified archaeological site is located outside the Project impact corridor. However, in case of potential route changes or additional studies, the site has been documented for reference, and caution should be exercised in future site selection.

A significant amount of high-quality ceramic fragments, dating back to the Roman period, were observed on the surface. No signs of architectural elements were identified.

.

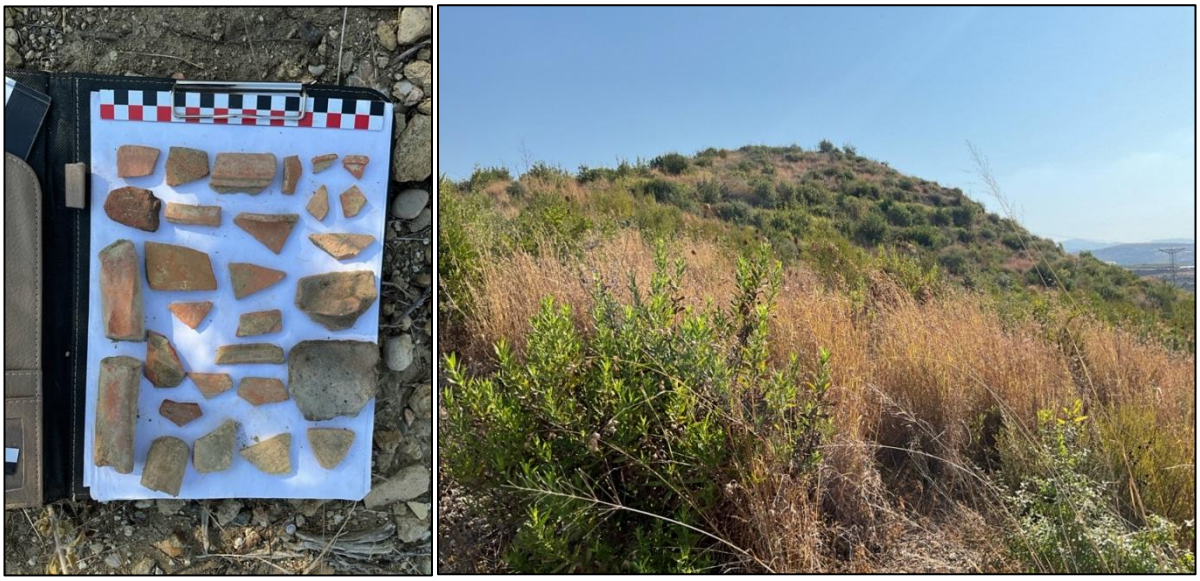

Figure XIII.38. General View of the Project Site and Archaeological Findings (HRM 33)

HRM 34 Cemetery

The cemetery is located on a hill within the Project impact corridor and is believed to contain graves from the Early Republican period. This cemetery, which is used in conjunction with more recent graves, is not expected to be affected by the Project route.

Figure XIII.39. General View of the Project Site and Archaeological Findings (HRM 34)

HRM 35 Building Remains

The site consists of structural walls situated on a slope surrounded by bushes that overlooks the Manavgat River.

Figure XIII.40. General View of the Project Site and Archaeological Findings (HRM 35)

HRM 36 Rural Settlement

Surveys revealed the presence of several ceramic fragments, albeit in limited quantities. The coarse nature of the pottery suggests a date to the Late Ottoman period.

Figure XIII.41. General View of the Project Site and Archaeological Findings (HRM 36)

HRM 37 Settlement

The archaeological site is situated on a hilltop near a stream and falls within the Project impact corridor. The surface is covered with dense rubble stones believed to be remnants of architectural features. Additionally, numerous roof tile fragments and ceramic pieces, including those dating back to the 4th-5th centuries AD and fragments of daily use containers, were identified in the area.

Figure XIII.42. General View of the Project Site and Archaeological Findings (HRM 37)

HRM 38 Settlement

The archaeological site is situated on a hill north of Aksaz Village and contains a significant quantity of ceramics. Based on the findings, the area can be dated between the 3rd and 6th centuries AD.

Alongside high-quality ceramics, glass fragments, handles, pieces of daily use containers, and decorated ceramic rims were discovered. Additionally, rubble stones that may belong to architectural structures were also identified in the vicinity.

Figure XIII.43. General View of the Project Site and Archaeological Findings (HRM 38)

HRM 39 Tumulus

It is an archaeological site situated in a forested area. A significant quantity of ceramic and tile pieces dating back to the Roman Period were discovered. Additionally, a modern water tank is present in the vicinity where the ceramics were found, leading to the belief that a tumulus may have been damaged during the tank's construction.

Figure XIII.44. General View of the Project Site and Archaeological Findings (HRM 39)

HRM 40 Cemetery

The cemetery area is partially intersected by the Project route and is believed to date back to the early Republican period, with gravestones visible on the surface.

Figure XIII.45. General View of the Project Site and Archaeological Findings (HRM 40)

HRM 41 Church or Build Remains

Architectural remains were identified on a hillside alongside the motorway between Seydişehir and Manavgat. Upon examination, it is believed that the remains may indicate the presence of a church-like structure.

During the research, some ceramics were observed on the surface, including roof tiles and pieces from daily use containers. Based on these finds, the site has been dated to the Late Roman to Early Byzantine period.

Figure XIII.46. General View of the Project Site and Archaeological Findings (HRM 41)

HRM 42 Settlement

The settlement is situated on the banks of Çenger Stream within a sheltered location. A significant quantity of pottery and glass dating back to the Late Roman period has been identified on the surface, together with roof tiles and other ceramic fragments from daily use containers. Based on these ceramics, the area has been dated to the Late Roman-Early Byzantine period.

Figure XIII.47. General View of the Project Site and Archaeological Findings (HRM 42)

HRM 43 Cemetery

The cemetery is situated near the village of Kadılar, within a forested area. Both Early Republican period and modern graves have been observed in the vicinity.

Figure XIII.48. General View of the Project Site and Archaeological Findings (HRM 43)

HRM 44 Historical Plane Tree

The plane tree located within the Project impact corridor.

Figure XIII.49. General View of the Project Site and Archaeological Findings (HRM 44)

HRM 45 Cemetery

The site is the Yalçıdibi village cemetery, where a diverse range of graves from the late Ottoman, early Republican, and modern periods has been observed.

Notable features of the cemetery include numerous graves adorned with turbans and those bearing Ottoman inscriptions and various motifs, which highlight the cultural and historical significance of the site.

Figure XIII.50. General View of the Project Site and Archaeological Findings (HRM 45)

HRM 46 Yalçıdibi Waterfall

Literature research indicates that the waterfall in question is likely recognized as a natural preservation area due to its seasonal fluidity.

Figure XIII.51. General View of the Project Site and Archaeological Findings (HRM 46)

HRM 47 Çardaktepe

The Çardaktepe, is situated in the northwest of the Alara District.

In this section, the connection road has been cancelled due to its intersection with an archaeological site.

Drone footage reveals the presence of several structures on the hill, suggesting that these structures extend down to the skirts of the site.

Figure XIII.52. General View of the Project Site and Archaeological Findings (HRM 47)

HRM 48 Building Remains

The architectural remains located on a hillside are believed to belong to a castle or a church-like structure. The walls of the structure are still intact, standing at a height of 3-4 meters.

Figure XIII.53. General View of the Project Site and Archaeological Findings (HRM 48)

HRM 49 Building Remains

The architectural remains located on a hillside are believed to belong to a castle or a church-like structure. The walls of the structure are still intact, standing at a height of 2-3 meters.

Figure XIII.54. General View of the Project Site and Archaeological Findings (HRM 49)

HRM 50 Building Remains

The remains of the building are situated within several gardens and along the boundaries of private property. The walls of the structure are still intact, standing at a height of 5-6 meters.

Figure XIII.55. General View of the Project Site and Archaeological Findings (HRM 50)

HRM 51 Cemetery

The area serves as the Toslak village cemetery, which is still in use today and features graves from the early Republican period.

Figure XIII.56. General View of the Project Site and Archaeological Findings (HRM 51)

HRM 52 Settlement

The archaeological site, located on a hill, is highly a hilltop settlement.

Figure XIII.57. General View of the Project Site and Archaeological Findings (HRM 52)

HRM 53 Build Remains

The archaeological site, located on a hill, is highly a hilltop settlement.

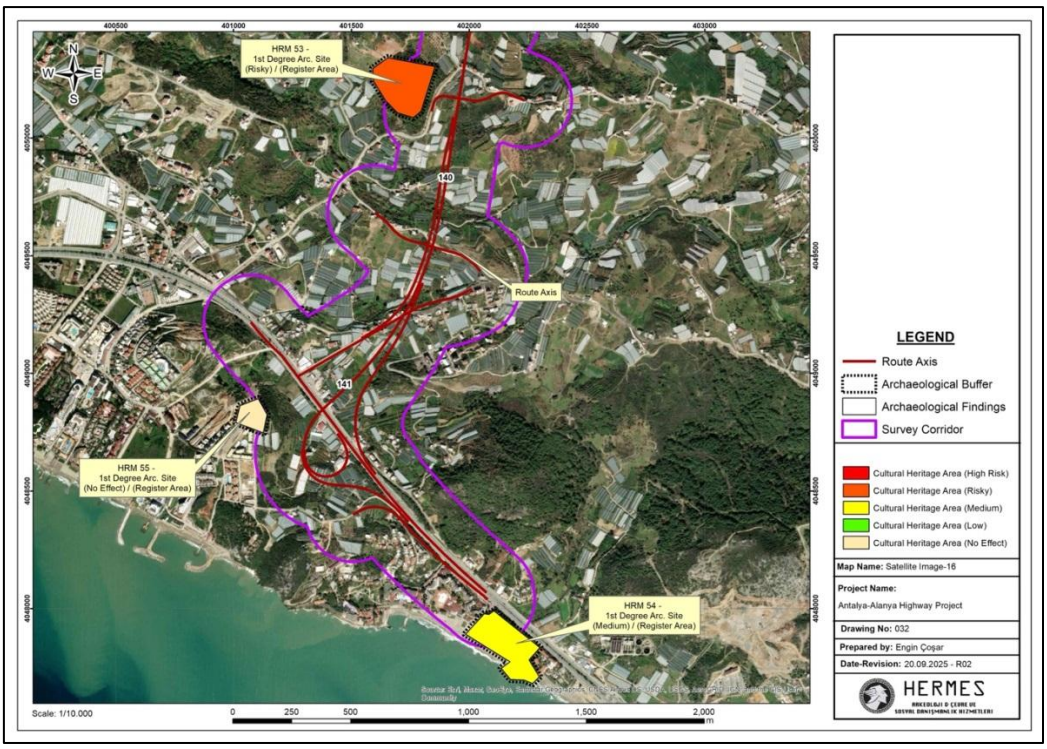

Figure XIII.58. General View of the Project Site and Archaeological Findings (HRM 53)

HRM 54 Build Remains

The site, characterized by the remains of a building along the shore and a green area behind it, is believed to be an ancient port bath or a port-related structure.

Figure XIII.59. General View of the Project Site and Archaeological Findings (HRM 54)

HRM 55 Build Remains

The archaeological remains, located on a slope, highly belong to a castle or a church like structure.

Figure XIII.60. General View of the Project Site and Archaeological Findings (HRM 55)

HRM 56 Building Remains

The project route crosses the Manavgat Stream, this section—where the structure is situated—coincides with an existing asphalt road alignment.

Figure XIII.61. General View of the Project Site and Archaeological Findings (HRM 56)

HRM 57 Settlement

According to the registered site data obtained from the ARHB, it has been determined that the route corridor partially intersects with a designated archaeological site.

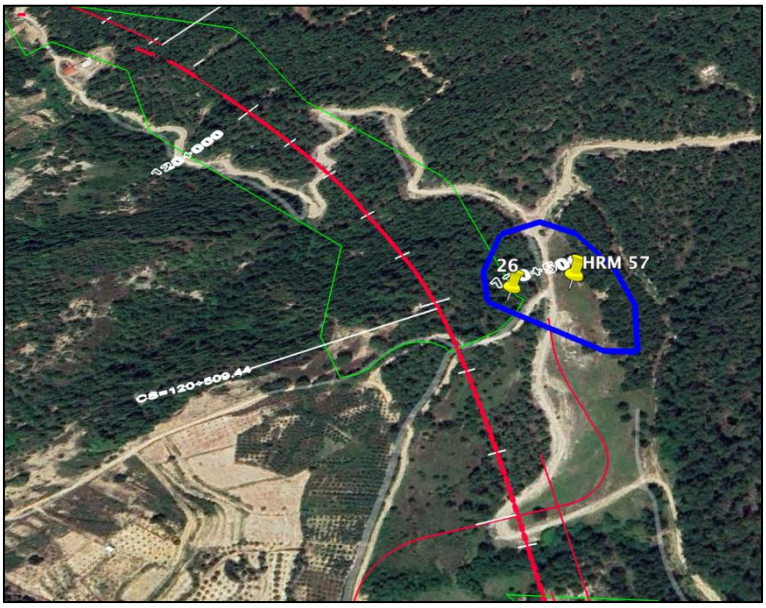

Figure XIII.62. General View of the Project Site and Archaeological Findings (HRM 57)

HRM 58 Settlement

According to the registered site data obtained from the ARHB, it has been determined that the route corridor partially intersects with a designated archaeological site.

Figure XIII.63. General View of the Project Site and Archaeological Findings (HRM 58)

HRM 59 Settlement

According to the registered site data obtained from the ARHB, it has been determined that the project expropriation corridor partially overlaps with an archaeological conservation site. It has also been observed that residential buildings are located within the section where the site lies.

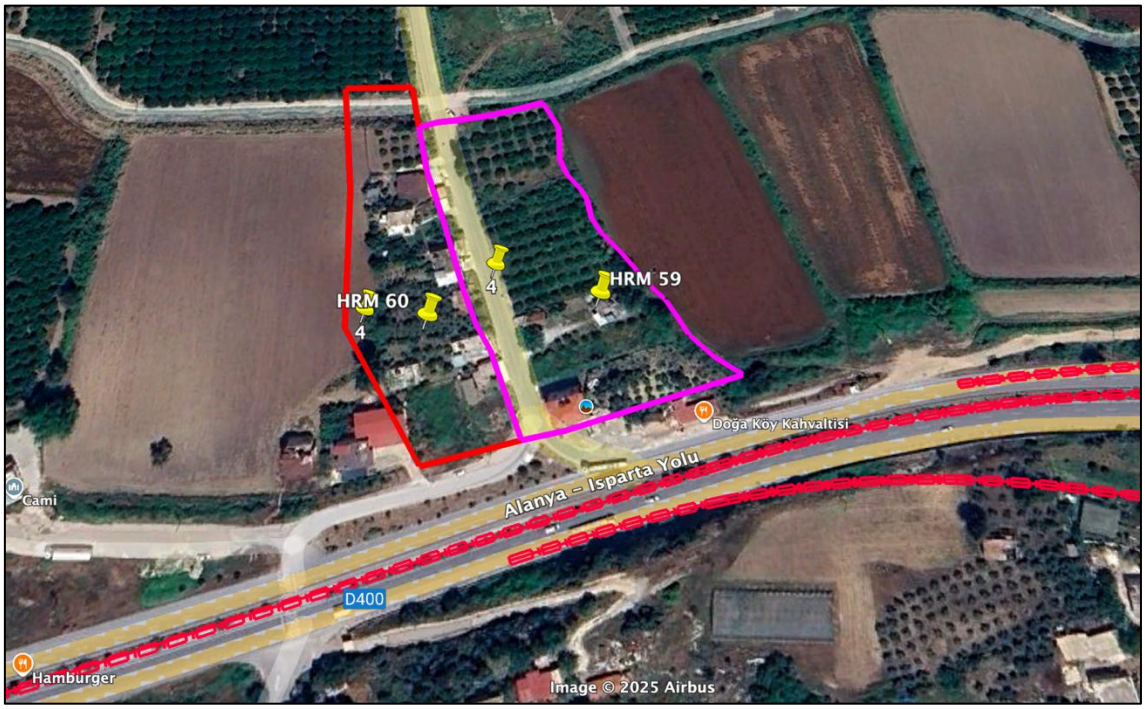

Figure XIII.64. General View of the Project Site and Archaeological Findings (HRM 59)

HRM 60 Settlement or Necropolis

According to the registered site data obtained from the ARHB, it has been determined that the project expropriation corridor partially overlaps with an archaeological conservation site. It has also been observed that residential buildings are located within the section where the site lies.

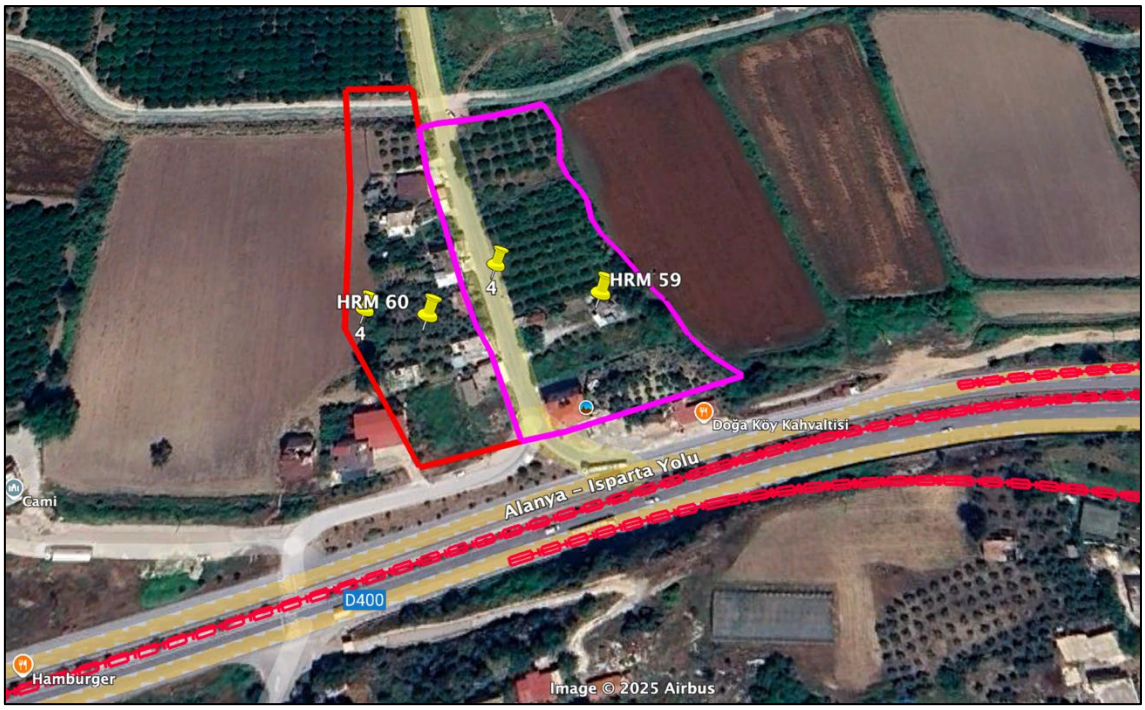

Figure XIII.65. General View of the Project Site and Archaeological Findings (HRM 60)

Table XIII-7 Summary of Identified Tangible Cultural Heritage Assets within the Project Corridor including Permitting Status (presented under Current Status Column)

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
HRM 1	Cemetery	Late Ottoman	South of Kocayatak Antalya/Serik/Yukarıkocayatak	Within	Yes-partially	Late Ottoman-Modern Cemetery Area: The site contains hundreds of graves dating back to the Late Ottoman (18th-19th century) and modern periods Some of the graves have suffered damage due to illegal excavations.	**1st Degree**	**ARHB permitting process is <u>ongoing</u>.** A partial corridor narrowing has been implemented; however, due to the condition of the existing highway and settlement activities in the area, it was decided to carry out a salvage excavation and relocate the graves within the same cemetery. In order to carry out works in these areas, a Technical Justification Report has been submitted to the ARHB. The consultant academics within the ARHB, in line with the relevant legislation and taking into account the opinion of the Museum Directorate, have completed their evaluation and the permits for excavation have been obtained. The finalization of the design is awaited.	Replicable	High
HRM 2	Rural Settlement	Late Byzantium	South of Kocayatak Antalya/Serik/Yukarıkocayatak	138 m	No - does not overlap	Single Phase Rural Settlement: Surface findings include sherds from late-period daily-use vessels. This settlement falls within the project corridor.	**Non-registered**	**ARHB permitting process is <u>complete</u>.** The identified area has been reported to the Museum Directorate, and the procedures at the ARHB have been completed. It was evaluated by the Board and was not registered.	Replicable	Low
HRM 3	Rural Settlement	Late Roman - Early Byzantium	Serik K3 Interchange Access Road Km 8+800 Antalya/Serik/Burmahancı	26 m	Yes-partially	Single-Phase Settlement: Sherds of daily-use vessels from the Late Roman-Early Byzantine period have been identified on the surface. No architectural remains are visible. The site is situated between fields and the canal.	**1st Degree**	**ARHB permitting process is <u>complete</u>.** The identified area has been reported to the Museum Directorate, and the procedures at the ARHB have been completed. **There are no constraints for proceeding with the construction works.** There is a high probability of chance finds in these areas.	Replicable	High
HRM 4	Settlement	Late Byzantium	Serik K3 Interchange Access Road Km 8+800 Antalya/Serik/Belpınar	177 m	No - does not overlap	Late Period Settlement: Likely dating back to the 14th-15th centuries, this settlement is characterized by a distinct elevation. The site is situated between a stream bed and a road. The surface is scattered with dense tile fragments and sherds of daily-use vessels.	**Non-registered**	**ARHB permitting process is <u>complete</u>.** The identified area has been reported to the Museum Directorate, and the procedures at the ARHB have been completed. It was evaluated by the Board and was not registered. **All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works**.	Replicable	Low
HRM 5	Cemetery	Late Ottoman	Serik K1 Interchange Km 52+500 Antalya/Serik/Deniztepesi	Within	Yes-partially	It is a cemetery spread over a vast area, located within the borders of Antalya, Serik, Deniztepesi neighborhood, on parcel 139-5/135-9. The land registry record, when queried from the system, identifies the area as a cemetery. It is likely an Early Republic to modern-era cemetery.	**Non-reigstered**	**ARHB permitting process is <u>ongoing</u>.** In order to carry out works in these areas, a Technical Justification Report has been submitted to the ARHB. The consultant academics within the ARHB, in line with the relevant legislation and taking into account the opinion of the Museum Directorate, have completed their evaluation and the permits for excavation have been obtained. The necessary permits have been obtained from the ARHB, and the **salvage excavations will commence.**	Replicable	Low
HRM 6	Building Remains	Roman	Serik K1 Interchange Km 52+500 Antalya/Serik/Deniztepesi	Within	Yes-partially	Remains of an architectural structure, possibly from the Roman Period, likely representing a frontier garrison settlement. A dense accumulation of rubble stone and visible wall rows, which may belong to the structure, are present on the surface. Additionally, numerous roof tile fragments and a small number of sherds from daily use vessels have been observed.	**1st Degree**	**ARHB permitting process is <u>ongoing</u>.** Design change was completed before the trial pits study.In order to carry out works in these areas, a Technical Justification Report has been submitted to the ARHB. Trial pits will start.	Replicable	High
HRM 7	Tumulus	Roman	Serik K1 Interchange Km 52+500 Antalya/Serik/Sarıabalı	70 m	Yes-partially	Tumulus: A row of stones, possibly belonging to the wall of the tomb, is visible on the surface. In the vicinity of the artificial hill, there are densely packed roof tile fragments and a sparse number of ceramic pieces from daily use vessels.	**1st Degree**	**ARHB permitting process is <u>complete</u>.** **All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works.**	Replicable	High

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
HRM 8	Manavgat Natural Site Border	Archeological or Natural Site Border	Viaduct-4 Km 56+000	Within	Yes - fully	Manavgat Natural Preservation Area	Natural Preservation Area	**Permitting process is complete.** All necessary permits have been obtained and there are no constraints for proceeding with the construction works.	Non-replicable	Medium
HRM 9	Late Roman Settlement	Late Roman	Km 59+000 Antalya / Manavgat/ Taşağıl	Within	Yes - fully	Late Roman Settlement: Due to its location, the settlement is believed to have been constructed for surveillance purposes. It is situated on a hill overlooking the valley and features a dense layer of rubble stone that may belong to architectural structures. Additionally, roof tile fragments and ceramic fragments from daily use vessels are visible on the surface.	**Non-registered**	**ARHB permitting process is complete.** All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works It was evaluated by the Board and was not registered. Board permit has been obtained.	Replicable	Low
HRM 10	Settlement	-	Km 62+000 Antalya / Manavgat Taşağıl	Within (Tunnel)	Yes - fully	1st Degree Registered Archaeological Site	**1st Degree**	**ARHB permitting process is complete.** **All necessary permits have been obtained from the Regional Conservation Board, and there are no constraints for proceeding with the construction works**	Non-replicable	High
HRM 11	Archaeological Settlement	Roman	Km 62+750 Antalya / Manavgat Taşağıl	Within	Yes-partially	Late Roman Settlement: Features a dense layer of rubble stone that may belong to architectural structures. Additionally, roof tile fragments and ceramic fragments from daily use vessels and terra sigilatta are visible on the surface.	**Non-registered**	**ARHB permitting process is complete.** All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works It was evaluated by the Board and was not registered.	Replicable	Low
HRM 12	Necropolis	Roman	Taşağıl Interchange Km 67+000 Antalya / Manavgat Hocalar	174 m	No - does not overlap	Roman Period Necropolis: In addition to high-quality ceramic and tile fragments dating back to the 4th-6th centuries AD, many slabs and covering stones that may belong to graves are present on the surface and in the section. It is anticipated that there is a nearby settlement area associated with this necropolis.	**1st Degree**	**ARHB permitting process is complete.** All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works	Replicable	High
HRM 13	Settlement	Roman	Taşağıl Interchange Km 67+000 Antalya / Manavgat Hocalar	800 m	No - does not overlap	Roman Period Settlement: No traces of architecture are visible on the surface. Thin-walled, high-quality ceramic fragments dating back to the 4th-6th centuries AD have been found. The site is situated on a hillside in a sheltered location overlooking the surrounding area.	**Non-registered**	**ARHB permitting process is complete.** All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works It was evaluated by the Board and was not registered. Route change was completed before the permit process	Replicable	Low
HRM 14	Cemetery	Early Republic	Taşağıl Interchange Km 67+000 Antalya / Manavgat Hocalar	916 m	No - does not overlap	Hocalar Köyü Cemetery: Early Republican and modern cemetery.	**1st Degree**	**ARHB permitting process is complete.** All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works Route change was completed before the permit process.	Replicable	High
HRM 15	Cemetery	Early Republic	Taşağıl Interchange Access Road Antalya /Manavgat Taşağıl	Within	Yes-partially	Cemetery: Early Republican and modern cemetery. Use of spolia in some graves.	**1st Degree**	**ARHB permitting process is ongoing.** The necessary permits have been obtained from the ARHB), and the **salvage excavations will commence.**	Replicable	High
HRM 16	Tumulus and Necropolis	Roman	Km 70+400 Antalya /Manavgat Gündoğdu	Within (Tunnel)	Yes-partially	Tumulus-Necropolis: In addition to high-quality ceramic and glass fragments from the 4th-5th centuries AD, a large number of tile fragments are also visible on the surface.	**1st Degree**	**ARHB permitting process is complete.** All necessary permits have been obtained from the Regional Conservation Board, and there are no constraints for proceeding with the construction works	Non-Replicable	High
HRM 17	Settlement	Roman	Km 70+500 Antalya /Manavgat Yavrudoğan	125 m	No - does not overlap	Tumulus-Necropolis Area: Various ceramic fragments from different shapes are visible on the surface, including bases of amphorae, handle pieces from	**Non-registered**	**ARHB permitting process is complete.** All necessary permits have been obtained from the ARHB, and there are no constraints for proceeding with the construction works It was evaluated by the Board and was not registered.	Replicable	Low

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
						very large amphorae, and fragments of daily use vessels.				
HRM 18	Mound	Roman	Manavgat K1 İnterchange Km 83+500 Antalya /Manavgat Yukarıışıklar	313 m	No - does not overlap	Registered Archaeological Site: Dense ceramic and tile fragments from the Roman Period are visible on the surface. Illegal excavation pits containing numerous rubble stones have been identified in the area.	**1st Degree**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Non-Replicable	High
HRM 19	Manavgat Waterfall Protected Area	-	Manavgat K3 İnterchange Km 88+000	2900 m	No - does not overlap	Registered Natural Site: Manavgat Waterfall Preservation Area. Although it is not in direct contact with the Project area, it falls within the 400 m corridor. Due to its status as a natural asset, the Antalya Environment and Urbanization Provincial Directorate and the Antalya Board of Preservation must be informed before any work is conducted.	Natural Preservation Area	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Non-Replicable	Medium
HRM 20	Aqueduct	Roman	Manavgat K2 Interchange Km 84+000 Antalya /Manavgat Sarılar	1780 m	No - does not overlap	Registered Archaeological Site: This is the aqueduct supplying water to the ancient city of Side. Since the Project involves a first-degree archaeological site, the opinion of the Antalya Board of Preservation must be obtained before proceeding with any work.	**1st Degree**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Non-Replicable	High
HRM 21	Settlement	Roman	Manavgat Interchange Access Road Km 83+000 Antalya /Manavgat Yukarıışıklar	1433 m	No - does not overlap	Registered Archaeological Site: This is the aqueduct supplying water to the ancient city of Side. Since the Project involves a first-degree archaeological site, the opinion of the Antalya Board of Preservation must be obtained before proceeding with any work.	**1st Degree**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Non-Replicable	High
HRM 22	Aqueduct	Roman	Manavgat K3 Interchange Km 86+000	2200 m	No - does not overlap	Aqueduc Feet: For reference see kültürvarlıkları.gov.tr. However, no archaeological evidence was encountered during the examination.	**Non-registered**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Replicable	Low
HRM 23	Cemetery	Late Ottoman	Manavgat K4 Interchange Km 82+000 Antalya /Manavgat Hatipler	3900 m	No - does not overlap	Hatipler Village Cemetery Area: This site encompasses a cemetery from the Late Ottoman to the Early Republican period, as well as modern graves. Reused columns and column capitals are incorporated into the graves, and spiralled, monolithic columns are also present. Additionally, there are quilted gravestones dating from the Late Ottoman period.	**1st Degree**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Replicable	High
HRM 24	Mound	Roman	Manavgat K5 Interchange Km 81+000 Antalya /Manavgat Hatipler	4500 m	No - does not overlap	Mound: The site is situated at a high elevation relative to the surrounding settlement. Ceramic fragments from the Late Roman to Early Byzantine period have been observed in great numbers. However, due to the area being a cultivated field, a detailed examination could not be conducted.	**3rd Degree**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Non-Replicable	Medium
HRM 25	Tumulus	Roman	Manavgat K4-K5 Interchange Km 81+000 Antalya /Manavgat Hatipler	3100 m	No - does not overlap	Tumulus: A small number of ceramic fragments dating back to the Late Roman to Early Byzantine period are visible on the surface.	**Non-registered**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Replicable	Low
HRM 26	Hilltop Settlement	Roman	Manavgat K4-K5 Interchange Km 81+000	3300 m	No - does not overlap	Mound: A large number of ceramic fragments dating to the Late Roman period are visible on	**1st Degree**	**Process is <u>complete.</u>** As a result of the route change, the area has been excluded from the project's impact corridor	Non-Replicable	High

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
			Antalya /Manavgat Hatipler			the surface. No traces of architecture have been observed.				
HRM 27	Settlement	Roman	Km 84+400 Antalya /Manavgat Yukarıışıklar	84 m	No - does not overlap	Mound: A large number of ceramic and tile fragments dating back to the Roman period are visible on the surface and in the section. No traces of architecture have been observed.	**3rd Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	Medium
HRM 28	Tumulus	Roman	Km 85+900 Antalya/Manavgat Bucakşeyhler	Within	Yes - fully	Tumulus: The surface contains a small number of ceramic pieces dating back to the Roman period. The dense presence of stream stones at the top of the hill suggests that the hill was intentionally created.	**Non-registered**	**ARHB permitting process is complete.** It was evaluated by the Board and was not registered. And trial pits was completed and no archaeological material. Construction activities can be implemented	Replicable	Low
HRM 29	Aqueduct	Roman	Km 86+500 Antalya/Manavgat Bucakşeyhler	74 m	No - does not overlap	Registered Archaeological Site: This is the aqueduct supplying water to the ancient city of Side. Although it is not in direct contact with the Project area, it falls within the 400 m corridor.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	High
HRM 30	Fountain	Ottoman	Km 86+500 Antalya/Manavgat Bucakşeyhler	128 m	No - does not overlap	Fountain: An Ottoman-period fountain structure. The stones used in the construction were sourced from the nearby aqueduct.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Replicable	Hig
HRM 31	Necropolis	Roman	Km 87+00 Antalya/Manavgat Bucakşeyhler	7 m	Yes-partially	Necropolis: A necropolis area. Skeletal remains and numerous covering tile fragments were found in the sections.	**Non-registered**	**ARHB permitting process is ongoing.** Design change was completed The area is outside of the project's expropration corridor.	Replicable	Low
HRM 32	Church Remains	Roman	Km 87+100 Antalya /Manavgat/Bucakşeyhler	Within	Yes-partially	Registered Archaeological Site: The architectural walls from the Roman period are still standing, and a large number of ceramics and tile fragments from the same period can be observed in the surrounding area.	**1st Degree**	**ARHB permitting process is ongoing.** The necessary permits process is ongoing, according to the opinion of Antalya Regional Board for the Protection of Cultural Heritage (RHB), and the salvage excavation is ongoing.	Replicable	High
HRM 33	Settlement	Roman	Km 87+700 Antalya/Manavgat Bucakşeyhler	260 m	No - does not overlap	Mound: The surface features a dense concentration of high-quality ceramic pieces dating back to the Roman period. However, no architectural remains have been observed.	**1st Degree**	**Pocess is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	High
HRM 34	Cemetery	Ottoman	Km 87+500 Antalya/Manavgat Bucakşeyhler	160 m	No - does not overlap	Cemetery Area: Despite the intensive use of the cemetery, no uniform orientation of the graves was observed. It is believed that the cemetery was in use during both the Byzantine and Ottoman periods.	**Non-registered**	**Process is complete.** It was evaluated by the Board and was not registered. The area is outside of the project's expropration corridor.	Replicable	Low
HRM 35	Building Remains	Ottoman	Km 88+200 Antalya/Manavgat Bucakşeyhler	1 m	Yes-partially	Building: The main walls are visible on the surface. However, due to the location, the area surrounding the structure could not be thoroughly examined. It is located along the camp road alignment.	**1st Degree**	**ARHB permitting process is complete.** All necessary permits have been obtained from the Regional Conservation Board, and there are no constraints for proceeding with the construction works	Replicable	High
HRM 36	Rural Settlement	Ottoman	Km 89+800 Antalya /Manavgat Ulukapı	65 m	No - does not overlap	Area with Pottery: Sparse pottery and tile fragments are visible on the surface. However, no architectural remains have been identified.	**Non-registered**	**Process is complete.** It was evaluated by the Board and was not registered. The area is outside of the project's expropration corridor.	Replicable	Low
HRM 37	Settlement	Roman	Km 92+200 Antalya /Manavgat Aşağıışıklar	Within	Yes-partially	Roman Period Settlement: A dense accumulation of rubble stones, likely belonging to architectural structures, is visible on the surface. Additionally, a large number of tiles and fragments of daily use vessels	**1st and 3rd Degree**	**ARHB permitting process is ongoing.** An application has been submitted to the Antalya Regional Board for the Protection of Cultural Heritage (ARHB) regarding this area, consisting of 1st Degree and 3rd Degree sites. The ARHB required	Non-Replicable	High

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
						from the 4th-5th centuries AD are present throughout the area.		that archaeological trial (sondaj) excavations be carried out and the results submitted to the Board. For the 1st degree site, following the route revision (design change), the alignment has been shifted outside the boundaries of the 1st-degree archaeological site and impact on this site has been avoided However, for the 3rd degree site, since no route revision (design change) could be implemented within the 3rd-degree registered area, archaeological trial (sondaj) excavations, including vegetation clearance, will be undertaken at this site in accordance with the applicable legislation. Following the completion archaeological trial excavation and vegetation clearance, a final decision will be obtained from ARHB.		
HRM 38	Settlement	Roman	Km 95+600 Antalya /Manavgat Aksaz	65 m	Yes-partially	Roman Period Settlement: The settlement, which dominates the valley, features a wide range of material dating from the Early Roman Period to the 4th-5th centuries AD. Numerous high-quality ceramic fragments, in various forms, are found on the surface, along with tile and glass pieces.	**1st Degree**	**Process is complete.** Design change was completed	Non-replicable	High
HRM 39	Tumulus	Roman	Km 102+500 Antalya /Manavgat Hacıobası	35 m	Yes-partially	Tumulus: Tile fragments dating back to the Roman Period are visible on the surface. The site is situated on the edge of a slope filling area.	**Non-registered**	**Process is complete** It was evaluated by the Board and was not registered	Replicable	Low
HRM 40	Cemetery	Late Ottoman	Manavgat Interchange East Access Road Antalya /Manavgat Hacıobası	32 m	Yes-partially	Cemetery: This is a Late Ottoman period cemetery area with a dense number of burials observed throughout the site.	**1st Degree**	**ARHB permitting process is ongoing.** Design Processes are ongoing Salvage excavation and relocation will be carried out for certain graves after the necessary permits have been obtained. The expropriation corridor remains within the cemetery limits; however, no graves are affected according to the latest measurements. This has been ensured through a design change implemented along both the main route and the access road, effectively avoiding any physical interaction with the burial area.	Replicable	High
HRM 41	Church or Build Remains	Byzantium	Km 104+500 Antalya /Manavgat Uzunlar	61 m	No - does not overlap	Byzantine Period Church-Administrative Building: The structure, with its main walls standing approximately 2 meters high, features an apsidal section on its eastern facade. Numerous roof tile fragments are visible on the surface.	**1st Degree**	**Process is complete.** Design change was completed The area is outside of the project's expropriation corridor.	Replicable	High
HRM 42	Settlement	Roman	Km 105+000 Antalya /Manavgat Uzunlar	Within	Yes-partially	Mound: The surface of the settlement, located in a sheltered area by the river, contains a very dense concentration of ceramic and glass fragments dating back to the Late Roman period. The slope facing the river consists of natural rock, while the rear section is a landfill area suitable for settlement.	**1st Degree**	**ARHB permitting process is ongoing** Vegetation clearance has been completed, the excavation contractor has been appointed, and excavation works was completed. A report which is inclueded resul of excavation was submitted Museum Directorate. Final decision is awaited.	Replicable	High
HRM 43	Cemetery	Early Republic	Km 108+750 Antalya /Manavgat Kadılar	60 m	No - does not overlap	Cemetery Area: Early Republican Period and modern cemetery. As the reference point is located adjacent to the cemetery, it is believed that the route passes through the cemetery. In this case, it must be remembered that Cemetery Laws will apply on anything related to the area.	**Non-registered**	**Process is complete.** It was evaluated by the Board and was not registered. The area is outside of the project's expropriation corridor.	Replicable	Low
HRM 44	Historical Plane Tree	-	Km 109+600	24 m	Yes-partially	Historical Plane TreeAs a natural asset, notification should be made to the Antalya Provincial	**Non-registered**	**Process is complete.**	Replicable	Low

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
			Antalya /Manavgat Kadılar			Directorate of Environment and Urbanization. Since the plane tree meets the criteria for a natural asset, with a diameter of 2 m and a height of 15-17 m, it must be protected in situ.				
HRM 45	Cemetery	Late Ottoman	Km 112+250 Antalya /Manavgat Yalçıdibi	42 m	Yes-partially	Cemetery: The area is a late Ottoman, early Republican, and modern cemetery. Numerous skullcap tombstones are also notable within the cemetery.	**Non-registered**	**Process is complete.** Design change was completed	Replicable	Low
HRM 46	Yalçıdibi Waterfall	-	Km 112+250 Antalya /Manavgat Yalçıdibi	168 m	No - does not overlap	Registered 1st Degree Site: Yalçıdibi Waterfall is a registered natural asset.	Natural Preservation Area	**Process is complete.** The area is outside of the project's expropration corridor.	Non-replicable	Medium
HRM 47	Çardaktepe	Roman / Byzantium	Alarahan K2 Interchange Access Road Km 116+000 Antalya/Alanya Alara	266 m	No - does not overlap	Registered 1st Degree Archaeological Site: This site is registered by the Antalya Preservation Board. The main walls of the structure are visible on the surface. The opinion of the Board must be obtained before construction.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-replicable	High
HRM 48	Building Remains	Roman	Konaklı K1 Interchange Access Road Antalya/Alanya Payallar	9 m	No - does not overlap	Registered 1st Degree Archaeological Site: Building remains are visible on the surface.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Replicable	High
HRM 49	Building Remains	Roman / Byzantium	Konaklı K1 Interchange Access Road Antalya/Alanya Emişbeleni	Within	Yes-partially	Registered 1st Degree Archaeological Site: There is no indication of the function of the structure, whose main walls are preserved up to 3 meters. The structure is located within a 400-meter corridor.	**1st Degree**	**ARHB permitting process is ongoing.** The route has minimal contact with the building remain's conservation area. Design changes are ongoing there.	Replicable	High
HRM 50	Building Remains	Roman / Byzantium	Km 134+000 Antalya/Alanya Emişbeleni	113 m	No - does not overlap	Building: There is no indication of the function of the structure, with only 3 meters of the main walls preserved.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Replicable	High
HRM 51	Cemetery	Early Republic	Km 136+200 Antalya/Alanya Toslak	17 m	Yes-partially	Cemetery: Early Republican and modern cemetery. There may also be late Ottoman period graves in the area, which should be verified through further examination.	**Non-registered**	**Process is completed.** It was evaluated by the Board and was not registered.	Replicable	Low
HRM 52	Settlement	-	Km 136+000 Antalya/Alanya Toslak	122 m	No - does not overlap	Registered 1st Degree Site	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	High
HRM 53	Building Remains	Roman / Byzantium	Km 140+000	39 m	No - does not overlap	Registered 1st Degree Archaeological Site: The presence of an apse on the eastern facade of the building, with main walls preserved up to 3-4 meters, indicates that the structure may have been a church.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	High
HRM 54	Building Remains	Roman / Byzantium	Alanya West Interchange Access Road End Antalya/Alanya Telatiye	55 m	No - does not overlap	Registered 1st Degree Archaeological Site: Numerous well-preserved structures are observed in the area near the coast.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	High
HRM 55	Building Remains	Roman / Byzantium	Alanya West Interchange Access Road End Antalya/Alanya Telatiye	178 m	No - does not overlap	Registered 1st Degree Archaeological Site: The structure is situated in an elevated location with a commanding view of the surrounding area. Its main walls are preserved up to a height of 4 meters.	**1st Degree**	**Process is complete.** The area is outside of the project's expropration corridor.	Non-Replicable	High

HRM ID	Type	Period	Location	Distance with respect to Centreline of the Road*	Does it overlap with Project's expropriation corridor?	Description	Registration Status	Current Status	PS 8 Heritage Value	Value of the Heritage Asset
HRM 56	Building Remains	Roman / Byzantium	Km 56+750 Antalya / Manavgat Çakış	Within	Yes - fully	Registered 1st Degree Archaeological Site : The relevant matter was evaluated by the Regional Conservation Council on 26.12.2024. With Council Decision No. 6162842 dated 31.12.2024, the issue was approved by the Council, and the project design for this section was endorsed.	**1st Degree**	**Process is <u>complete</u>.** Design change was completed	Replicable	High
HRM 57	Settlement	Roman / Byzantium	Km 120+800 Antalya/Alanya İncekum	Within	Yes-partially	Registered 1st Degree Archaeological Site: The updated registration list was obtained from the Conservation Council. It has been observed that, in this section of the route, there is partial overlap with an archaeological conservation site. The project design team must revise the alignment to avoid encroachment on the registered site boundaries. XIII.3.3. Intangible Cultural Heritage Baseline

Türkiye is a multicultural country. The people of Türkiye consisted of local people and immigrants from the Balkans, Caucasus, Crimea and Central Asia who had settled in the country since the 19th century. The people who came to Türkiye in the late Ottoman period and early Republic period included Muslim immigrants, Turkish-speaking Crimean Tatars and Nogais from the Balkans previously ruled by the Ottomans; Azeris, Uzbeks, Turkmen, Kazakhs, Kyrgyz and other Inner Asian Turkic peoples expelled by the Russian Empire and the USSR, and later the war-torn Turkic Afghans as well as peoples of the North and South Caucasus, such as Circassians, Abkhazians, Dagestanis, Karachay-Balkarla, Chechens and Muslim Georgians. Besides Turkish-speaking immigrants, Bosnians, Pomaks, Albanians, Macedonians, and Greek Muslims, people who do not speak Turkish, are also among the immigrants from the Balkans.

Among the locals, Turks are the majority, including rural and urban Turks, former nomadic Turkmen and semi-nomadic Yoruks. The second main indigenous groups are the Kurds and Zazas, who speak Western Iranian languages. There are also Laz people who speak a South Caucasian language. Sunni and Nusayri Arabs follow next. There are also minorities in Türkiye, such as some non-Muslim Orthodox Greeks, Gregorian and Catholic Armenians, Jews, Assyrians and Chaldeans, and a small number of Molokans (Russian peasants who refuse to obey the Russian Orthodox Patriarchate).

The majority of the population in Türkiye is Muslim (98.8%). There are two main Muslim sects: Sunnis and Alawites. Sunni Turks and Kurds predominate in Türkiye, but Turkish, Kurdish, and Arab Alevis have a significant population (approximately 20% of the total population). Alevi ceremonies are performed in Turkish, whether they are Turkish or not. Although Alawite worship is related to Imam Shia, it differs from regular Shiite doctrine in belief and creed.

In addition to respecting the formal adaptation of the faith, such as a regular mosque or church attendance, the people in Türkiye have also developed beliefs and ceremonial practices based on their local environment, which can be considered the beginning of folk faith. At the centre of such practices is the creation of saints in Christianity, saints (Evliya) in Sunni Islam, or cultural personalities such as "dede" or "ocak" in Alevism. The believers accept them as intermediaries between the folk and the divine power. The tombs or shrines (türbe) of these persons are somehow attributed to specific locations where those people lived for some part of their lives or their whole lives. In addition, the tombs or shrines of others, called Sayyids, who are believed to be descendants of the Prophet Muhammed, are accepted as sacred. Such people, who are believed to be holy, are buried where they died or had shed blood. Places where those sacred personalities were buried are visited by people following their death. People visiting those places generally practice certain forms of worship or prayers in the hope that their wishes will come true. People also visit these places during faith fasts, and prayers are made to these holy people for good deeds to gain merit in the eyes of God. People additionally visit these places for other reasons: e.g., a woman who cannot give birth prays to have children, to heal a person who is sick, another in distress to overcome difficulties, etc. The tombs of these people are then converted into dome-shaped buildings surrounded by rocks to protect them and provide people with a more comfortable environment for prayers/worship.

Sometimes, the names or stories of those who lie in those localities are forgotten or unknown, but people continue to visit these places, pray, and offer offerings. In some places, graves belonging to forgotten Christian saints or monks were also known to be converted to Muslim saints over time, or people who converted to Islam continued their beliefs under the cover of traditional Islam. It is sufficient for the person performing these ceremonial practices to know that a holy or saintly person is lying there no matter to which religion they belong.

In some temples and shrines, a vow is made to fulfil a wish. If the wish comes true, the place is visited once again, and an animal is sacrificed to the spirit of the intermediary. Sacrifice meat and other prepared meals are distributed to neighbours, especially those in need. In some places in Türkiye, tree

worship or tree cult practices are also practised. Among them, the most popular practice is to tie a piece of cloth to the tree with the wish.

In addition, religious or non-religious periodic and ceremonial practices do exist, such as village festivals, pro bono village entertainments, sacrifice, ceremonies (such as circumcision and baptism), mawlids, Eid (Ramadan and Kurban) and Friday prayers, holy nights (kandil), martyr days and rain prayers. These traditions were created as an exception from religious celebrations and ceremonies such as festivities, Hıdrellez, Bayram and Friday prayers, and harvest festivals.

Nowruz is celebrated every year on March 21 in the centrums of the settlements or on the fairgrounds. The common practice in Nowruz is jumping over a fire, painting eggs, and competing in egg-tossing games.

The 32nd General Conference of the United Nations Educational, Scientific and Cultural Organization, whose short name is UNESCO, held in Paris between 29 September and 17 October 2003, adopted the "Convention for the Safeguarding of the Intangible Cultural Heritage" on 17 October 2003. The Convention was accepted unanimously at the session of the Grand National Assembly of Türkiye dated 19.01.2006, under the name "Law on Approval of the Convention for the Protection of Intangible Cultural Heritage" (No: 5448) that was published in the Official Gazette dated 21 January 2006 and numbered 26056 and entered into force in Türkiye. The procedure of becoming a party was completed on 27 March 2006.

There are Intangible Cultural Heritage Lists that were established in accordance with Articles 16, 17 and 18 of the Convention, whose names are as follows:

- Representative List of the Intangible Cultural Heritage of Humanity
- List of Intangible Cultural Heritage Requiring Urgent Protection
- A Record of Good Practices in Conservation

The first writings of Türkiye took place with the inclusion of previously announced Masterpieces on the Representative List of Intangible Cultural Heritage within the scope of Article 16 at the Third Ordinary Meeting of the Intergovernmental Committee held in Istanbul in 2008.

As of December 2022, Türkiye has a total of 30 items registered in the Intangible Cultural Heritage List, which can be listed as follows (see **Error! Reference source not found.**):

Table XIII-8 UNESCO Intangible Cultural Heritage List

Representative List of the Intangible Cultural Heritage of Humanity	
1	Meddah (Public Storyteller) Tradition (2008)
2	Mevlevi Whirling (Sema) Ceremonies (2008)
3	Âşıklık (Minstrel) Tradition (2009)
4	Karagöz (2009)
5	Nowruz (Joint file with Azerbaijan, India, Iran, Kyrgyzstan, Uzbekistan and Pakistan (2009) (in 2016, the file was expanded with the participation of Afghanistan, Azerbaijan, India, Iraq, Iran, Kazakhstan, Kyrgyzstan, Uzbekistan, Pakistan, Tajikistan and Turkmenistan)
6	Traditional Conversation Meetings (Yaren, Barana, Sıra Nights and others, 2010)
7	Alevi-Bektashi Whirling Ritual (Semah) (2010)
8	Kırkpınar Oil Wrestling Festival (2010)
9	Traditional Ceremonial Keşkek (2011)
10	Mesir Paste Festival (2012)

Representative List of the Intangible Cultural Heritage of Humanity	
11	Turkish Coffee and Tradition (2013)
12	Ebru: Turkish Decoration Art of Paper (2014)
13	The tradition of baking "Thin Bread" and Sharing: referred to as Lavaş, Katrıma, Jupka or Yufka (joint file with Azerbaijan, Iran, Kazakhstan, Kyrgyzstan and Türkiye) (2016)
14	Traditional Art of Decorated Tile (2016)
15	Spring Festival Hıdırellez (joint file with Macedonia) (2017)
16	Dede Korkut-Korkut "The Ancestor" Heritage: Culture, Legends and Music (joint file with Azerbaijan and Kazakhstan, 2018)
17	Traditional Turkish Archery (2019)
18	Miniature Art (joint file with Azerbaijan, Iran and Uzbekistan) (2020)
19	A traditional game of wit and strategy: Togyzqumalaq, Toguz Korgool, Mangala / Gocme (joint file with Kazakhstan and Kyrgyzstan) (2020)
20	Hüsn-i Hat, Traditional Calligraphy in Islamic Art in Türkiye (2021)
21	Tea Culture: Symbol of Identity, Hospitality and Social Interaction (joint file with Azerbaijan, 2022)
22	Traditional Production of Silk for Sericulture and Weaving (joint file with Afghanistan, Azerbaijan, Iran, Tajikistan, Turkmenistan and Uzbekistan, 2022)
23	Nasreddin Hodja/Molla Nesreddin/Molla Ependi/Apendi/Afendi Kozhanasyr Joke Telling Tradition (joint file with Azerbaijan, Kazakhstan, Kyrgyzstan, Tajikistan, Turkmenistan, Uzbekistan, 2022)
24	Tezhip/Tazhib/Zarhalkori/Tezhip/Naqqoshlik (joint file with Azerbaijan, Islamic Republic of Iran, Tajikistan and Uzbekistan, 2023)
25	Iftar/Eftari/Iftar/Iftor and Sociocultural Traditions (joint file with Azerbaijan, Islamic Republic of Iran and Uzbekistan, 2023)
26	Balaban/Mey Craftsmanship and Performing Art (joint file with Azerbaijan, 2023)
27	Mother of Pearl Inlay Workmanship (joint file with Azerbaijan, 2023)
UNESCO List of Intangible Cultural Heritage Requiring Urgent Protection	
28	Whistled Language (2017)
29	Traditional Ahlat Stone Workmanship (2022)
30	Traditional Knowledge, Methods and Practices on Olive Cultivation (2023)

Yörük Culture (Karakeçeliler)

The Karakeçilis, members of the tribe that played a pioneering role in establishing Anatolia as a Turkish homeland and later founding a global empire (Ottomans), first entered Anatolia under the leadership of Ertuğrul Gazi in the 6th century of the Hijra. There are various interpretations regarding the origin of the name "Karakeçili". The most widely accepted explanation is that the tribe took its name during the conquest of Karacahisar when Ertuğrul Gazi reportedly called out, "Come on, Karakeçili Yörüks, come on, Alps (my warriors)", during their military manoeuvres where they tied lights to the horns of their black sheep (Kara keçi in Turkish) and covered their tents (alayçık) with black felt. The Karakeçilis themselves believe that their name originated from this event. The Karakeçili tribe is a branch of the Kayı tribe, which is considered the foremost of the four branches of Günhan (the eldest son of Oğuz Han) from the Bozoklar, the senior line among the 24 Oğuz tribes. The Mongol invasion was the key factor driving the migration of the Karakeçili tribe to Anatolia. As a large and influential tribe, they migrated under the leadership of Ertuğrul Bey, along with other tribes from the Kayı lineage. This migration laid the foundation for a long-lasting and powerful empire, which would dominate three continents, with its centre in Anatolia. The Ottoman sultans highly regarded the Karakeçili tribe. Yavuz Sultan Selim, in particular, honoured them by naming the Karakeçili tribe the 'Harameyni Şerifeyn Tribe' during his reign.

Sultan Abdulhamid II referred to the Karakeçilis as his compatriots and once introduced them to the German Emperor Wilhelm as his relatives. Today, the Karakeçilis are dispersed across various regions

and districts throughout Anatolia. Historian Yusuf Halaçoğlu notes that "There are exactly 260 Karakeçili communities within the borders of Türkiye, not as settlements, but as distinct tribal groups."Highlighting the significant presence of the Karakeçilis in terms of population. Presently, Karakeçili communities can be found in almost every region of Türkiye, including areas such as Kırıkkale-Karakeçili, Ankara-Beypazarı, Eskişehir, Eskişehir-Sivrihisar, Sultanözü, Sivas, Kırşehir, Muğla, Antalya, Bilecik, Balıkesir, Kütahya, Bursa, Urfa, Urfa-Siverek, Urfa-Suruç, Gaziantep, Bingöl-Simsor, Denizli, Çorum, Uşak, and Samsun.

The Yörüks have played a significant role in preserving the richness of the Turkish language. They have transmitted what is often referred to as 'pure Turkish' in its unaltered form, maintaining the language's authenticity across generations. Furthermore, they have succeeded in preserving and passing down the oral traditions of Turkish culture, including stories, tales, and legends, through a vibrant oral literature tradition.

Traditional "Düğmeli" Construction System

This traditional construction system, commonly known today as "düğmeli' (buttoned)", is also referred to as "pişduvanlı", "pişduvanlı", "pişduvan duvar", "pişduvanlı duvar", or "hatıllı duvar (beam wall)". While it is the characteristic and most widely used construction technique in the Akseki and İbradı regions, it also represents one of the most original, creative, and distinctive systems in Turkish vernacular architecture. This method involves the reinforcement of dry-stone walls, built without mortar or binding materials, using wooden beams known as "hatıl" or "pişduvan" to form the main body of the building. Although it may appear simple, it is a highly functional construction technique that requires significant skill and results in incredibly durable structures. In addition to traditional houses, this technique has been widely employed in the construction of various other structures, including mosques, tombs, village rooms, vineyard houses, madrasahs, schools, and pekmez roofs.

Sarıhacılar Village, located in the Akseki region and boasting a 700-year history, was declared a protected site by UNESCO in 1994. The village is known as a settlement of greater historical importance in the past than the current centre of Akseki. Situated along the Silk Road, it was positioned on the main trade route connecting the Mediterranean, particularly via Manavgat and Alanya, with the interior of Anatolia. As a result, Sarıhacılar was highly developed in trade during this period. The architecture of the buildings reflects this commercial significance, with the ground floors of many structures historically housing shops, such as jewellers and drapers, where trade activities were once conducted.

Elmalı Yeşilyayla Oil Wrestling

Elmalı Yeşilyayla Oil Wrestling holds the distinction of being the oldest oil wrestling event in Türkiye, although it ranks second after Kırkpınar in terms of organisational history. The event's foundation dates back to 1419 when the land known as Musalla Çevrik (the present-day site of Yeşil Mosque) was designated as the wrestling field. This land was integrated into the "Toramanlar Vakfı (Foundation)" real estate holdings, established by Nuh Çelebi.

It is believed that the tradition of wrestling among the Turks dates back to ancient times. Even today, wrestling remains a prominent feature in certain regions, where it is performed during weddings and Hıdrellez celebrations, with widespread participation from the younger generation. In modern culture, the wrestling tradition continues to uphold the principles of fostering healthy, athletic, and morally upright individuals within Turkish society.

Elmalı is one of the regions that has best preserved the wrestling tradition. Historically, until the mid-1970s, it was common for residents and villagers to gather in Cumhuriyet Square to watch performances by the 'Mehter Takımı' (Ottoman Army Band) and the theatrical play 'Hart Hart Deve' (Camel). The Elmalı Oil Wrestling event, nowadays, has evolved into a cultural and artistic festival, typically taking place in the evening in a lively and festive atmosphere. Today, symposiums and exhibitions are held a week

before the wrestling competitions begins. Additionally, artists are invited, and public concerts are organised in the evenings, a few days prior to the wrestling events. The historic Elmalı Yeşil Yayla Oil Wrestling occurs annually during the first week of September.

Döşemealtı Carpeting

Carpets woven on looms known as "ıstar" in the Döşemealtı district of Antalya are referred to as "Döşemealtı carpets" in the literature. These carpets, which have been awarded a geographical indication and whose oldest examples are displayed in the Antalya Museum, hold a distinctive place within the Turkish carpet-weaving tradition. Döşemealtı carpets are notable for their dark colours, kilim-patterned motifs, short piles, and dimensions that make them easily transportable.

Contrasting colours are a hallmark of Döşemealtı carpets. Traditionally, frequently used colours include navy blue, burgundy, red, dark green, pistachio green, camel, light and dark blue, orange, melon, dusty rose, white, and black. The most common background colours are red, navy blue, burgundy, and green.

The edge borders of traditional Döşemealtı carpets are named based on the patterns and motifs used in the central field. The border is commonly called "su (water)" in the local region.

Iftar Invitation Tradition in Ceceler Neighborhood

Ceceler Neighborhood is a rural settlement located in the Akseki District to the east of Antalya. The tradition of offering an iftar (the meal to break the fast during Ramadan) in this community dates back to old times and has continued to the present, though it has evolved with various changes over time.

Iftars are organised collectively and systematically in the Village Hall. A team of cooks prepares the meals in the kitchen of the historic Village Hall. These individuals also serve the food, clean, and wash the dishes, with support from the villagers at every stage of the process. The person hosting the iftar provides the cooks with a menu and covers all the expenses for the day. Meals are delivered to the homes of those who are too ill or elderly to attend the gathering. Additionally, many people from the district and nearby settlements are invited to participate in the iftar.

Canbazhane / Körmük Tradition

Canbazlık (acrobatics) refers to the profession or skill of individuals known as "canbaz (acrobat)" who perform dangerous stunts on ropes, horses, cars, and other apparatus. This art, which is one of the traditional performing arts of Anatolia and has roots tracing back to ancient times, is preserved in its own cultural context and space. In places such as Antalya, where this tradition remains vibrant, the practice itself is realised with spaces called "canbazhane".

The Canbazhanes in question, where traditional circus arts are performed, have gained their cultural significance by being established during holidays, festivals, and fairs. These events meet the entertainment and aesthetic preferences of the people, bringing them together in a shared sense of excitement and unity. Through these practices, a distinct "Canbazhane Culture" has emerged within society, contributing to the preservation of this traditional art form.

Elmalı Abdal Musa Commemoration Events

Abdal Musa, also known as "Abdal Musa Sultan" in the region, was a Turkish saint of the 14th century whose tomb is located in the Tekke Neighborhood of Elmalı district. He was a prominent figure of the Hacı Bektaş-ı Veli Lodge and played a significant role in developing, institutionalising, and spreading the Alevi-Bektashi tradition. For this reason, he is regarded as the second pir (Piri Sani) of the Alevi-Bektashi tradition, following Hacı Bektaş Veli.

The Abdal Musa Tomb is a significant pilgrimage site in the Alevi-Bektashi tradition, and it is also visited and respected by individuals from the Sunni Islamic tradition. The "Abdal Musa Commemoration Ceremonies", held annually in the Tekke Neighborhood since 1983, have become a well-established tradition, fostering a spiritual atmosphere in the region. Organised under the leadership of the "Association for Research and Sustaining the Abdal Musa Culture", these events attract visitors from various countries and across the nation. Pilgrims visit the tomb to offer sacrifices, pray, and seek blessings.

Charity Pişi (fried dumpling) Tradition

Pişi, also known as "bişi", is a type of pastry made from yeast dough, typically fried in oil, with a characteristic hole in the middle, famous in the Antalya region. It is widely consumed in daily life and holds cultural significance as a ritual and special occasion food. Pişi is often prepared and served collectively during social gatherings and group meals, including military farewells, funerals, weddings, and circumcisions, particularly in the rural settlements of the province.

Pişi is an indispensable part of iftar and sahur meals during Ramadan. It is also prepared on special occasions such as Kandil, Kadir Night, Fridays, and Arafa and distributed to neighbours as charity. Offering pişi for charity is a common food ritual following a death, with the belief that the act's spiritual reward will benefit the deceased's soul.

Hıdırellez

Hıdırellez is a seasonal religious festival celebrated in recognition of the day when the Prophets Hızır and İlyas are believed to have met on earth. In Antalya, as in much of Türkiye, Hıdırellez is marked with various events and rituals associated with the awakening of nature. These practices are rooted in hopes for the coming year to bring abundance, prosperity, health, peace, and happiness. In preparation for Hıdırellez, homes are thoroughly cleaned. It is widely believed that Hızır will bring blessings and prosperity to the places he visits and the things he touches during the night of Hıdırellez.

Gılamık Weaving in Ormana District

Gılamık weaving is a traditional shuttle weaving technique still practised in the Ormana Neighborhood of İbradı. This type of weaving is also known by various names, including "Kılamuk", "gılamuk", "gılamıklı", "kılamuklu", and "gılamuklu", and is now commonly referred to as "Ormana Cloth" after the district it is most known. Gılamık weaving employs the bedding technique and was originally a form of silk weaving. However, due to the decline in silk production and challenges in marketing, cotton and linen threads are now also used. The weaving is done on wooden looms, locally called "düzen" or foot-operated looms. Historically, Gılamık products were primarily used as women's headscarves, a function that continues today. Additionally, the fabric is now utilised as decorative coverings for furniture, such as table and coffee table sets and bed sets.

Pıngıdık Game

The entire population of Gökbük Village is composed of Tahtacı Turkmens, with the village's settlement dating back to 1850. Oral accounts from the elderly suggest that the villagers initially coexisted with local Christians (referred to as Rum in Turkish) before becoming the sole inhabitants following the population exchange. The origins of the Tahtacı community in Gökbük can be traced to the Kumluca District of Antalya, though information regarding their earlier migration history is lacking. However, their history aligns with other Tahtacı communities in the mountainous coastal regions from Adana to Çanakkale.

One notable cultural element, the 'Pıngıdık Game,' has an uncertain origin. It is unclear whether it was brought by the Tahtacıs from their previous settlements or learned from the former Christian residents of the village. Oral traditions support the first possibility passed down through generations. Historically, Pıngıdık was played on March 21, marking Nevruz, which is also associated with the time of the highland migration. In recent years, the game has been played on a weekend in mid-February due to the emigration of the village's primary population and their return during the mid-term holiday. Nevertheless, it is important to note that the traditional timing of the game aligns with the celebration of Nevruz.

Project-specific Evaluation

The Yoruk culture is dominant in the Deniztepesi Neighborhood, where the Avşar Turks still reside. This community was formed by Yoruks who migrated from Central Asia and whose sanjak was Bozok Karahacılı. Aşure Day continues to be celebrated in the region, and there is also a rich wedding culture. Weddings typically begin with the arrival of the "aptal (fools)" on Fridays and continue throughout the weekend. Photographs of tangible and intangible cultural heritage interviews in different villages are shown in Figure XIII.66, Figure XIII.67, Figure XIII.68 and Figure XIII.69.

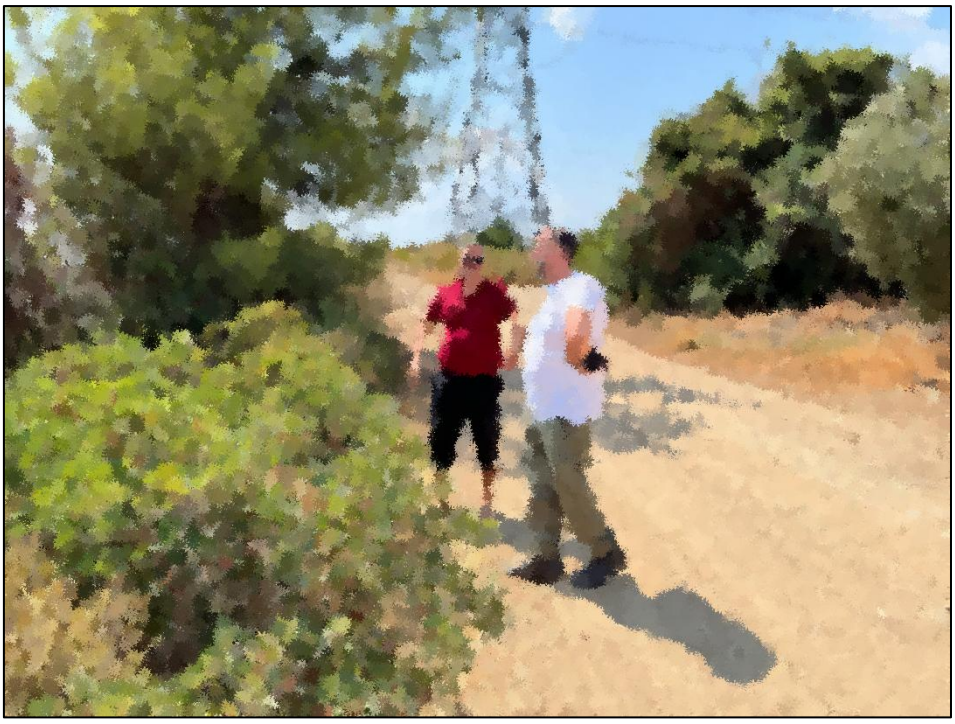

Figure XIII.66 Tangible and Intangible Cultural Heritage Interviews, Yavrudoğan Village

Figure XIII.67 Tangible and Intangible Cultural Heritage Interviews, Aksaz Village

In the interviews held in the Deniztepesi and Aksaz village, it was mentioned that Hıdırellez celebrations are still held in the village. Additionally, it was noted that during marriage ceremonies, the tradition of taking the bride from her house on a horse, as was customary in the past, is still practiced.

Figure XIII.68 Tangible and Intangible Cultural Heritage Interviews, Üründü Village

,

Figure XIII.69 Tangible and Intangible Cultural Heritage Interviews, Deniztepesi Village

According to the observations and research, the following inferences can be drawn:

- Local people depend on their traditions.
- Various festivals are held during the harvest season, depending on agricultural production.
- These festivals serve not only to promote the products obtained but also as opportunities for people to come together, socialize, and spend time with one another.
- Communities maintain their ethnic identities and continue to practice their traditions.
- No intangible cultural heritage elements have been identified in the immediate vicinity of the project site that will be negatively affected by the Project.

XIII.3.4. Palaeoanthropological and Paleontological Conditions

This section has been prepared to highlight the palaeoanthropological potential of caves and rock shelters in the province of Antalya and its surroundings dated to the Pleistocene–Early Holocene. It aims to summarise the evidence of human presence and behaviour—lithic technology, faunal remains, taphonomy and palaeoclimate—and, in the context of the project corridor, to produce a risk–sensitivity mapping to guide field investigations and conservation/monitoring measures.

Regional Framework

The coastal zone of Antalya and the foothills of the Taurus Mountains contain an extensive karstic cave system that offered favourable conditions for long-term human occupation. Key sites such as Karain, Öküzini, Beldibi and Belbaşı preserve rich cultural sequences spanning from the Middle–Upper Palaeolithic through the Epipalaeolithic and into the Neolithic transition.

Key Sites and Selected Findings

Karain Cave

One of Turkey's most comprehensive Pleistocene sequences, Karain Cave records a long history of occupation covering the Middle–Upper Palaeolithic. Small-mammal taphonomy and faunal assemblages have been used to reconstruct palaeoenvironmental conditions and predator activity. A 2024 study highlights the potential of speleothem (stalagmite) records from Karain for detailed palaeoclimatic reconstruction. In addition, the presence of Procaviidae (Hyracoidea) remains within Middle Pleistocene deposits provides significant evidence for biogeographical and palaeoclimatic interpretations.

Öküzini Cave

There is strong evidence of intermittent human occupation during the Late Pleistocene–Early Holocene. Systematic radiocarbon dating of its Epipalaeolithic sequence indicates a chronology from ca. 18,200 BC to ca. 6,600 BC. The lithic industries are characterised by backed microliths, lunates and triangles, alongside a diverse bone-tool repertoire. Faunal assemblages document changes in human–animal interactions and suggest a possible increase in plant exploitation.

Beldibi Rock Shelter

Upper Palaeolithic–Mesolithic lithic industries occur together with stylised rock paintings depicting motifs such as wild goats, deer and human figures. A multi-layered cultural sequence, up to six layers, has been reported.

Belbaşı Rock Shelter

Located approximately 5 km from Beldibi, Belbaşı preserves Late Palaeolithic/Mesolithic occupation; its location and stratigraphy have been described in detail in the classical literature[4].

Palaeontological Investigations along the Project Corridor

During the surface surveys, palaeontological findings were also included within the scope of the investigation. No fossilised marine remains or any stone tools were encountered during the investigations.

Based on the literature review, the information has been generally compiled from the articles and research notes of ***Işın Yalçınkaya, Mary C. Stiner, Steven L. Kuhn, F. Ocakoğlu, R. Lee Lyman, Şevket (Sevket) Sen, Gizem Kartal, Metin Kartal, Harun Taşkıran, İsmail Kılıç Kökten, Enver Yaşar Bostancı, and Dorothy A. E. Garrod****, accessible on the internet.*

XIII.4. Potential Impacts

This section identifies the potential impacts of the Project on cultural heritage during the land preparation, construction, and operation phases. The most significant impacts are expected to occur during the construction phase, due to extensive ground disturbance and vibration-generating activities.

The potential impacts on cultural heritage resources may be direct or indirect:

- Direct impacts are those resulting from physical disturbance within or immediately adjacent to a heritage site due to construction or land modification activities.

- Indirect impacts are secondary effects, including vibration, dust dispersion, restricted access, or changes to the visual and environmental context surrounding heritage sites.

During the construction phase phase, vibration arising from blasting and excavation activities may pose a risk to nearby cultural heritage assets, particularly to registered archaeological sites and vibration-sensitive structures. These aspects have been assessed in detail in accordance with the Project Standards for vibration-sensitive receptors.

There are no Indigenous Peoples recognized under national or international frameworks within Türkiye; therefore, no impacts related to spiritual or ceremonial heritage of indigenous peoples are anticipated.

On the other hand, the Project may also bring benefits if there are cultural heritage sites that were previously located in remote areas and could gain increased access through the operation of the Motorway. Also, through the baseline surveys and documentation of the previously unknown cultural heritage sites, the Project helps shed light on the still less known past of the region within the framework of interdisciplinary archaeological studies by implementing appropriate techniques and methods so that the Project, and contributes to the cultural and archaeological inventory of the country.

XIII.4.1. Land Preparation and Construction Phase

Impacts on Tangible Cultural Heritage

Impacts on cultural heritage may occur during the construction of the Project components, during which themaximum impacts are expected.

During the land preparation and construction phases, various project activities may generate direct and indirect impacts on tangible cultural heritage. These potential effects are summarized below .

Direct Impacts on Tangible Cultural Heritage

The potential direct impacts of the Project on cultural heritage assets may include the following:

- Physical disturbance or destruction of subsurface archaeological remains due to land clearing, excavation, or cut-and-fill operations.
- Loss or displacement of surface artifacts and cultural layers during topsoil stripping.
- Structural damage or destabilization of nearby archaeological features resulting from blasting and mechanical breaking.
- Partial removal or alteration of landscape features contributing to the integrity or visibility of heritage sites.
- Damage to architectural elements, walls, or burial features located within or adjacent to the working corridor.
- Accidental impacts from construction machinery, vehicle movement, or material stockpiling within or near sensitive areas.

- Ground compaction or surface abrasion leading to permanent modification of archaeological contexts.
- Disturbance or relocation of artifacts during the installation of temporary construction facilities, camps, or access routes.

As a result of the baseline surveys and subsequent assessments, the following **seven** archaeological sites located within the Project's cultural heritage impact area were identified as high-risk sites that will be subject to direct impacts of the Project:

- HRM 1- Cemeteries
- HRM 5- Cemeteries
- HRM 15- Cemeteries
- HRM 32- Church Remains
- HRM 37- Settlement
- HRM 42- Settlement

Among these sites, **cemetery areas and individual graves** are considered particularly sensitive cultural heritage features.

The measures to be taken to mitigate impacts on these sites (e.g. salvage excavation, documentation) are described in Section XIII.5, including a Grave Relocation Procedure for the management of impacts on cemeteries/graves.

Indirect Impacts on Tangible Cultural Heritage

The following **indirect impacts** may affect the cultural heritage resources during this phase of the Project:

- Vibration and ground movement from heavy machinery affecting the stability of nearby structures or ruins.
- Dust deposition and flyrock reducing the integrity or visibility of surface features.
- Visual intrusion and landscape alteration diminishing the historical setting or sense of place of heritage sites.
- Changes in natural drainage and micro-topography leading to erosion or sedimentation around archaeological areas.
- Restricted access to heritage sites used by local communities for traditional or religious purposes.
- Increased human activity and accessibility promoting unauthorized artifact collection or looting.
- Secondary degradation due to uncontrolled waste disposal, runoff, or poor housekeeping near heritage locations.

a) Blasting-Induced Indirect Impacts

During land preparation and construction, blasting activities are expected to generate ground vibration, air shock, and flyrock, as one of the main indirect Project impacts. These effects may pose direct risks to cultural heritage assets, such as structural stress, displacement of masonry, or dislodgement of fragile materials. In addition, indirect effects may occur through temporary air pressure waves (air shock) or the projection of rock fragments (flyrock), which could affect the physical integrity and setting of nearby archaeological sites within approximately 132.5 meters of the blasting locations.

The assessment of these potential impacts has been based on the vibration thresholds and modelling results presented in Chapter XI.2.3 (Noise and Vibration). Sensitive heritage receptors identified within the potential impact zone include HRM 5, HRM 6, HRM 8, HRM 9, HRM 16, HRM 20, HRM 38, HRM 41, HRM 45, HRM 50, HRM 51, HRM 52, HRM 53, HRM 57, and HRM 58. At these locations, the

proximity of heritage features to blasting operations increases the likelihood of cumulative vibration and air pressure effects.

Without mitigation, such effects could result in short-term, irreversible physical damage or partial loss of contextual integrity. The overall significance of these unmitigated impacts is assessed as moderate to high, depending on the receptor sensitivity and proximity.Relevant mitigation measures are presented in Section XIII.5.

b) Indirect Visual Impacts

Construction activities will be completed in 3 years thus the changes in the Project route due to construction activities will be relatively temporary in nature.

Impacts on Intangible Cultural Heritage

Assessment of the impact of the project on intangible cultural heritage has been conducted in the Project route and its vicinity in compliance with international standards and local legislation. No intangible cultural heritage elements have been identified in the immediate vicinity of the project site that will be negatively affected by the Project.

On the other hand, as discussed above, the Project activities are expected to physically affect the cemeteries. This may result in certain indirect impacts on intangible cultural heritage. The potential impacts are summarized below:

- Physical disturbance or damage to graves or associated structures from earthworks, heavy machinery, vibration, or accidental encroachment.
- Restricted or unsafe access for families and community members who visit graves for ceremonies or regular remembrance.
- Dust, noise and vibration creating nuisance or disrespect during ongoing burials or visits.
- Chance finds of previously unrecorded burials or archaeological remains requiring immediate protection and formal reporting.
- Social tension and reputational risk if communities perceive disrespect to burial grounds or if consultations are inadequate.

XIII.4.2. Operation Phase

During the operation phase, impacts may occur as a result of the presence and functioning of the permanent road infrastructure. These potential direct and indirect impacts on tangible and intangible cultural heritage are outlined below.

Impacts on Tangible Cultural Heritage

Direct Impacts

- Permanent modification of the landscape affecting the original topographic and contextual integrity of heritage sites.
- Structural stress or vibration from long-term traffic loads near sensitive archaeological remains.
- Limited risk of accidental damage during maintenance or utility works if conducted within heritage buffer zones.

Indirect Impacts

- Visual contrast between modern infrastructure and heritage landscapes, potentially reducing the aesthetic or symbolic value of sites.

- Increased accessibility leading to risks of vandalism, looting, or artifact collection by visitors or local communities.
- Indirect changes in surface water drainage or micro-climatic conditions affecting the conservation state of nearby remains.
- Potential reduction in the perception of heritage value due to the introduction of noise, lighting, and vehicle movement.
- Decreased community access to heritage locations if traffic or safety restrictions are imposed without alternative pathways.

Indirect Visual Impacts

In terms of visual impact, the changes along the Project alignment following the completion of construction activities will be of a permanent nature. The highway, viaducts, bridges, tunnel entrances, and lighting elements will become permanent components of the landscape, thereby affecting the visual integrity of the natural and cultural environment.

Accordingly, motorway itself and its large components such as viaducts, toll plazas, and service areas will be a source of change in the existing visual environment. Because of the experiential nature of visual resources, the human response to visual changes cannot be quantified, even though the visual changes associated with a development can be described.

These indirect impacts of the project occur in areas where structural remains are visible on the surface, relatively intact wall structures are preserved, and the project route remains within the visual impact zone.

These cultural heritage sites have been identified as HRM 6, HRM 29, HRM 41, HRM 48, HRM 49, HRM 50, HRM 53, HRM 54, HRM 55, and HRM 56. At these locations, there is no direct physical intervention on the cultural heritage assets; however, the visual alteration and perceptual integrity loss caused by the project corridor are considered indirect impacts.

In the visual impact studies, the designated cultural heritage sites were taken into account, and the visible and invisible areas of the road were mapped using ArcGIS. Cultural heritage sites were categorized into three categories based on their visibility from the road: fully visible, partially visible, and invisible. All visibility maps identified the category as partially visible.

Maps of the Project route, where cultural heritage sites are partially visible are presented between Figure XIII.70 and Figure XIII.79.

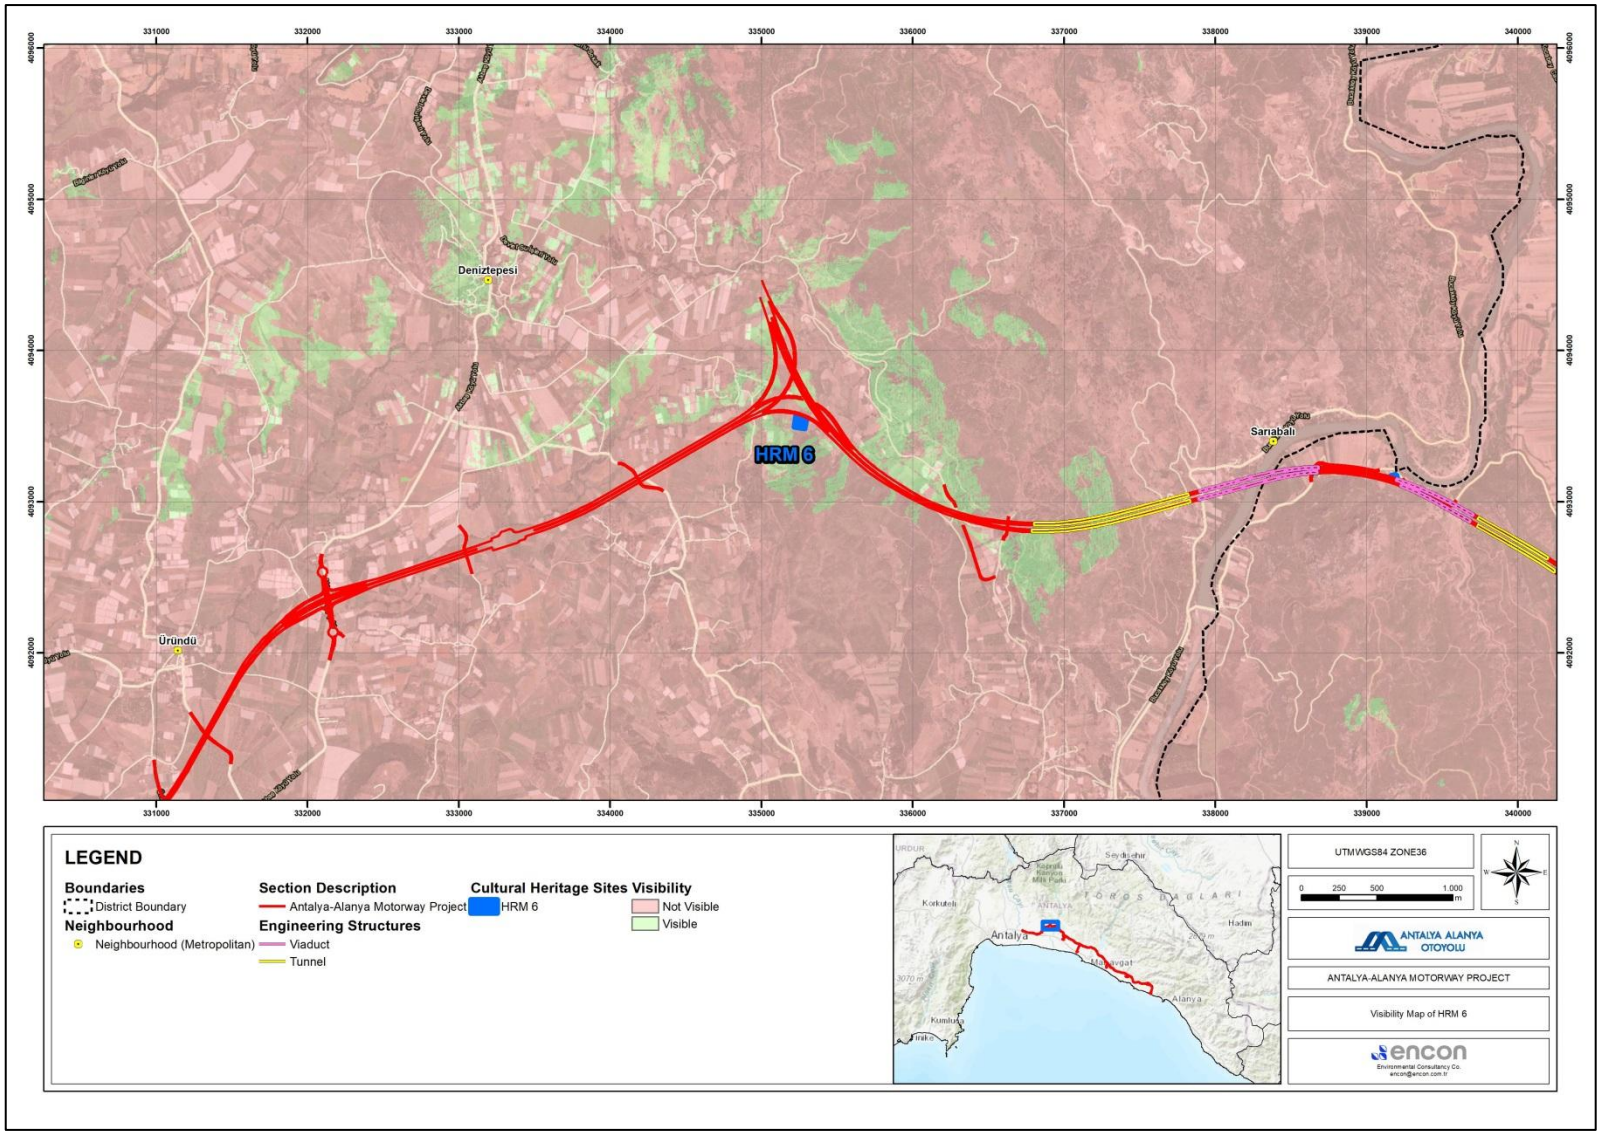

Figure XIII.70. Visibility Map of HRM 6

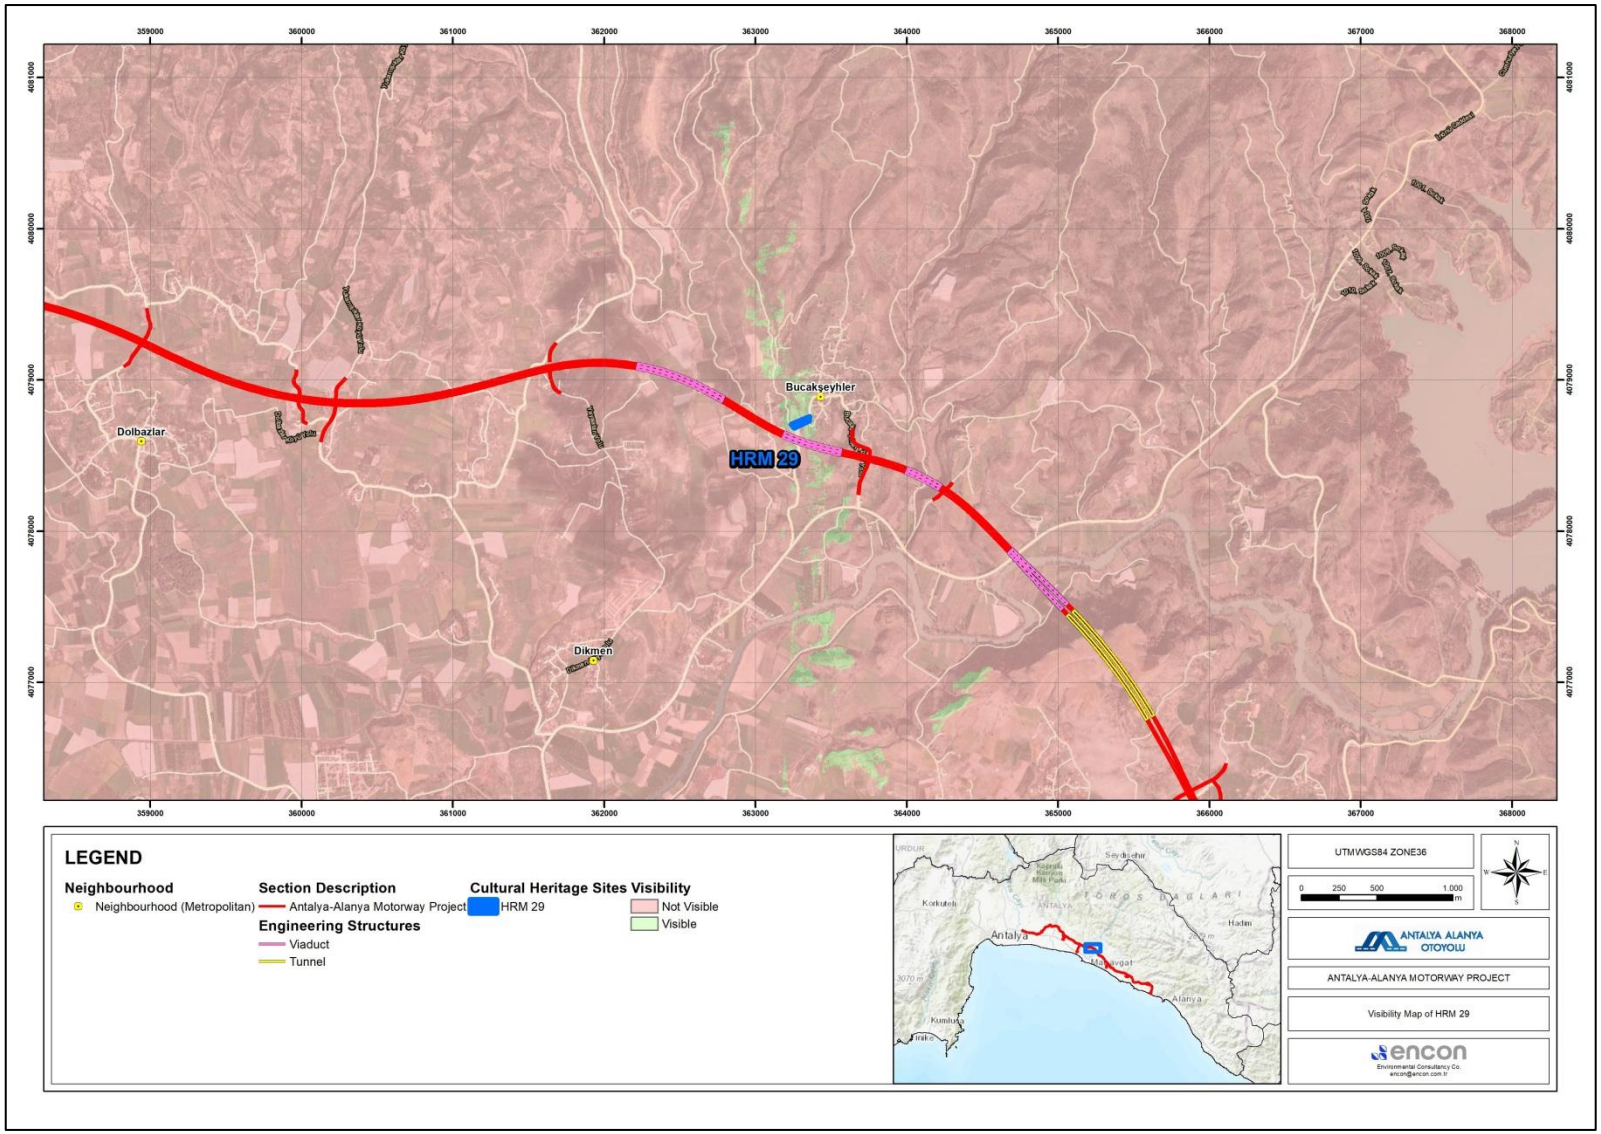

Figure XIII.71. Visibility Map of HRM 29

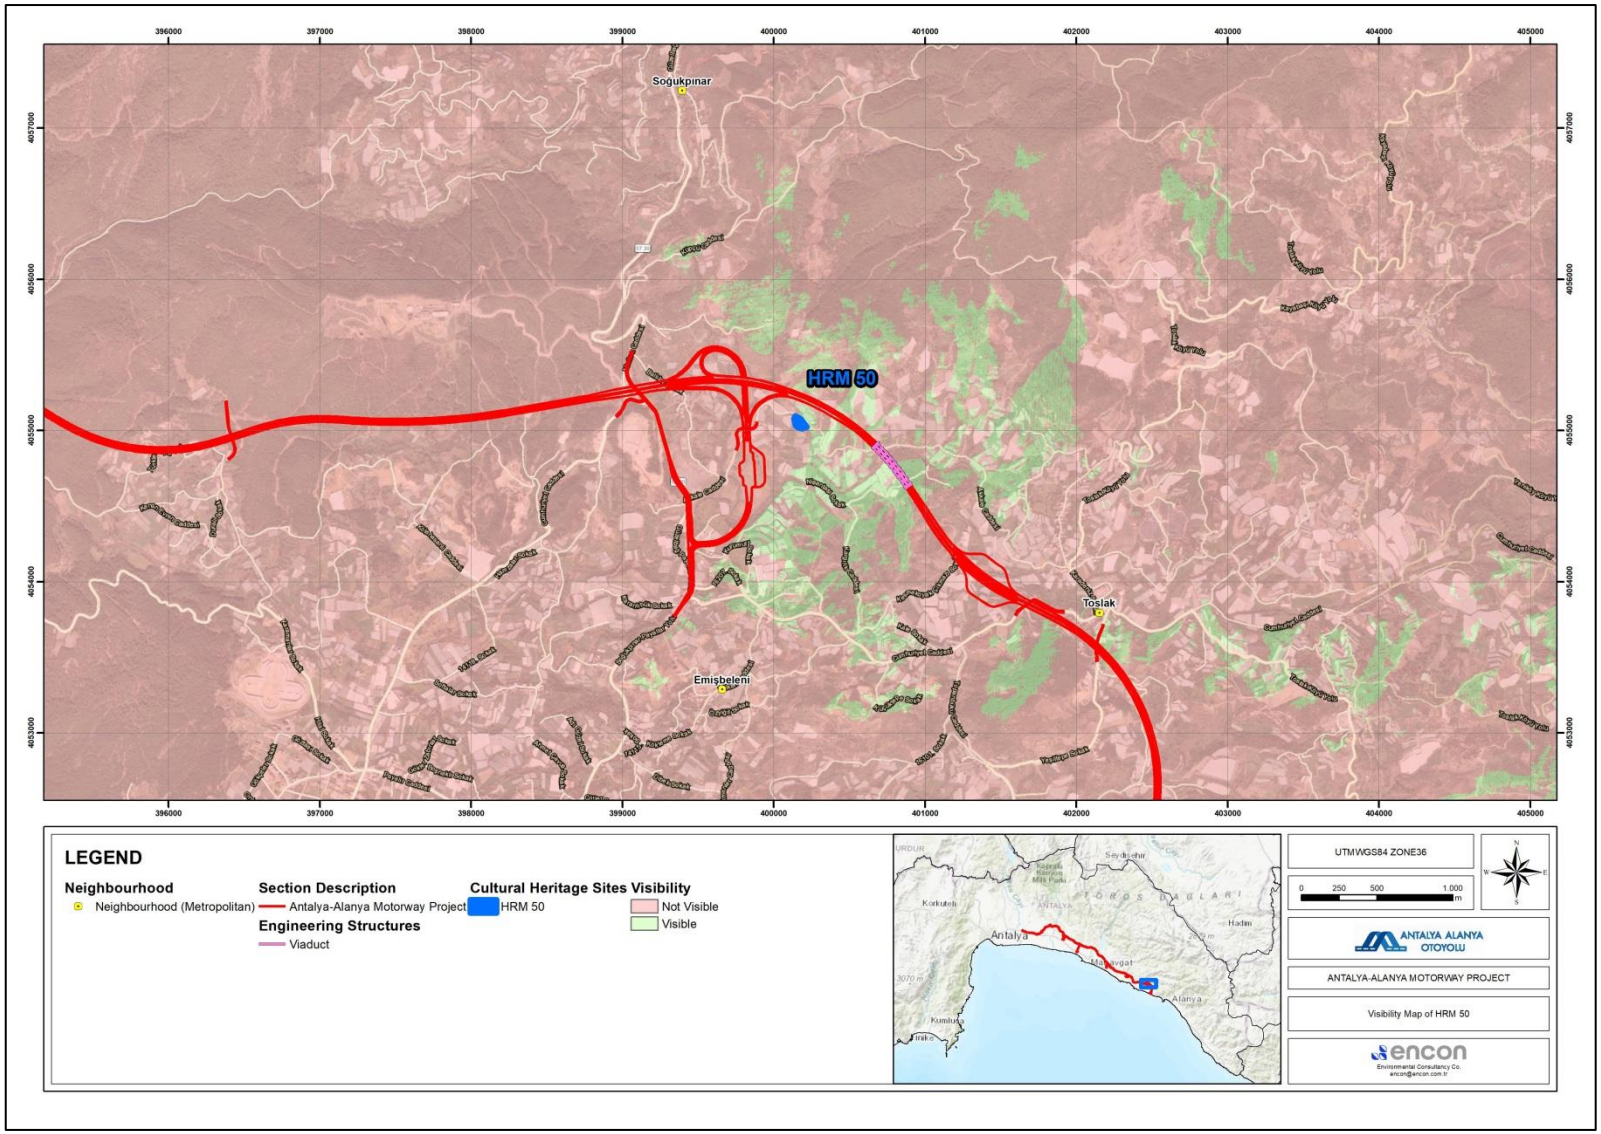

Figure XIII.75. Visibility Map of HRM 50

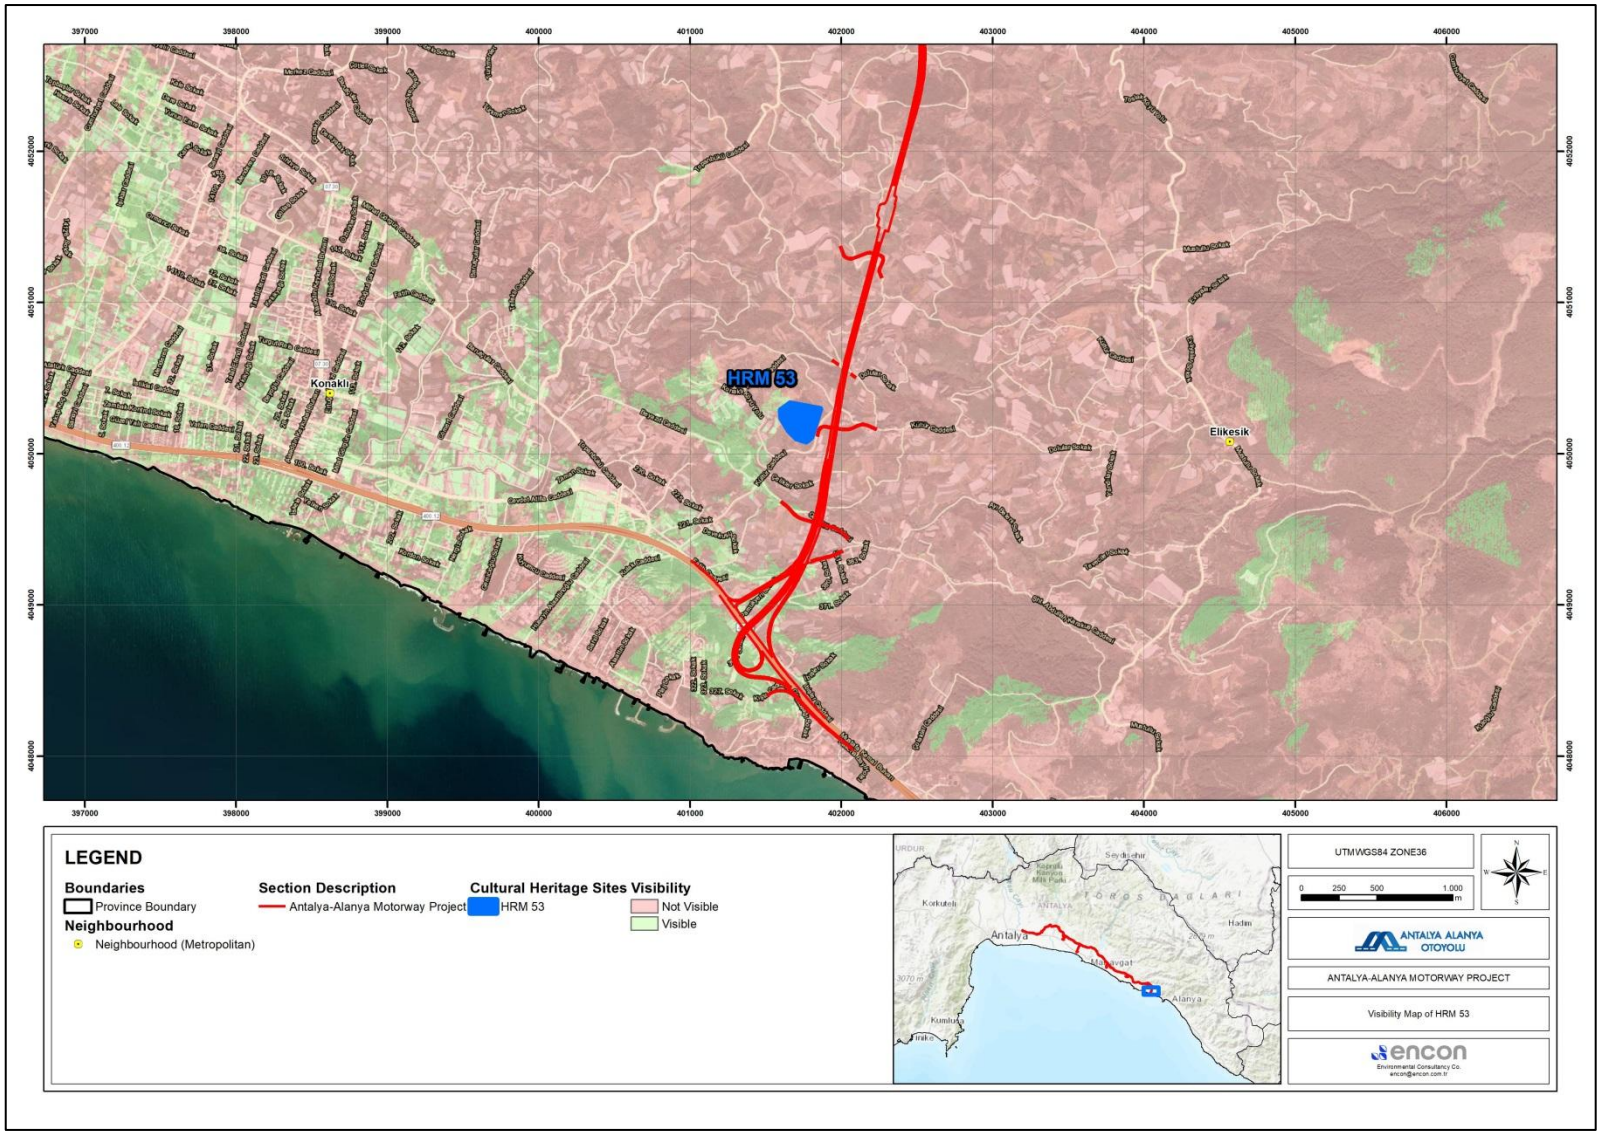

Figure XIII.76. Visibility Map of HRM 53

Figure XIII.77. Visibility Map of HRM 54

Figure XIII.78. Visibility Map of HRM 55

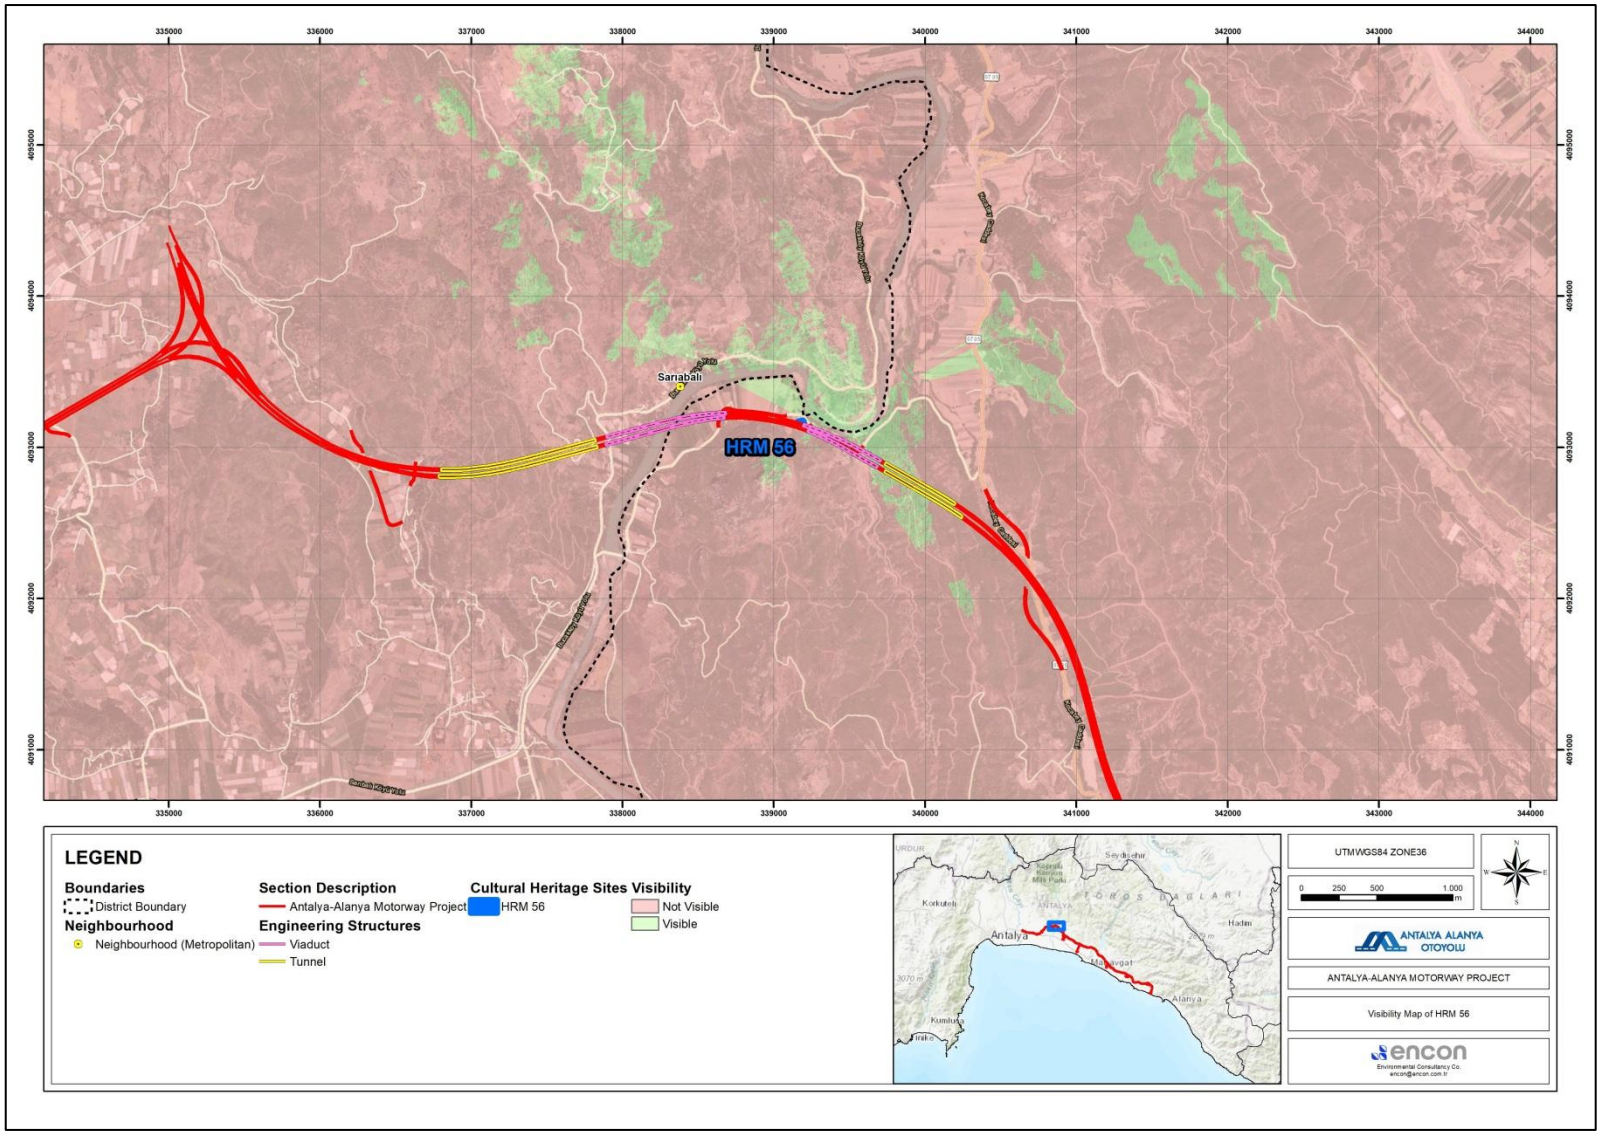

Figure XIII.79. Visibility Map of HRM 56

Impacts on Intangible Cultural Heritage

During the Project operation phase, impacts on cemeteries may lead to indirect impacts on intangible cultural heritage. While direct physical impacts associated with construction are no longer relevant, some impacts are important to consider. These impacts are listed below:

- Ongoing community access conflicts if operational security or fencing restricts traditional visits and ceremonies.
- Long-term noise, traffic or pollution affecting the sanctity of the cemetery or creating a sense of disrespect.
- Erosion or indirect impacts (e.g., water runoff, vibration from ongoing operations) that could damage grave structures.
- Loss of intangible cultural heritage if traditional rituals or periodic festivals linked to the cemetery are disrupted.

XIII.4.3. Decommissioning and Closure Phase

The impacts during the decommissioning phase are likely to be similar to those of the construction phase; hence, the activities will be identical to those of the construction phase. The route is expected to be restored to its previous use.

XIII.4.4. Assesment of Impact Significance

The significance of potential impacts on cultural heritage assets has been assessed in accordance with the methodology described in Section XIII.1.2.3, which follows both the ICOMOS Guidance on Heritage Impact Assessments for Cultural World Heritage Properties (2011) and IFC PS8.

The evaluation combines the heritage value (sensitivity) of each asset and the scale and severity of change/impact (magnitude) predicted to result from Project activities. This approach ensures consistency with both national procedures recommended by the Ministry of Culture and Tourism and international best practice.

The results of this assessment are summarized in Table XIII-14 – Impact Register Table, which presents for each HRM the significance of impact based on the baseline value of the heritage assets and predicted magnitude of impact, as well as the proposed mitigation, and residual significance after mitigation.

XIII.5. Mitigation and Management Measures

Mitigation measures will be taken for the sites identified during the ESIA studies in order to avoid and/or minimize the adverse impacts of the Project on those sites. All site-specific mitigation and management measures have been developed and implemented in close consultation with the Antalya Regional Directorate for the Protection of Cultural Heritage (ARHB) to ensure full compliance with Law No. 2863 on the Protection of Cultural and Natural Assets (1983) and other applicable Turkish legislation.

In addition, the mitigation framework has been structured in alignment with the IFC PS 8 (Cultural Heritage) and the IFC mitigation hierarchy, which together provide internationally recognized best practices for cultural heritage protection. This dual compliance ensures that both national legislative requirements and international standards are met, while safeguarding tangible and intangible cultural heritage values.

Mitigation follows the principles of the IFC Mitigation Hierarchy:

- ***Avoidance:*** In all instances, avoidance must be the preferred measure. During the Project design and planning process, several archaeological areas identified through baseline surveys were excluded from the Project footprint. Realignment and design modifications were applied to ensure that critical or non-replicable sites were not affected.

- ***Minimisation:*** Where complete avoidance was not feasible, impacts were reduced through protective buffer zones, restricted access, and adapted construction methods. For example, minor design changes were implemented in areas close to archaeological sites to reduce potential impacts.

- ***Restoration / Conservation:*** Where impacts occurred or risks were identified, restoration and conservation works were carried out under the authority of the Museum Directorate and in accordance with ARHB decisions.

- ***Offset / Compensation:*** No offset measures have been required to date, as avoidance and minimisation strategies have effectively addressed the identified risks. However, if needed, offset measures (e.g., enhanced conservation, awareness activities, or public access to alternative heritage resources) may be considered.

In this respect, the mitigation strategy of the Project has been established according to IFC Heritage Value Categories, as summarized in Table XIII-9.

Table XIII-9 Mitigation Strategy according to IFC Heritage Value Categories

Category	Brief Description	Relevance for the Mitigation Hierarchy
Non-replicable	Cultural heritage assets that cannot be replaced or reproduced; their loss cannot be recovered (e.g., archaeological sites, unique ritual areas).	Priority: full avoidance. Relocation or offsetting is not acceptable.
Replicable	Heritage that can be reconstructed elsewhere or relocated after thorough documentation while preserving its essence (e.g., movable architectural elements).	Priority: avoid where possible; if unavoidable, controlled relocation/reconstruction.
Critical Cultural Heritage	Heritage of outstanding significance, nationally or internationally recognised; typically also falls under “non-replicable”.	Avoidance plus international best practice and continuous stakeholder engagement.

Sites or formations identified as potentially significant in terms of **palaeoanthropology and paleontology** will be managed under the Chance Find Procedure and the Cultural Heritage Management Plan (CHMP) to ensure appropriate protection and reporting.

XIII.5.1. Management of Impacts on Tangible Cultural Heritage

In accordance with the IFC PS 8 and the general principles of mitigation hierarchy, , multiple sections of the route have been revised due to the presence of archaeological assets identified in the field. Accordingly, the Project design team has implemented changes and partial revisions in 15 archaeological locations, thereby avoiding potential adverse impacts on the identified heritage assets. These sites that have been avoided through design changes are listed in Table XIII 10.

Table XIII-10 Cultural Heritage Avoided by Route Change or Design Change

HRM ID	Type	Period	Location	Registration Status

HRM 60	Settlement or Necropolis	Roman / Byzantium	Located along the D-400 Highway and near the Taşağıl Access Road Antalya / Manavgat Taşağıl	1st Degree

Mitigation measures and recommended actions have been developed for each identified **tangible** cultural heritage asset to prevent, minimize, or manage potential adverse impacts. These measures will be implemented in parallel with the general mitigation principles outlined below, which apply to all Project activities that may affect cultural heritage during the land preparation, construction, and operation phases.

- Archaeological immovable assets that are located on the Project Route and its area of influence may be buried or covered entirely with vegetation. For this reason, during the deforestation activities on the Project Site, the Client will conduct a visual inspection. The construction activities are carried out under the supervision of an archaeologist. Additionally, all archaeological findings will be recorded on the Project's constraint maps, and protective measures will be implemented by placing "Critical Area" warning signs in the vicinity of the archaeological site.In compliance with laws no: 5226 and 3386 and the 4th article of the revised law no: 2863, in case any movable-immovable cultural asset is encountered as a result of the activities conducted during the field preparation and construction stages, the activities should be stopped, and Directorate of the Antalya Archaeology Museum should be notified immediately.
- The Cultural Heritage Management Plan and Chance Find Procedure required for the management of "chance finds" have been prepared and submitted as an annex to the Cultural Heritage Management Plan. All operators who are to be engaged in the soil works and Project employees will receive training regarding "project requirements, protection of cultural and archaeological heritage, laws and legislations related with the archaeological and cultural heritage and cultural heritage management plan and chance find procedures".
- Chance Finds Procedure will be implemented by trained construction workforce to avoid or minimize significant impacts. Accordingly, in cases when a chance find is encountered

during the construction activities, further steps will be taken in accordance with the plans and procedures and the relevant bodies, and the Directorate of the Museum should be notified immediately. If any archaeologically potential asset is discovered, relevant instructions about the site's sensitivity will be shared with all construction teams a few days before the construction activities. The construction activities will be conducted using appropriate equipment and methods. The proper equipment will be identified together with the directorate of the museum and the construction teams.

- In areas where there is an identified or potential archaeological risk, archaeological excavations will be carried out and completed prior to the commencement of construction. In addition, all required documentation must be fully prepared and submitted to the relevant authorities as part of the permitting process before any excavation activities begin.
- Archaeological areas will be notified to the relevant museum directorates immediately.
- Considering the assessments provided in Chapter XI.2.3 (see Table XI.36), which covers vibration impact assessment, the quantities of explosives will be optimized in areas near archaeological sites. During pre-construction surveys, the impact of construction activities on cultural heritage aspects will be considered, and vibration measurements will be repeated in areas deemed necessary. Vibration calculations will be updated to ensure that no damage will be caused to the archaeological heritage before construction begins. Additionally, If the specialized contractor determines that the required charge quantity is too low to be effective, mechanical breaking methods may be employed as a precautionary measure to safeguard these areas.

For the **seven** high-risk archaeological sites identified in Section XIII.4.1 (HRM 1- Cemeteries; HRM 5- Cemeteries; HRM 15- Cemeteries; HRM 32- Church Remains; HRM 37- Settlement; HRM 42- Settlement), project works will not commence until all permits are obtained from the relevant authorities (i.e. ARHB) and required archaeological works, including surveys, archaeological trial excavation, salvage excavations, documentation, etc., have been completed.

The current status of work to be carried out in high-risk archaeological sites is presented in **Error! R eference source not found.**. These measures constitute pre-construction mitigation commitments to ensure cultural heritage protection.

Table XIII-11 Table of High-Risk Archaeological Areas

Type	Status – Contractor Procurement	Planned / Ongoing Activities
HRM 1- Cemeteries	ARHB permitting process is ongoing. The finalization of the design is awaited. Excavation of approximately 10 modern and historic graves is planned under the supervision of the Museum Directorate. The graves are planned to be relocated within the boundaries of the same cemetery. The specific relocation site will be determined by the Metropolitan Municipality Cemeteries Directorate.	Excavations are scheduled to commence as of Q4, 2025.
HRM 5- Cemeteries	ARHB permitting process is ongoing. The design has been finalized. The presence of the Museum Directorate specialist is awaited, and under the supervision of the specialist, the excavation of approximately 40 graves is planned. Since the area is not registered at this stage, it cannot be confirmed whether the graves are of historical character; the outcome of the excavation is awaited. However, the Board has indicated that in either case, the graves may be relocated. The graves are planned to be relocated within the boundaries of the same cemetery. The specific relocation site will be determined by the Metropolitan Municipality Cemeteries Directorate.	Excavations are scheduled to commence as of Q4, 2025.
HRM 15- Cemeteries	ARHB permitting process is ongoing. The design has been finalized. Under the supervision of a Museum specialist, the excavation of approximately 25 graves is planned. Modern graves are also present within	Excavations are scheduled to commence as of Q4, 2025.

Type	Status – Contractor Procurement	Planned / Ongoing Activities
	the cemetery. The Board has indicated that in either case, the graves may be relocated. The graves are planned to be relocated within the boundaries of the same cemetery. The specific relocation site will be determined by the Metropolitan Municipality Cemeteries Directorate	
HRM 32- Church Remains	ARHB permitting process is ongoing. Archaeological excavation works are ongoing. The site, located within the expropriation corridor but outside the active construction footprint, will be relocated and exhibited in a designated safe area to ensure its protection and continued visibility. The official coordination process between the Antalya Regional Board for the Protection of Cultural Heritage (ARHB), the General Directorate of Highways (KGM), and the Project Sponsor is ongoing to determine the final relocation site.	The completion of the excavations and the relocation and reconstruction of the structure are scheduled for Q2/Q3 2026.
HRM 37- Settlement	ARHB permitting process is ongoing. An application has been submitted to the Antalya Regional Board for the Protection of Cultural Heritage (ARHB) regarding this area. Following the route revision, the alignment has been shifted outside the boundaries of the 1st-degree archaeological site. However, since no design revision could be implemented within the 3rd-degree registered area, a test trench excavation was requested in accordance with the applicable legislation and will be carried out under the supervision of the Antalya Museum Directorate.	Excavations are scheduled to commence as of Q4, 2025.
HRM 42- Settlement	ARHB permitting process is ongoing. Vegetation clearance has been completed, the excavation contractor has been appointed, and trial trenches will be opened under the supervision of the Museum Directorate.	Excavations are scheduled to commence as of Q4, 2025.

Main aims of the mitigation measures regarding visual impacts are

Management of Blasting Impacts

To address blasting-induced risks and impacts, site-specific mitigation and monitoring measures have been developed in coordination with the Noise and Vibration assessment and are detailed in Table XIII.12 (Blasting-Induced Impact Mitigation and Monitoring Measures). These measures ensure that all potential effects—including ground vibration, air shock, and flyrock—are managed within acceptable thresholds and in compliance with the requirements of the ARHB and the Museum Directorate.

To manage and minimize potential impacts from blasting—including vibration, air shock, and flyrock—site-specific mitigation measures have been developed for each identified HRM location (see Table XIII.11). These include:

- Optimization of the charge per delay and use of delayed blasting;
- Application of protective blasting mats or coverings to prevent flyrock and reduce air shock;
- Real-time vibration monitoring near sensitive receptors;
- Coordination with the Antalya Regional Conservation Council (RCHB) and Museum Directorate prior to each blast;
- Suspension of blasting when exceedance risk is identified;
- Implementation of archaeological supervision and buffer zones at active work fronts.

The implementation of these measures will ensure that ground vibration, air shock, and flyrock remain within the safe threshold limits defined in Chapter XI.2.3, and no adverse effects are expected on cultural heritage receptors. Therefore, when properly applied, these mitigation actions are expected to prevent the occurrence of significant vibration-, air shock-, or flyrock-related impacts.

Table XIII-12 Site-Specific Vibration Measures for Cultural Heritage

Site	Explanation	Mitigations	Residual Impact	Monitoring
HRM 5	For HRM 5, salvage excavation is underway, with construction paused until the salvage excavation is finished. Construction activities will only proceed once the archaeological excavation has been fully completed and the necessary approvals have been obtained from the Board, the Municipality, and the Republic of Türkiye Ministry of Environment, Urbanization and Climate Change. Upon permit approval, minimal explosive charges will be used to prevent damage to the site.	Wait until the excavation is finished	Change of location of the site; minumum impact on archaeological site	Archaeological surveys coordinated with the Museum Directorate.
HRM 6	Remains of an architectural structure, possibly from the Roman Period, likely representing a frontier garrison settlement. A dense accumulation of rubble stone and visible wall rows, which may belong to the structure, are present on the surface. Additionally, numerous roof tile fragments and a small number of sherds from daily use vessels have been observed.	No blasting will be carried out before the decision of the conservation board. After the decision, a control survey/drilling operation will be done on the area. The measures determined by the Board will be implemented based on the results of the survey.	-No impact on archaeological site	-
HRM 8	This area is a natural protected zone. Therefore, throughout the entire process, we will reduce the maximum charge per delay (kg) and conduct survey and monitoring activities through an external contractor.	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be placed at 53 m, with weekly ecological surveys and compliance reporting to the Ministry of Environment.
HRM 9	HRM 9 has not been registered by the Board (Permitting date and No.: 26.12.24/18914) and a construction permit has been granted for working on this area. But in case of Chance Find during the construction, Article 4 of Law No. 2863, the work is to be halted, and the Museum Directorate must be notified.	Visual inspections for chance find will be implemented. In accordance with Article 4 of Law No. 2863, if any archaeological remains are encountered during construction, all activities must be halted immediately and the Museum Directorate must be notified.	Negligible risk unless chance finds occur.	An on-site archaeological observer will monitor works, with immediate halting and notification to the Museum Directorate in case of chance finds (Law No. 2863).
HRM 16	Lowering the maximum Charge per Delay (kg).	For HRM 16, at 60 meters, the maximum charge per delay (kg) will be reduced. Use a charge of 2.2 kg with electronic detonators will be applied.	PPV: 4.968 mm/s. Low risk or negligible, but nearing threshold. Monitoring recommended during blasting.	Seismographs will be positioned at 60 m, and a pre-blast structural stability survey will be conducted.

Site	Explanation	Mitigations	Residual Impact	Monitoring
HRM 20	HRM 20 is a 1st degree archaeological site. This area is not located on the project route, but is located within the Dikmen Quarry. The HRM-20 registered archaeological site is an aqueduct that supplied water to the ancient city of Side. Because the area has been designated a first-degree archaeological site, the opinion of the Antalya Board will be sought before any activity begins. Additionally, a 100-meter buffer zone will be established between the blasting area and the archaeological site to provide protection, and no activity will be carried out within this zone.	a 100-meter buffer zone will be established between the blasting location and the archaeological site to provide protection, and no activity will be carried out within this zone. The opinion of the Antalya Board will be sought before any activity begins. A charge of 6.15 kg using electronic detonators will be employed. A 100 m buffer zone from the ancient waterway must be maintained. The site is currently on standby. If the appointed specialist contractor determines that blasting is not a viable option, mechanical breaking may be used as an alternative.	PPV: 4.968 mm/s. Low risk or negligible, but nearing threshold. Monitoring recommended during blasting.	Seismographs will be positioned at 100 m, and a pre-blast structural stability survey will be conducted.
HRM 38	The archaeological site lies at the summit of the hill, whereas the designated blasting area is located along the foothill. Given the topographical separation and distance, vibrations are expected to be attenuated. Furthermore, the recent design change led to the determination of the work area by the shoring (IKSA) wall, which established a clear boundary. Within this defined area, preventive measures can be implemented using a small amount of explosives or through mechanical breaking methods to minimize any potential impact as explained in the above paragraphs.	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs. A shoring (IKSA) wall will be installed to minimize vibration, and stemming applied to limit air overpressure near the site. Based on the external contractor the charge can be modified based on the attenuation.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be placed at 15 m and behind the IKSA wall, with structural surveys of the hill summit before and after blasting.
HRM 41	Lowering the maximum Charge per Delay (kg).	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be installed at 20 m to monitor vibration attenuation over distance.

Site	Explanation	Mitigations	Residual Impact	Monitoring
HRM 45	Lowering the maximum Charge per Delay (kg.	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be installed at 30 m to verify compliance with PPV limits.
HRM 50	Lowering the maximum Charge per Delay (kg).	Use a charge of 3 kg with electronic detonators.	PPV: 4.975 mm/s. Low or negligible risk, but nearing threshold. Monitoring recommended during blasting.	Seismographs at 70 m to monitor vibration attenuation over distance. Pre-blast survey.
HRM 51	Lowering the maximum Charge per Delay (kg).	Use a charge of 6.15 kg with electronic detonators.	PPV: 4.993 mm/s. Low or negligible risk, but nearing threshold. Monitoring recommended during blasting.	Seismographs at 100 m to monitor vibration attenuation over distance.
HRM 52	Lowering the maximum Charge per Delay (kg).	Use a charge of 6.92 kg with electronic detonators.	PPV: 4.999 mm/s. Low risk or negligible, but nearing threshold. Monitoring recommended during blasting.	Seismographs will be installed at 106 m to monitor vibration attenuation over distance.
HRM 53	Lowering the maximum Charge per Delay (kg).	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs .	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs at 29 m to monitor vibration attenuation over distance.
HRM 57	With the design change, the route was moved outside the archaeological site, reducing potential impacts. A preliminary survey will be done to assess the situation, and measures like reducing explosives use will be applied.	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible..	Seismographs will be placed at 10 m, with archaeological monitoring to ensure protection of heritage assets.

Site	Explanation	Mitigations	Residual Impact	Monitoring
HRM 58	With the design change, the route was moved outside the archaeological site, reducing potential impacts. A preliminary survey will be done to assess the situation, and measures like reducing explosives use will be applied.	A minimum charge of 2 kg for 3 m hole (as common practice) will be used at distances of 56.96 meters or more, establishing a conservative baseline for safe blasting near sensitive archaeological features. Within 56.96 meters, no blasting will occur; instead, mechanical breaking with excavators will be employed as explained in the above paragraphs.	With these measures, any impact on sensitive archaeological features is expected to be minimal or negligible.	Seismographs will be placed at 10 m, with archaeological monitoring to ensure protection of heritage assets.

In the Table XIII-11, these measures ensure compliance with established ground vibration thresholds, 15 mm/s at 66.8 m and 8 mm/s at 98.4 m for quarries, and 10 mm/s at 86 m and 5 mm/s at 132.5 m for tunnels and cut-and-formation works, while protecting cultural heritage and nearby settlements. A minimum charge of 2 kg for 3 m hole (as common practice) (ANFO powder + dynamite) produces a peak particle velocity of 5 mm/s at a distance of 56.96 meters, establishing a conservative baseline for safe blasting near sensitive archaeological features. No blasting will be conducted within 56.96 meters; mechanical breaker's vibrations are not expected to affect the cultural heritage sites except for HRM 6 which is still being processed by the board.

Management of Visual Impacts

During the period of construction, following measures will be taken to migitage the indirect **visual impacts** with an objective of keeping the changes as small as possible and limiting the visibility of the adverse changes while ensuring the design and construction of the project in a manner that the project melts into the landscape:

- Existing vegetation to be protected will be fenced with temporary protective fencing before work commences on site, so that as much vegetation as possible could be protected to maintain the integrity of the landscape and the existing visual screening.
- Working areas will be kept as small as practicable. Visual barriers will be implemented if the area is subjected to high visual impacts.
- The construction sites will be kept tidy and workers will have necessary knowledge/training about the issue.
- Temporary fencing will be implemented to obstruct intense construction activity areas.
- Implementation of landscape design along the road using vegetation compatible with the natural environment.
- Planting of appropriate tree and shrub species to create visual barriers.
- Establishment of green strips to reduce visual interaction between the project corridor and cultural heritage sites.

XIII.5.2. Management of Impacts on Intangible Cultural Heritage

Baseline information on **intangible** cultural heritage is provided in Section XIII.3.3.

During the **construction phase**, the following measures will be implemented along with the general mitigation measures given below:

- • Clearly demarcated buffer zones will be established and maintained around all designated cemeteries, prohibiting the entry of equipment except under approved procedures. vibration, dust and noise control measures will be implemented (e.g., low-vibration equipment, water spraying, acoustic barriers).
- Safe and uninterrupted access routes for relatives and community members will be provided, with signage and alternative pathways arranged where necessary.A formal Chance Find Procedure (CFP) will be applied in accordance with IFC PS8 and national law, ensuring immediate work stoppage, notification of the Museum/Heritage Authority, and written clearance prior to resuming work..
- In the pre-construction period, meetings will be held with the mukhtars. Dates of the activities, rituals, etc., for local days or more extended activity periods planned to be held in the region will be learned through meetings with the mukhtars and local people. The community will be prevented from being affected by the construction in possible customary practices that can be experienced locally.
- Mobility of the people and vehicles during the activities planned to be held in the region will not be prevented,
- Contractors and subcontractors will be trained on the code of conduct, including their approach to relations with local communities, during the employment phase and at regular intervals throughout the Project.
- Information regarding intangible cultural heritage will be provided to contractors and subcontractors on any site-specific sensitivity/issue (e.g., festival locations, dates, events, etc.).

Although no specific ICH elements within the immediate Project footprint are expected to be adversely affected, the SPV will continue engagement with the households in affected settlements to document potential ICH aspects that may not have been captured during the baseline assessments, ensuring

continued sensitivity to community traditions. Engagement and site observations will be conducted particularly in districts, villages, and neighbourhoods where cemetery areas are located. This work will proceed under the oversight and coordination of the Project Archaeologist and the Project CLOs. A review of Chapter XIII indicates that the ICH-related locations primarily comprise areas where the public congregates or performs religious rites—such as cemeteries—and that several such locations are affected by the Project, with some graves requiring relocation. Measures to be takend during grave relocation are separately addressed under Section XIII.5.3.

Mitigation measures and recommended actions identified during the **operational phase** for intangible cultural assets are given below:

- Permanent, sign-posted access routes will be maintained, and visiting hours or access arrangements agreed with the community shall be clearly communicated.Long-term environmental controls, such as dust suppression, traffic management, and drainage and erosion control, will be implemented to prevent gradual physical damage.
- Periodic community consultations will continue to identify evolving cultural needs and assess the effectiveness of mitigation measures.Cemetery-related cultural events and visiting patterns will be integrated into the site's operational management plan to ensure that ceremonies and rituals are not disrupted..

XIII.5.3. Grave Relocation Procedure

Baseline archaeological surveys also identified a number of cemetery areas, some of which have been formally registered and legally protected, while others continue to be used for modern burials. These sites therefore embody both historic graves and contemporary burial practices, attracting regular visits from families and community members. This dual character means that, alongside tangible heritage protection, the Project will also address the intangible heritage dimension associated with ongoing rituals and commemorative practices.

The relocation of graves is a highly sensitive process and will be implemented in line with national legal requirements and local practices. In all cemetery areas, where the alignment cannot be modified or where cemeteries are encountered incidentally, and in cases where modern-era cemeteries are affected by construction, Whenever work is required in any such area, the identified graves will be first reported by the SPV to KGM, and KGM will them **notify** the relevant public authorities, as detailed below. If graves identified during the archaeological baseline study are determined to be of **historical significance**, first the Regional Conservation Board will be notified. Through the Board's process, if the graves are confirmed to have **historical value**, the registration procedure will first be completed before relocation.

Grave relocation activities will be undertaken under the supervision of the Antalya Museum Directorate and ARHB, in accordance with relevant national legislation and IFC PS 8 requirements. This will include consultations with the relevant local authorities (the Municipality; the Ministry of Environment, Urbanization and Climate Change / Directorate of Local Administrations; the Directorate of Cemeteries). Official letters will be submitted to these entities; notices regarding the planned works in villages will be

posted; the public posting period will be monitored; and one-to-one meetings will be held with grave owners to obtain signed consent forms.

To manage these combined responsibilities, the Project will:

- Engage with stakeholders and communities through regular, documented consultations with families and local religious/community leaders, provide advance notice of planned works and agree on temporary access routes for visitors.
- Maintain access and demonstrate respect, ensuring uninterrupted and dignified access for relatives and visitors, establishing clearly marked buffer zones and, where necessary, applying quiet hours during ceremonies.
- Protect archaeological and heritage values by demarcating and fencing historic and modern graves separately, and implementing vibration, dust and noise controls during construction works near cemeteries.
- Implement Chance Find and monitoring procedures, including a formal Chance Find Procedure for any unexpected discoveries and continuous archaeological monitoring in high-risk areas.

Prior to construction, meetings will be held with village/neighbourhood headmen (muhtars) and the outcomes will be recorded. During the construction phase, potential construction-related issues will be identified through these meetings and the corresponding needs will be listed. As an initial action, during the muhtar meetings, communities will be informed to ensure that no difficulties are encountered regarding access to cemeteries; in addition to other potential complaints, it will be reiterated that complaints related to ICH can also be submitted through the established Grievance Redress Mechanism (GRM).

Through these measures, the Project will safeguard both tangible and intangible cultural heritage, protect legally registered cemeteries, respect ongoing burial traditions, and maintain full compliance with Turkish legal requirements and international standards such as IFC PS5 & PS8, World Bank ESS8, EBRD PR8 and ICCROM guidelines.

This matter will be monitored by the Project Archaeologist and the CLO team and will be reported regularly in the monthly reports.

This issue, detailed in the Stakeholder Engagement Plan, will be monitored by the Project Archaeologist and the CLO team and will be reported regularly in monthly reports (see ESIA Annex-9 SEP).

A Grave Relocation Procedure is presented in the appendices of the CHMP. The procedure to be followed is summarized below:

1- Identification of Need – Determining that a grave must be relocated due to project alignment or other compelling reasons.
2- Submission of Application – Submission of a formal request by the responsible parties (e.g., SPV, General Directorate of Highways, Municipality) to the relevant Metropolitan Municipality Cemetery Directorate.
3- Stakeholder Coordination – Engagement with relevant authorities including health institutions, religious representatives (e.g., imam), and families of the deceased.
4- Notification Stage – Written notifications will be delivered to the families of the deceased whose graves will be relocated.
5- Public Announcement (Mukhtars) – Public notices will be posted for 15 days in the offices of relevant mukhtars, ensuring coverage for all affected communities.

6- Local Newspaper Announcement – A notice will also be published in a local newspaper to ensure wider public awareness.
7- Selection of New Grave Site – The Metropolitan Municipality Cemeteries Directorate, in consultation with relevant authorities and affected families, will identify and approve a suitable new grave location within an officially designated cemetery area.
8- Start of Relocation – Within one week after the posting period, relocation works will commence under municipal supervision, with participation of a medical doctor, imam, and administrative staff.
9- Completion of Relocation – Due to the sensitive nature of the matter, all relocations will be completed as quickly as possible. The Metropolitan Municipality will coordinate the process and provide the necessary resources.
10- Support Services – If required, heavy machinery or other technical support may be requested from the Project Owner, and such requests will be met promptly.
11- Documentation and Reporting – All steps will be officially documented, including photographic evidence, grave identification, and new burial location, and reported to the competent authorities.

All necessary requirements are fulfilled within the competent authority, and the SPV and EPC will provide support if required.

Community engagement and respect for local sensitivities will be ensured throughout the process. By integrating both tangible and intangible cultural heritage considerations, the Project will ensure compliance with national legislation and international lender requirements.

XIII.5.4. Implementation of Commitments

The Project is committed to complying with both Turkish legislation and international standards on cultural heritage.

Ongoing engagement includes site investigations, training, and continuous consultation with the Antalya Regional Directorate for the Protection of Cultural Heritage, as well as coordination with the Antalya and Side Museum Directorates for excavation permits and monitoring. Commitments are summarized in Table XIII.13.

Table XIII.13 Cultural Heritage Commitments

No	Commitment	Project Phase	Responsible Party	Implementation Method	Monitoring / Reporting
1	Conducting archaeological baseline field surveys and notifying the Regional Conservation Board and Museum Directorate of the findings	Pre-Construction	Project Owner	Preparation of relevant documents	Follow-up by consultant and/or Project archaeologist, permit register tracking
2	Preparation of CHMP and Chance Find Procedure before construction begins	Pre-Construction	Project Owner	Preparation of relevant documents	Submission to contractors, implementation monitoring
3	Training of construction units and teams on actions to be taken in case of chance finds	Pre-Construction	Project Owner	Preparation of training materials and delivery of programme	Training records
4	In case of archaeological finds during construction, all works to be stopped and the Museum archaeologist informed	Construction	Contractor & Project Archaeologist	Staff training, site demarcation and marking	Incident reports, photographic and coordinate records

5	Establishment of protection buffer zones around designated archaeological sites	Construction	Contractor	Restriction of machinery access, installation of signage	Pre-construction survey reports or Site Monitoring Reports
6	Annual repetition of cultural heritage awareness trainings for new and ongoing staff	Construction & Operation	Project Owner & Project Archaeologist	Implementation of training programme	Training attendance lists, periodic reporting

XIII.5.5. Ongoing Statutory Engagement with the Regional Conseration Board (ARHB)

The Project Owner will maintain continuous statutory engagement with the Regional Conservation Board (ARHB) throughout the lifecycle of the Project. This engagement will be aligned with the Project schedule and will ensure that all cultural heritage management activities are conducted in compliance with national legislation and regulatory requirements.

The engagement programme includes:

- ***Pre-Construction Phase:*** Submission of baseline archaeological survey results to the ARHB for review and approval. Formal request for guidance and decisions on identified archaeological sites within the Project footprint (completed during ESIA process).

- ***Construction Phase:*** Regular updates to the ARHB on ongoing monitoring activities and chance find reports. Immediate notification of the ARHB in case of significant discoveries, followed by official correspondence and site inspections as required.

- ***Operation Phase:*** It is not expected that any cultural heritage assets will be affected during the operation phase, and no additional coordination with the Ministry of Culture and Tourism regarding cultural heritage areas will be necessary

The Project Owner will ensure that minutes of meetings, official correspondence, and ARHB decisions are systematically recorded and integrated into the Project's Environmental and Social Management System (ESMS). This structured engagement programme will guarantee timely regulatory approvals and ensure that cultural heritage management is fully aligned with the overall Project schedule.

XIII.6. Summary of Assessment and Residual Impacts

The impact assessment was conducted in accordance with the ICOMOS Guidelines for Heritage Impact Assessments, particularly those relevant to UNESCO World Heritage contexts. In alignment with IFC PS8, the assessment prioritized the preservation of cultural heritage in situ, especially in cases where sites are non-replicable or of significant value. As recommended in the archaeological baseline studies, the preferred mitigation strategy has been to avoid impacts by modifying the project alignment where archaeological sites were identified. Accordingly, the project design was revised in 15 locations to preserve cultural heritage resources in place, effectively minimizing potential residual impacts. This approach is consistent with the mitigation hierarchy outlined in PS8, which emphasizes avoidance, minimization, and in-situ restoration before considering relocation or compensation.

The studies being conducted by cultural heritage experts aim to identify unregistered sites in addition to the known registered sites. With effective implementation of the mitigation measures for conservation of these sites in accordance with this ESIA Report, it would be possible to reduce the significance of impacts to generally low levels. Cooperation with the regional conservation boards, implementation of Chance Finds Procedure and archaeological monitoring to be done by experts to be hired by the Project during the land preparation and construction phase is crucial for management of cultural heritage

corresponding to the Motorway route. The Project has already identified important sites. Therefore the Project is likely to contribute to the cultural and archaeological inventory of Türkiye and the still less known past of the region with these and possible new archaeological findings and the process to be conducted with the authorities within the framework of interdisciplinary archaeological studies.

Overall, the Project will be a benefit that contributes to the country's cultural and archaeological inventory through the implementation of appropriate techniques, methods and ESIA measures.

Assessments of archaeological and immovable cultural heritage will be conducted in accordance with the Impact Severity Classification Matrix in Chapter IV ("ESIA Methodology") (see **Error! Reference s ource not found.**).

XIII.6.1. Residual Impacts

Error! Reference source not found. summarizes the impacts caused by Project activities on the i dentified archaeological assets and residual impacts after mitigation measures are applied.

Land preparation and construction phase of the Project has the potential to cause vibration impacts as a result of activities such as blasting.

The assessment indicates that vibration from construction activities is likely to result in short term disturbance at nearby cultural heritage sites with varying sensitivities.

The residual impacts and assurance meaure of cultural heritage sites that can be potentially impacted by the recommended charge per delay of 10.82 kg have been assessed in Chapter XI.2.3 Table XI.36. However, these disturbances can be avoided and/or reduced by mitigation measures suggested above.

XIII.6.2. Monitoring

During the construction phase of the Project and road rehabilitation works, on-site archaeological monitoring should be conducted in order not to damage the listed identified cultural heritages.

During pre-construction surveys, the impact of construction activities on cultural heritage aspects will be considered, and vibration measurements will be repeated in areas deemed necessary. Vibration calculations will be updated to ensure that no damage will be caused to the archaeological heritage before construction begins.

Site- Specific Monitoring Commitments

Site-specific monitoring will be undertaken to assess and manage potential impacts on cultural heritage sites, particularly in relation to vibration effects from construction activities (e.g., blasting, piling, heavy vehicle movement). The following commitments apply:

- ***Baseline Monitoring:*** Prior to construction, baseline measurements of vibration levels must be conducted in the vicinity of known archaeological sites to establish reference conditions.
- ***During Construction:*** Continuous or periodic monitoring of vibration levels shall be carried out when works are undertaken near sensitive archaeological areas.
- ***Threshold Values:*** Monitoring must be based on national regulations and international best practice thresholds for vibration impact on built heritage.

- ***Blasting Activities:*** Where blasting near archaeological sites is unavoidable, it is recommended that the charge size be reduced. By conducting blasts with lower explosive quantities, the transmission of vibration impacts to archaeological sites shall be minimised. Details regarding the assessment of blasting and vibration impacts are provided in ESIA Chapter XI.2.3.

- ***Reporting:*** Monitoring results must be recorded, evaluated, and included in periodic cultural heritage monitoring reports submitted to the Project Owner and relevant authorities.

- ***Corrective Actions:*** If thresholds are exceeded, construction methods must be adapted (e.g., further reduction of blast charge, increased distance, or use of alternative equipment) to prevent damage to archaeological assets.

These monitoring commitments will be developed in consultation with the Antalya Regional Directorate for the Protection of Cultural Heritage and the Museum Directorate, to ensure full compliance with Turkish law and lender requirements.

Monitoring Methodology of Archaeological Sites and Cemeteries

In line with the requirements of the Cultural Heritage Management Plan (CHMP), regular monitoring provisions have been defined for archaeological sites, cemeteries and structural remains. In particular, cemeteries hold both tangible and intangible cultural heritage value, and therefore require monitoring during both the construction and operation phases.

Cemetery Areas

Because cemeteries represent both tangible and intangible cultural heritage, monitoring during the construction period is required in the sections where cemeteries are located. This requirement does not apply to every cemetery: for those listed sites where the route has been realigned, monitoring is not considered necessary and no specific commitments have been defined. For cemeteries located close to the final alignment, in order to ensure that community visits and commemorative practices are not adversely affected, regular post-construction monitoring is recommended at three- to six-month intervals.

Archaeological Sites

For areas identified in the CHMP as being adjacent to registered or potential archaeological sites, it is recommended that, where land acquisition has been completed, pre-construction investigations be undertaken. Prior to construction, machine-assisted trial trenching under the direct supervision of the Project Archaeologist may be carried out. In addition, within these sensitive areas, it is recommended that archaeological monitoring (watching brief) be implemented by the Project Archaeologist throughout the construction phase.

Relocated Structures (HRM-32)

Following the relocation of the structure known as HRM-32 to a secure location outside the Project impact area, monitoring at the new site is required. After the completion and restoration works, monthly surface inspections and reporting by the Project Archaeologist will be undertaken to track and record any potential construction-related damage.

Table XIII-14 Summary of the Assessments on Archaeological and Immovable Cultural Heritage

Affected Ecosystem Component	Historical Site Name	Location	Type	Registration Status	IFC PS 8 Heritage Value	Sensitivity / Value of the Resource / Receptor	Definition of Potential Impact (pre-mitigation)	Type of Impact	PS 8 Heritage Value	Impact Magnitude						Impact Significance (pre-mitigation)	Mitigation Measures		Significance of Residual Impacts

At the new relocation site, monitoring of the structure is recommended. The structure will be completed and restored; however, to guard against any potential damage caused by construction activities, monthly monitoring is recommended, to be carried out by the Project Archaeologist through surface inspections and reporting.		**Medium**

XIV. SOCIO-ECONOMIC ENVIRONMENT

This section examines how the Antalya-Alanya Motorway Project could affect the socio-economic environment of the region. It evaluates the impact of both the construction and operation phases of the Motorway separately. Desktop and field studies have been conducted to assess these impacts. This chapter covers the following:

- Assessment methodology and data sources,
- Baseline conditions of the socio-economic environment,
- Potential social impacts of the proposed project,
- Mitigation measures,
- Summary of assessment and residual impacts.

XIV.1. Assessment Methodology and Data Sources

XIV.1.1. Significance Criteria

The significance criteria for the impacts on socio-economic environment will be determined, as high, medium or low, based on the evaluation of magnitude of impact and sensitivity/value of the receptors/resources. The criteria previously presented in Chapter 4 (“ESIA Methodology”) will be used for the determination of the magnitude of impact on the socio-economic environment, while sensitivity/value criteria to be used in the scope of impact assessment is summarized in Table XIV.2

Detailed explanation of the sensitivity components for each resource/receptor is provided in the following “Baseline Conditions” section.

Evaluation of magnitude of impacts was based on the baseline conditions of the affected area and expert judgment (see Table XIV.1).

Table XIV.1 Impact Magnitude Criteria

Affected Resource/Receptor	Definition of Impact	Magnitude of Impact
Physical Displacement	Loss of residential structures requiring relocation of individuals or households due to land acquisition	High
	Effects on livelihood from livestock activities	Low
Restriction of Access to the Agricultural Lands and Greenhouses	Effects on livelihood from to the Agricultural Lands and Greenhouses	High
Infrastructures and Distribution of Utility Services	Effects on traffic and mobility	Medium
	Effects on infrastructures and utility services	Medium
Local Business	Physical displacement and loss of economic activities	High
Vulnerable Groups	Noise and Dust Emissions Generated by Construction Activities	High
Demographic Structure	Influence on local communities	Medium
Employment Opportunities	Opportunities for the local economy	Medium
Increase of Tension in Local Community	Increase of Tensions and Conflicts	Low

Table XIV.2 Criteria for Sensitivity/Value of Resource/Receptor

Affected Ecosystem Component	Definition of Impact	Sensitivity Criteria	Sensitivity/Value Level		
			High (3)	Medium (2)	Low (1)
Livelihood and Economic and Physical Displacement	Effects on livelihood from agricultural activities	• Settlements where agriculture is one of the main source of income • Settlements where access to agricultural areas will be restricted due to the Project • 10% of the total agricultural lands of the settlements • will be affected by the Project	3 Item	2 Item	0-1 Item
	Effects on Local Business	• Presence of businesses along or near the route • Businesses run by tenants or vulnerable groups • Disruption due to construction or reduced access	3 Item	2 Item	0-1 Item
	Effects on livelihood from livestock activities	• Settlements where livestock is one of the source of income • Settlements where access to pasture lands will be restricted due to the Project • Settlements where livestock activities are affected by the project	3 Item	2 Item	0-1 Item
Infrastructures and Distribution of Utility Services	Effects on traffic and mobility	• Settlement with a population ≥ 500 inhabitant • Settlements with single road access • Settlements benefiting from mobile schooling • Settlements with difficulties in access in winter	4 Item	2-3 Item	0-1 Item
	Effects on infrastructures and utility services	• Settlements with no municipal water supply • Settlements with electric cuts • Settlement with no sewage system	3 Item	2 Item	0-1 Item
Demographic Structure of Settlements	Influence on local communities	• Settlements experiencing out-migration or in-migration • Women ratio is above 52% • Presence of tensions and conflicts in the settlement	3 Item	2 Item	0-1 Item
Employment Opportunities	Opportunities for local economy	• Settlements with a population ≥ 500 inhabitant • Presence of industrial facilities within the 5 km buffer • Presence of organized industrial zones within the 5 km buffer • Settlements where unemployment is a major problem	4 Item	2-3 Item	0-1 Item
Increase of Tensions in the	Increase of Tensions and Conflicts	• Presence of tensions and conflicts in the	3 Item	2 Item	0-1 Item

Affected Ecosystem Component	Definition of Impact	Sensitivity Criteria	Sensitivity/Value Level		
			High (3)	Medium (2)	Low (1)
Local Community		settlement ● Presence of minorities ● Women ratio is above 52%			

**Sensitivity of this parameter will be taken as low, if none of the items on the left is applicable.*

XIV.1.2. Data Sources

Socio-economic investigations have two main components: desktop studies and field studies. Initially, information about the impact area and the settlements (such as land use and population data, etc.) was collected from various sources, including TurkStat. The sources used in the desktop studies are TURKSTAT 2023-2024, Antalya Provincial Directorate, Antalya Governorship. The field studies sources are ENCON Social Field Studies and GEM Resettlement Field Studies. The data obtained from site visits, and desk studies was used to plan and analyze social field interviews to be conducted along the planned Motorway route between June 3rd and June 6th, 2024.

In June 2024, Encon conducted a comprehensive four-day social field study as part of this process. The activities included:

Day 1: Interviews with professors from the Faculty of Agriculture and the Faculty of Tourism at Akdeniz University to gather academic and sectoral insights relevant to the project area.

Day 2: Headman interviews were conducted in Serik Central and Karataş neighborhoods. A focus group meeting was held in Serik Central, while another focus group took place in Taşağıl (Manavgat) with participants from diverse professions and age groups. Additionally, a separate focus group was conducted with elderly individuals representing vulnerable populations in Taşağıl.

Day 3: Multiple stakeholder focus group discussions occurred, including sessions with the muhktar of Ulukapı (Manavgat), road construction and site chiefs from the Manavgat Directorate of Public Works in Sanayi neighborhood, women from Ulukapı and Kalemler villages, and mixed groups of 9–14 participants from various professions and age ranges in Kalemler, Ulukapı, and Hacısali villages. Vulnerable elderly groups in Hacısali village were interviewed separately, and an individual interview was held with the president of the Manavgat Chamber of Agriculture.

Day 4: Interviews were conducted with the mukhtars of Karakaya (Manavgat) and Toslak (Alanya). Additional focus group discussions were held in the villages of Alara, Akdam, and Toslak (Alanya).

In addition, data used in this section is also based on the field report conducted with WSP on February, 2025, and the Resettlement Action Plan (RAP) Scoping Report prepared by GEM Sustainability Services and Consultancy Inc. for the Antalya–Alanya Motorway Project, dated May, 2025. This additional input helped to expand and cross-verify key data points gathered during earlier stages of fieldwork.

Three main tools used for quantitative and qualitative data collection during the social field study are described in questionnaires in Table XIV.3.

Table XIV.3Data Collection Tools

Tools	Description
Key Informant Interview	The key informant questionnaires were used as supporting tools for gathering information to make the research study more comprehensive. These questionnaires provided a way to verify information obtained from other data collection methods, ensuring the reliability of the data. Additionally, they helped gather preliminary information to support the use of other data collection methods. Within the scope of the project in total, the key informant questionnaires were applied in four (4) neighborhoods that are likely to be affected by the project: Serik/Merkez, Manavgat/Ulukapı, Manavgat/Karakaya, and Alanya/Toslak.. The main topics covered in the key informant questionnaires are given below: ● Population and Demographic Profile ● Socioeconomic Conditions ● Agriculture and Livestock ● Infrastructure Services ● Health/Education

Tools	Description
	• Facilities Related to Settlement Services, • Local Archaeological and Historical Monument Information, • Perceptions on the Project
Focus Group Interview	Focus group meetings are detailed interviews conducted with selective groups in accordance with an objective. The main purpose of the focus group meeting is to identify priorities and necessities of PAPs and vulnerable groups and also to identify direct and indirect effects of the Project. These meetings, which are important for taking stakeholders' thoughts, were applied by meeting moderator and an assistant. Within the scope of Supplementary ESIA studies, eight (8) focus group interviews were conducted with households and mukhtars in affected neighborhoods: Serik Merkez, Taşağıl, Kalemler, Ulukapı, Hacıisalı, Karakaya-Çakallar-Alara, Akdam, and Toslak-Telatiye (Konaklı)-Alara and vulnerable group interviews were conducted in those areas.
	Focus Group Interviews with Vulnerable Groups: In the case of reaching vulnerable/ disadvantaged groups (women-head households, unemployed young women/men, people with disabilities, older/young people in need of care, etc.), a separate semi-structured focus group study was conducted where possible with relevant questions. In the scope of ESIA studies, four (4) vulnerable groups' interviews were conducted.
Affected People / Key Stakeholders Interview	The interview gathered insights from key stakeholders, including NGOs, national / local organizations, and academic experts in the region. Five (5) unstructured interviews were conducted during the social field study to gather expert opinions and judgments.

The objective of the social field study (conducted on June 3-6, 2024) is to identify the area affected by the Project due to land acquisition and to assess the current socio-economic characteristics of the settlements. The interviews also aim to establish a database of measures and management strategies to evaluate potential social and economic impacts and prevent adverse effects on the socioeconomic living conditions in the settlements.

Socio-economic fieldwork is conducted to gain insight into the impact of settlements within a specific area and to collect both quantitative and qualitative data on the settlements being studied. Key informant and focus group interviews were conducted at intervals of approximately 20-25 km along the project route to gather a comprehensive understanding of the socio-economic environment. The goal was to cover about 15% of the road and surrounding corridor settlements.

Sample photographs from the field study are presented in between Figure XIV.1and Figure XIV.6. Additionally, in Figure XIV.7, a map shows the locations of the social field interviews were conducted.

XIV.2. Baseline Conditions

The project is carried out in Antalya, one of the provinces in West Mediterranean Region. It is a prominent city in Türkiye's Mediterranean Region, covering an area of approximately 20,177 km² with an average altitude of around 40 meters. The province comprises 77.8% mountains, 10.2% plains, and 12% rugged terrain. The Taurus Mountains cover three-quarters of the province's area, with many peaks exceeding 2500-3000 meters. Known for its stunning coastlines and rich cultural heritage, Antalya is considered Türkiye's capital city of tourism. It is the largest province in the Mediterranean region in terms of population. With a population of over 2.5 million (TURKSTAT, 2024), the GDP per capita in Antalya is around $14.828 (TURKSTAT, 2024). .

The province is well known for its tourism but also significantly contributes to agricultural production, exceeding the average by 4.3%. In areas where intensive agriculture is practiced, employment opportunities are abundant, and the province's agricultural production is essential for its diversity and market-oriented approach. Antalya is one of the most important citriculture provinces in the country, leading in orange production with a 30% share. Additionally, 80% of Türkiye's glass greenhouse area and 50% of the plastic greenhouse area are located in Antalya. The province also has a 90% share of cut flower production for the foreign market.

Regarding livestock activities, Antalya Province in Türkiye plays a key role in this area, with its significant population of small cattle. The province's landscape makes it conducive to goat farming, with goats being the predominant livestock. In the highland areas *(Yayla)*, goat and sheep breeding and some dairy cattle breeding are prominent, while dairy cattle and poultry farming dominate the coastal areas. While beekeeping primarily takes the form of migratory beekeeping, Antalya Province is an excellent region for wintering bees.

Specific indicators for the socio-economic development level of Antalya are presented in Table XIV.4. The table indicates that the number of automobiles per thousand people is approximately 178 for Türkiye on average. For Antalya, the number is 247, significantly higher than the national average. Another important indicator is the total electricity consumption per person, which are 3,348 KWh for Antalya and 3,386 KWh on average in Türkiye.

Table XIV.4 Indicators for Development Level of Antalya (TurkStat)

Indicators of Development Level	Türkiye	Antalya
Total Electricity Consumption per Person, 2023 (KWh)	3,390	3.736
Net Schooling Rate in Secondary School, 2022-2023 (%)	91.7	93.6
Level of Happiness by Provinces*, 2013 (%)	49.45	37.49
Number of Automobiles per thousand People (2023)	178	247
Number of Hospital Beds per Hundred Thousand People (2022)	307	282

**Note: Level of Happiness by Provinces is the proportion of surveyed population who declared that they are happy (Level 2)*

According to nomenclature of units for territorial statistics, Antalya is named as TR61 Level 2 territory together with Isparta and Burdur. Labor and Employment data and employment distribution by sectors are disclosed in Table XIV.5 and Table XIV.6, respectively below. According to data labor force participation rate in TR61 region is slightly higher than the Türkiye's average. While labor force participation in Türkiye is 53.3%, in TR61 it is more than 58.5%. Unemployment rate is significantly lower in TR61 region. The unemployment rate of Türkiye is around 9.4% and the rate is 7.2% in TR61. However, it is more than 7.4% in Antalya. As Table XIV.6 shows the sectoral distribution of employment in TR61 region, it is clearly seen that the agricultural employment is higher than the average. Compared to Istanbul (TR10), which is highly industrialized in Türkiye, agriculture and industry are in similar proportions in Antalya and its surrounding areas. While agricultural employment

is around 14.8% in Türkiye and less than 1 % in İstanbul, it is 16.1% of total employment in TR61 region.

Table XIV.5 Labor and Employment Data for 15+ Age Group (TurkStat, 2024)

Regions	Labor Force Participation (%)	Unemployment (%)	Non-agricultural Unemployment Rate (%) 2022	Employment Rate (%)
Türkiye	54.2	8.7	16,8	49.5
TR61 (Antalya, Isparta, Burdur)	58.1	5.8	-	54.7
Antalya	59	5.9	-	55.5

Table XIV.6 The Distribution of Employment by Sectors for 15+ Age Group (TurkStat, 2024)

Regions	Agriculture (%)	Industry (%)	Service (%)
Türkiye	14.8	27.3	57.9
TR10(İstanbul)	0.6	28.7	70.7
TR61 (Antalya, Isparta, Burdur)	16.7	16.6	66.7

XIV.2.1. Population

According to the data received from the Address-Based Population Registration System carried out in TurkStat, 2024, the population of Antalya Province is 2,722,103. The population of the province was 2,288,456 in 2015. Accordingly it can be said that the population of Antalya presents an increasing trend over the past years, with a population growth rate of 9.5 per thousand in 2024.

According to migration statistics, the net migration trend of Antalya is positive. In 2023, net migration in Antalya is 11.04 per thousand. Antalya province received the most immigrants from Konya. In addition, Antalya is a city that experiences both immigration and emigration from both domestic and foreign countries. Figure XIV.8 show the population change in years between 2015 and 2023 for Antalya.

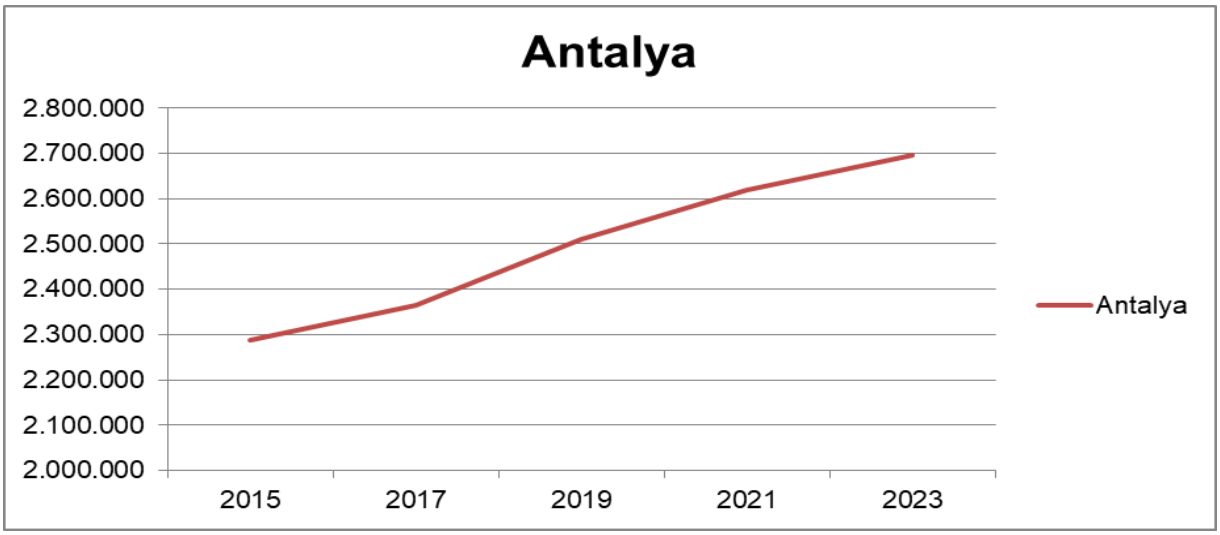

Figure XIV.8 Population Change of Antalya Province by Years (TurkStat, 2023)

The total fertility rate of Antalya province was 1.31 children per woman in 2023. By considering that the fertility rate of the province was 1.99 children per woman in 2015, it is understood that the fertility

rate has decreased within last years. In addition based on the results of TurkStat 2023; these rates are significantly lower than the fertility rate of Türkiye which is 1.51 children per woman.

When the age distribution of Antalya examined separately, it seems that the age group of 35-39 (8.41%) has the highest ratio within the population. Table XIV.7 and Figure XIV.9 shows the population distribution of Antalya province by age groups and gender.

Table XIV.7 Age Groups and Male-Female Population Distribution of Antalya Province (TUIK, 2024))

Antalya				
Age Group	**Female**	**Male**	**Total**	**Percentage (%)**
0-4	68,429	72,819	141,248	5.19%
5-9	91,667	97,114	188,781	6.94%

15-19	92,051	98,927	190,978	7.02%
20-24	88,453	94,316	182,769	6.71%
25-29	97,348	102,193	199,541	7.33%
30-34	99,791	100,414	200,205	7.35%
35-39	107,644	105,987	213,631	7.85%
40-44	114,214	114,809	229,023	8.41%
45-49	104,748	107,290	212,038	7.79%
50-54	96,521	98,003	194,524	7.15%
55-59	77,968	80,504	158,472	5.82%
60-64	70,870	69,631	140,501	5.16%
65-69	54,044	51,058	105,102	3.86%
70-74	38,990	35,035	74,025	2.72%
75-79	26,842	21,575	48,417	1.78%
80-84	15,658	11,951	27,609	1.01%
85-89	7,855	5,244	13,099	0.48%
90+	4,105	2,293	6,398	0.24%
Total	**1,351,933**	**1,370,170**	**2,722,103**	**100%**

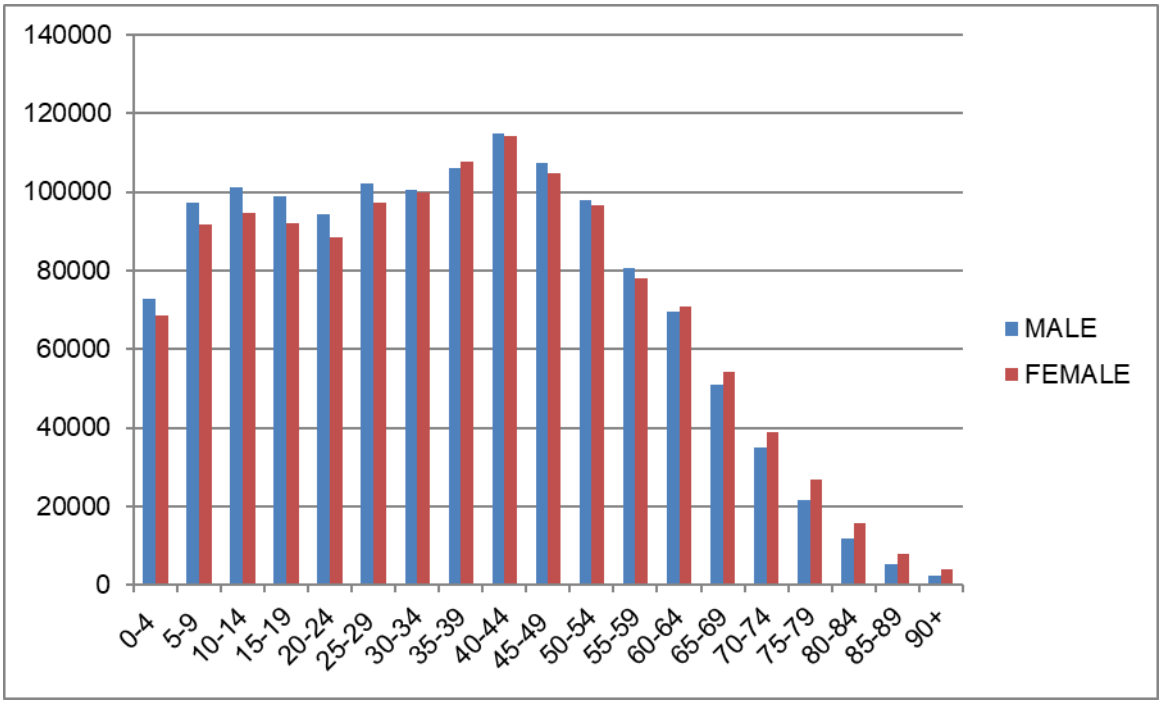

Figure XIV.9 Population of Antalya with Age Group and Gender Distribution (TUIK, 2024)

These population charts show that the population between the ages of 15-64 is predominant age group in the population of the city. As the total fertility rates show, the birth rates begin to decline yet the population growth rate of Antalya tends to increase. This indicates rapid immigration to Antalya.

Districts' populations of the province are given in Table XIV.8. According to the table, it is seen that Kepez is the most populous district in Antalya with 629,479 inhabitants, Muratpaşa (509,444 inhabitants), and Alanya (361,873 inhabitants) are the second and third and Manavgat (262,576 inhabitants) is the forth. On the other hand, İbradı (3,411 inhabitants) is considered to be the district with the lowest population.

Table XIV.8 District Populations of Antalya (TurkStat, 2024))

Districts of Antalya	Male	Female	Total	Percentage
Akseki	5,312	5,234	10,546	0.39%
Aksu	42,187	40,373	82,560	3.03%
Alanya	183,503	178,370	361,873	13.29%
Demre	14,291	13,523	27,814	1.02%
Döşemealtı	47,781	42,791	90,572	3.33%
Elmalı	22,174	19,679	41,853	1.54%
Finike	25,837	25,783	51,620	1.90%
Gazipaşa	27,975	27,387	55,362	2.03%

Serik	72,831	70,604	143,435	5.27%

XIV.2.2. Education

Education in Turkey is administered under the oversight of the Ministry of National Education and the Council of Higher Education. Since a 2012 reform, the country mandates 12 years of formal schooling, divided into three stages: primary (grades 1–4), lower secondary (grades 5–8), and upper secondary (grades 9–12). While public schooling is provided free of charge and enrollment rates at the primary and secondary levels have improved significantly over the past two decades, disparities persist in terms of quality, infrastructure, and access - particularly between urban and rural areas.

Overall literacy in Turkey stands at approximately 97%, with a notable closing of the gender gap over recent years. Nevertheless, regional variations in educational attainment remain considerable. Urban centers typically offer better access to schools, qualified teachers, and extracurricular services, while smaller rural settlements often contend with limited resources, fewer qualified staff, and logistical challenges in accessing higher-level schools. In many rural areas, secondary education is only accessible via bus transportation systems provided by provincial authorities.

Antalya Province, as one of Turkey's key coastal and tourism hubs, generally fares well in national education rankings. The province enjoys relatively high literacy levels - around 99% - and hosts a dense network of schools and vocational training centers, particularly in the city of Antalya. Higher education opportunities are anchored by institutions such as Akdeniz University, which serves tens of thousands of students including those in regional campuses like Alanya. However, despite these provincial-level strengths, intra-provincial disparities persist. In districts such as Serik, Manavgat, and parts of Alanya, particularly in villages along the proposed motorway corridor, field assessments indicate variable access to educational infrastructure and services.

These dynamics are further illustrated in the tables below, which provide disaggregated data on education levels by gender and age group for Antalya Province, as well as specific indicators from the districts of Serik, Manavgat, and Alanya. These tables help contextualize the educational landscape of the project-affected areas and inform potential mitigation strategies.

Table XIV.9 Educational Level of Male Population in Antalya by Age Group (TurkStat,2024)

	Primary School	22
	Vocational and Technical Upper Secondary Education	25
	Lower Secondary School (Middle School)	23

In Antalya Province, educational attainment levels show clear variation across age and gender groups. Among the male population (Table XIV.9), secondary and higher education degrees (middle school, high school, and university) are more common in the younger cohorts (ages 6–44), while the number of primary school graduates and individuals with no formal education increases significantly among those aged 45 and above. The number of postgraduate (master's and doctoral) graduates remains limited across all age groups and declines with age.

Among women, overall literacy and educational attainment are consistently lower than those of men across all age brackets. Illiteracy and primary-level education are especially prevalent among women aged 55 and over. In contrast, university and higher education degrees among women are primarily concentrated in the younger cohorts, with a significant drop observed in older age groups. The number of women with postgraduate degrees is markedly lower than that of men, further emphasizing the gender gap in educational outcomes (Table XIV.10).

These patterns suggest a strong age-related decline in educational attainment and highlight a persistent gender disparity across generations. The data indicates that women in Antalya, regardless of age, tend to have lower access to formal education compared to men.

According to 2023 data from the Turkish Statistical Institute (TurkStat), Antalya's total population stands at 2,722,103, with approximately 21% comprising individuals aged 5-19 - the core target group for formal education. This demographic structure has significant implications for educational infrastructure planning in the province.

Education statistics reveal that the average number of students per classroom is 22 for both primary and secondary schools, and 20 in vocational and technical secondary education (Table XIV.11). These figures suggest a generally manageable classroom density, although certain areas may face capacity pressure. The average number of students per school is 282 in primary, 263 in lower secondary, and 374 in upper secondary education, indicating the need for improved spatial distribution and planning of educational institutions.

The student–teacher ratio is highest in primary education at 17 students per teacher, potentially limiting individualized interaction at early stages of learning. Meanwhile, the number of students per class section ranges from 22 to 25 across all education levels, indicating a generally balanced classroom allocation.

Taken together, Antalya's demographic trends and existing education infrastructure suggest that the formal education system is largely capable of meeting current demand. However, continued population growth and regional disparities necessitate proactive measures - particularly capacity expansion at the primary level - to ensure equitable access and sustained quality across the province.

Educational Profile by Gender: Alanya, Manavgat, and Serik Districts

The educational profiles of Alanya, Manavgat, and Serik (Table XIV.12, Table XIV.13, Table XIV.14, Table XIV.15, Table XIV.16, and Table XIV.17) districts indicate a general trend of increasing educational attainment across generations and a narrowing gender gap, especially in younger cohorts. Illiteracy rates are relatively low overall but remain more prevalent among women in older age groups, particularly in Serik. This reflects historical barriers to female education access, which have gradually diminished in recent decades.

In all three districts, the number of individuals who are literate but have not completed any formal education is low and largely concentrated among the elderly, indicating improvements in the reach of basic education over time. Primary education levels are broadly comparable across districts, with slightly higher male representation in older age groups, reflecting earlier limitations in female enrollment and school completion.

Notably, women consistently outnumber men at the lower and upper secondary education levels, particularly in Alanya and Manavgat, suggesting enhanced access and retention for girls in recent decades. The trend is less pronounced but still visible in Serik (Table XIV.16, and Table XIV.17). At the tertiary level, including university and postgraduate education, male representation remains slightly higher, especially at the doctoral level. However, the increasing number of women attaining university and master's degrees across all three districts reflects shifting societal norms and improved educational opportunities for women.

These patterns collectively illustrate an upward trajectory in educational access and gender equity, although targeted interventions may still be necessary to address persistent disparities in higher education participation and adult literacy, particularly among women in older age groups.

XIV.2.3. Health Status

Aligned with IFC Performance Standard 4 (Community Health, Safety, and Security), this section presents a comprehensive assessment of the current health profile of Antalya Province, drawing upon statistical data from 2023. The analysis encompasses key factors such as demographic trends, healthcare infrastructure, service accessibility, health workforce distribution, emergency response capacity, and major health outcomes. This overview aims to evaluate the baseline conditions against which potential health-related impacts of the Project can be assessed, especially in terms of community vulnerability, system capacity, and service resilience.

Demographic and Dependency Characteristics

Antalya has a total population of approximately 2.7 million, characterized by a strikingly high urbanization rate of 99.1%, which is well above the national average of 88.8%. Only 0.9% of the population resides in rural areas, making it one of the most urbanized provinces in Türkiye. This reflects a densely populated urban structure, likely to affect both the demand for healthcare services and the spatial distribution of health infrastructure.

The province also exhibits a relatively young population profile. Individuals under the age of 15 make up 19.9% of the population, while only 9.7% are aged 65 or older. This results in a lower total dependency ratio (42.1%) than the national average (46.3%), particularly driven by a lower elderly dependency rate. These figures imply that the working-age population in Antalya carries a slightly lighter socio-economic burden, which can translate into increased healthcare utilization capacity and more predictable health-seeking behavior.

The demographic pattern indicates potential long-term stability in demand for maternal and child health services, alongside a future increase in demand for elderly care services. The table showing the relevant information is presented in Table XIV.18 below.

Health Infrastructure and Capacity

Antalya is currently served by 46 hospitals, offering a total of 7,545 beds, which equates to 28 beds per 10,000 residents - a figure slightly below the national average of 31.2. Despite this quantitative shortfall, the province compensates through quality: 89.4% of hospital beds are classified as qualified, reflecting modern equipment, adequate staffing levels, and compliance with national and international healthcare standards.

The number of intensive care unit (ICU) beds stands at 1,444, corresponding to 5.4 beds per 10,000 population, which is only marginally below the national rate of 5.7. These indicators suggest that the infrastructure is well-developed by national standards, particularly in terms of technical adequacy.

However, Antalya experiences significant seasonal fluctuations in population size due to its status as a major domestic and international tourist destination. These fluctuations - particularly during summer - can place severe stress on health infrastructure, especially ICU capacity, which is crucial for handling both trauma cases and complications of infectious diseases. The situation necessitates contingency planning, including surge capacity mechanisms for hospital admissions and emergency response. The table showing the relevant information is presented in Table XIV.19 and the spatial distributions are illustrated in Figure XIV.10 and Figure XIV.11 below.

Human Resources in Healthcare

Antalya's health workforce comprises 7,005 physicians, 6,921 nurses, and 8,635 other healthcare personnel, including technicians, paramedics, and support staff. The number of general practitioners (1,718) and specialist physicians (3,822) is indicative of a robust healthcare delivery model that combines primary and tertiary care services.

Nonetheless, when adjusted for population and seasonal influx, the healthcare worker-to-population ratio falls under pressure, especially during tourist seasons. Emergency departments, ICUs, and maternity wards are particularly susceptible to staffing strain. Strategic health workforce planning - including seasonal deployment of temporary personnel, training of local health professionals, and collaboration with national emergency medical services - can help alleviate this burden. The table showing the relevant information is presented in Table XIV.20 below.

Health Services Utilization

According to 2023 data, healthcare utilization rates in Antalya are high. Residents recorded over 14.4 million visits to primary healthcare facilities and 17.6 million visits to secondary and tertiary institutions, totaling more than 32 million medical encounters annually. On a per capita basis, physician visits reached 11.9, exceeding the national average of 11.4. Similarly, the per capita dentist visit rate is 0.70, slightly above the national rate (0.68).

These high rates of utilization indicate not only adequate access to healthcare services but also a high degree of trust in public health infrastructure. However, they also signal a need to ensure that infrastructure and human resources can keep pace with demand, especially in light of projected population growth and seasonal spikes. Preventive healthcare programs, such as regular screenings, vaccination campaigns, and family planning services, should be reinforced to reduce the burden on tertiary care. The table showing the relevant information is presented in Table XIV.21 below.

Emergency Health Services

Antalya operates 72 emergency care stations and is equipped with 118 ambulances. While this infrastructure appears adequate in absolute terms, a closer look reveals that each ambulance serves approximately 22,850 residents, which is considerably above the national average of 14,450 residents per ambulance. Similarly, each emergency care station serves about 37,448 people, again indicating potential service saturation.

Given the high rates of motor vehicle accidents during tourism seasons, combined with increased demand from non-residents, Antalya's emergency services may face delays in response times, limited coverage in rural or mountainous terrain, and reduced capacity for mass-casualty events. The table showing the relevant information is presented in Table XIV.22 below.

Mortality and Public Health Outcomes

Between 2020 and 2023, the leading causes of death in Antalya were cardiovascular diseases, neoplasms (cancers), and respiratory system diseases. COVID-19 significantly impacted mortality in 2020–2021, contributing to a temporary increase in total deaths, but its effect waned by 2023.

Notably, Antalya's infant mortality rate was 5.9 per 1,000 live births in 2023, which is substantially lower than the national rate of 10.0. Similarly, the under-five mortality rate stood at 7.7, compared to the national average of 14.5. These figures reflect effective maternal and child health services, access to immunization, and early disease detection mechanisms.

However, the region has seen increasing numbers of deaths due to chronic, non-communicable diseases, such as diabetes and neurodegenerative disorders, pointing to the need for expanded screening and lifestyle modification programs. Tables containing relevant information are presented between Table XIV.23 and Table XIV.26 below.

XIV.2.4. Socio-economic Baseline and Project-Affected People by Settlement

This section presents a detailed socio-economic baseline of the neighborhoods studied through key informant and focus group interviews, complemented by expropriation data and field surveys conducted between April and May 2025. The information highlights the primary economic activities and the extent of project impact on local livelihoods.

The total populations of the affected settlements are shown in Table XIV.27, with 2024 results announced by TurkStat. According to the 2024 data, the total population of the affected neighborhoods is 152,085 including district centers listed below.

In 2024, in Antalya, the Merkez neighborhood of the Serik District had the highest population with 17,969 residents, while the Sağırin neighborhood of the Manavgat District had the lowest with 163 residents. The population of the affected settlements, nearest motorway, and their proximity to the closest Project component are presented in Table XIV.27. Although not all are classified as settlement centers within the socio-economic area of influence, neighborhoods with land located within the expropriation corridor are also included in this table. Besides, within the corridor, distances are recorded as "0" if the Project Route passes directly over the closest building(s) of the settlement to the route.

Table XIV.27 Total Population of the Affected Settlements in Motorway's Corridor (TurkStat, 2024)

Districts	Neighborhoods	Nearest Approximate Motorway Km	Approximate Distance of the Settlement Center to Nearest Motorway Components (the nearest building) (m)	Direction with respect to Main Carriageway	Population (TurkStat, 2024)

	Elikesik	Alanya West Interchange Access Road	10	Northeast	2,212

Distances are given as "0" if the Project Route passes directly over the closest building(s) of the settlement to the route.

**There are not two separate neighborhoods as Evren and Seki in TurkStat, the population of Evrenseki Neighborhood is written in both Evren and Seki neighborhoods in the table.*

The information regarding household/family size is obtained with key informant questionnaire and the data is analyzed based on settlements separately. According to the data, the common average number of household size in all four settlements is 3.8 people. Accordingly TurkStat, the average size of household in Antalya is 2.94 people. The average household sizes of the four settlements are presented in Table XIV.28.

Table XIV.28 Average Household Sizes in the Surveyed Neighborhoods (Social Field Study, June, 2024)

Neighborhood	Population (TurkStat 2023)	(A) Population (According to the Muktars,2024)	(B) Number of Household (According to the Mukhtars,2024)	(A/B) Average Household Size
Merkez	17,583	20,000	5,000	4.0
Ulukapı	3,689	4,000	1,200	3.3
Karakaya	461	470	120	3.9
Toslak	3,666	3,700	1,000	3.7
Total	**25,399**	**28,170**	**7,320**	**3.8**

Economic Activities in Surveyed Settlements

In the four primary villages where key informant interviews were conducted - Serik/Merkez, Manavgat/Ulukapı, Manavgat/Karakaya, and Alanya/Toslak - agriculture remains the cornerstone of the local economy. Mukhtars and community members consistently emphasized agriculture as the primary livelihood source. Specifically, irrigated agriculture and greenhouse farming dominate economic practices, supplemented by small-scale livestock husbandry, which functions as a secondary income stream.

The region's strong ties to tourism also mean that many households engage in tourism-related activities as a tertiary income source, often seasonally. Additionally, retirement pensions provide a supplementary financial base, though the relative economic contribution of livestock and agriculture to household income remains limited in some settlements (Encon Social Field Study, June 2024). The distribution of income sources by neighborhood is summarized in Table XIV.29.

Table XIV.29 Main Sources of Income in the Surveyed Settlements (Social Field Study, June, 2024)

Neighborhood	Primary Income Source	Secondary Income Source	Tertiary Income Source
Serik/Merkez	Tradesperson/Crafts	Tourism	Merchant
Manavgat/Ulukapı	Greenhouse cultivation -	Small ruminant farming	Irrigated agriculture
Manavgat/Karakaya	Greenhouse cultivation	Irrigated agriculture	Tourism
Alanya/Toslak	Greenhouse cultivation	Irrigated agriculture	Tourism

Project-Affected People by Settlement

This section presents a detailed socio-economic baseline of the neighborhoods studied, based on data obtained through key informant interviews, focus group discussions, field surveys (conducted in June 2024 by ENCON and in April–May 2025 by GEM Sustainability Services and Consultancy Inc. for the RAP Scoping Report), and expropriation records.

Serik District

In Serik district, the Project mainly affects agricultural parcels and greenhouse areas. Larger-scale parcel impacts are concentrated in certain neighborhoods, while smaller and fragmented plots create a risk of leaving orphan land behind. The presence of informal or non-formal structures in some settlements adds complexity to the compensation process.

Table XIV.30 Affected Parcels in Neighborhoods of Serik

Settlement	No. of Affected Parcels	Houses	Greenhouses	Workplaces
Deniztepesi	25	2	4	0
Sarıabalı	136	14	13	0
Üründü	74	10	14	0
Belpınarı	5	-	1	0
Burmahancı	75	2	3	0
Cumalı	71	1	3	1
Aşağıçatma	17	4	3	4
Çandır	35	-	-	-
Kayaburnu	10	-	-	-
Aşağıkocayatak	2	-	-	-
Yukarıkocayatak	9	-	-	-
Dikmen	3			

Manavgat District

Manavgat district records the highest number of affected parcels overall, reflecting its strong dependence on agriculture and pasture-based livelihoods. Greenhouses and residential structures are significantly impacted in several settlements, indicating a high level of vulnerability among households reliant on land-based income. Some neighborhoods are further challenged by informal tenure arrangements, which complicate expropriation and compensation. In addition, areas with elderly populations and the presence of common or forest lands display heightened social sensitivity and limited livelihood alternatives.

Table XIV.31 Affected Parcels in Neighborhoods of Manavgat

Settlement	No. of Affected Parcels	Houses	Greenhouses	Workplaces
Çakış	42	7	3	-

Alanya District

In Alanya district, intensive horticulture and greenhouse production dominate the local economy. Alara, Çakallar, and Akdam stand out with the densest concentration of affected greenhouses. Toslak and Emişbeleni are also significantly impacted, highlighting the vulnerability of households reliant on agricultural livelihoods.

Table XIV.32 Affected Parcels in Neighborhoods of Alanya

Sewerage and Waste Disposal

Based on the information gathered from key informant interviews, both surface and groundwater are commonly used for domestic and agricultural purposes in the Project-affected region. Typically, there are no sewage systems in the neighborhoods, but septic tanks are used in Ulukapı, Karakaya, and Toslak neighborhoods. Domestic solid waste is collected by the Municipality in each neighborhood. This situation is similar in the settlements where focus group interviews were conducted. The different infrastructure systems in the Merkez neighborhood can be attributed to its proximity to the city center and its more urbanized demographic profile. This neighborhood is urbanized in terms of both economic activity and settlement. Table XIV.33 provides details on the sewage and waste disposal methods in the neighborhoods that were interviewed.

Table XIV.33 Sewerage and Waste Disposal Methods in the Neighborhoods (Encon Social Field Study, June, 2024)

Neighborhood	Domestic Water	Quality of Domestic Water	Usage of Drinking Water	Type of Sewerage	Waste Disposal
Merkez	Municipal Water/ Spring water	Potable	Bottled water	Sewage System	Collects by Municipality
Ulukapı	Groundwater	Potable	Bottled water/ Groundwater	Septic Tank	Collects by Municipality
Karakaya	Surface Water (Alara Stream)	Potable	Surface Water	Septic Tank	Collects by Municipality
Toslak	Groundwater	Potable	Bottled water/ Groundwater	Septic Tank	Collects by Municipality

XIV.2.5. Ecosystem Services Review

In accordance with PS6, the Project's impact on ecosystem services, and the benefits that local communities derive from these services, must be assessed. Ecosystem services are utilized for domestic consumption and recreational activities. This evaluation is conducted through an integrated analysis of both biodiversity studies and socio-economic data gathered in the ESIA. These findings provide a comprehensive understanding of how ecosystem services in the Project area are utilized and the potential effects of Project activities on these services.

Most considerations of ecosystem services, including IFC PS6, group them into the following four categories:

- **Provisioning Services (Type I)**: These are the goods or products obtained from ecosystems include resources such as agricultural land, pastureland, beekeeping, forest products, and fisheries, which local communities rely on for income, consumption, and medicinal use.
- **Regulating Services (Type II)**: These involve the contributions to human well-being arising from an ecosystem's control of natural processes, such as climate regulation, disease control, erosion prevention, and essential water resources that support the local population.
- **Cultural Services (Type III)**: These are non-material benefits that people obtain from ecosystems such as recreation, spiritual values, and aesthetic enjoyment.
- **Supporting Services (Type IV)**: These are natural processes that sustain other ecosystem services such as nutrient cycling and primary production that maintain the other services.

Socio-economic and biodiversity studies conducted within the scope of the ESIA process identify relevant ecosystem services as explained in Table XIV.34.

Table XIV.34 Ecosystem Service

Ecosystem Service	Sub-Category	Ecosystem Service on the Project Route	Status
Provisioning Services			
Food	Crops	Grains	Mostly for household consumption;
		Vegetables	Greenhouse production is practiced in some villages.
	Livestock	Large / small cattle	Livestock and greenhouse farming are significant sources of

		Poultry	income, with animal husbandry playing an important role in rural livelihoods.
		Grazeland	
		Fisheries	Not practiced currently, previously small-scale for household consumption. (Israeli carp introduction caused people to stop fishing.)
	Apiculture	Beehives	Practiced as a hobby; not a significant income source.
	Wild food	Citrus fruits	The most significant produce in terms of income generation (citrus fruits generating the most)
		Olives	
		Pomegranates	
		Mushroom, herbs	Collected mostly for household consumption (e.g., thyme, sage).
Biological raw material	Timber and other wood products	Firewood	Collected from local forested areas for household use; most villages have no forest, except Sarıabalı (forest village) and small patches in Burmahancı, Deniztepesi, Üründü.
Freshwater	Agricultural irrigation		Irrigation uses rivers, reservoirs, and groundwater. Drip and sprinkler systems are common, though some areas still use traditional methods.

XIV.3. Social Impact Baseline and Risk Analysis

This section provides a focused assessment of human rights, gender issues, vulnerable groups, displacement, and cumulative social risks in line with the International Finance Corporation (IFC) Performance Standards (PS1, PS5, PS7) and Equator Principles (EP4). These assessments aim to identify groups that may face disproportionate impacts from the Project and propose mitigation strategies tailored to their needs. Data collection was based on primary field studies, including key informant interviews, focus group discussions, and demographic analysis.

XIV.3.1. Human Rights Assessments

In accordance with IFC PS1 and PS2, the Project commits to upholding international human rights and preventing discrimination based on gender or social status. Women in rural settlements often participate in informal agricultural labor without compensation or legal protection, making them economically and socially vulnerable. Gendered constraints in mobility, access to credit, and land ownership compound these risks. To address these concerns, a confidential and inclusive Grievance Redress Mechanism (GRM) will be implemented, ensuring that women have equal access to complaints mechanisms and project benefits.

XIV.3.1.1. Methodology

The assessment of social impacts and human rights risks associated with the project was carried out using a mixed-methods approach that integrated both qualitative and quantitative tools. To establish a comprehensive understanding of the local context, a detailed desktop review was conducted, focusing on secondary data sources, national legal frameworks, and relevant international standards. This was complemented by multiple site visits to project-affected areas, where direct observations were made regarding local socio-economic conditions, settlement patterns, and daily community life. In addition, semi-structured interviews were held with a wide range of stakeholders, including women, elderly individuals, local leaders (muhtars), small business owners, and representatives of public institutions such as the General Directorate of Highways (KGM) and the Manavgat Municipality. Social baseline data collection was conducted by ENCON and GEM using participatory methods that are consistent with international best practices, including IFC Performance Standard 1. This multi-layered methodology was designed to ensure that the perspectives of vulnerable groups and key actors were meaningfully incorporated into the assessment.

Identification of Vulnerable Groups

In accordance with international social standards and based on field data, the following groups have been identified as vulnerable due to their exposure to disproportionate risks and limited capacity to cope with project-related impacts:

Table XIV.35 Identification of Vulnerable Groups

Vulnerable Group	Risk Factors	Potential Impacts
Children	Age-related dependence; lack of protection mechanisms	Increased exposure to risks during construction; potential interruption in schooling
Children with Special Needs	Physical/mental developmental challenges	Limited access to education and health services; heightened vulnerability in emergencies
Out-of-School Children	Poverty, migration, or lack of educational infrastructure	Long-term social exclusion; reduced livelihood opportunities
Elderly (75+)	Frailty, limited mobility	Dependence on local care and health services; high risk of social isolation
Elderly Requiring Care (65+)	Chronic illness, inability to live independently	Disruption of caregiving networks; increased reliance on social assistance
Illiterate Adults	Lack of literacy skills	Exclusion from consultations, grievance mechanisms, and decision-making
Persons with Chronic Illness (heart, diabetes, kidney, etc.)	Health fragility	Limited ability to adapt to displacement or livelihood changes; higher health expenditures
Other Serious Health Conditions (cancer, Alzheimer, etc.)	Severe medical dependency	Barriers to mobility and participation; dependence on specialized care
Persons with Physical Disabilities	Mobility and accessibility barriers	Reduced access to health, employment, consultation, and grievance systems
Persons with Mental Disabilities	Cognitive/behavioral limitations	Risk of exclusion from support services; dependency on caregivers
Unemployed (actively seeking work)	Lack of stable income	Increased economic insecurity and stress due to project impacts
Seasonal Agricultural Workers	Informal and insecure employment conditions; lack of social protection	Risk of labor rights violations; limited access to healthcare, housing, and safe transport
Dependence on Natural Resources	Reliance on small-scale farming, livestock grazing, and collection of forest products; limited livelihood diversification	Loss of agricultural income; reduced access to pastures and forest resources; heightened livelihood insecurity
Green Card Holders	Reliance on state health support	Limited access to private health or social protection mechanisms
State Aid Beneficiaries	Poverty, dependence on social transfers	High vulnerability to shocks; limited capacity for self-recovery
Informally Employed Workers (no social security)	Precarious employment	Risk of labor rights violations; exclusion from compensation systems
Economically Displaced Households	Loss of >20% of productive assets	Food insecurity, income loss, potential migration
Female-Headed Households	Gendered division of labor; limited resources	Economic insecurity; risk of exclusion from decision-making
Landless Households	No secure tenure	Exclusion from land-based compensation schemes
Low-Income Households (below minimum wage)	Chronic poverty	Persistent economic marginalization; dependence on aid
Migrant Households (e.g., Syrian, Afghan)	Unsecure legal status, mobility	Exclusion from grievance systems, labor markets, and social protection
Ethnic or Linguistic Minorities	Language barriers; underrepresentation in governance	Risk of exclusion from consultations and compensation; cultural marginalization
Semi-Nomadic Yörük Communities	Seasonal migration routes; dependence on livestock and pastures	Disruption of transhumance patterns; loss of traditional livelihoods and cultural identity
Households Previously Affected by Expropriation	Cumulative dispossession	Heightened vulnerability to further livelihood disruption

The table below summarizes key rights-holder groups potentially affected by the Project, along with associated human rights risks and potential adverse impacts. The mitigation measures are detailed in XIV.5. Additionally, labour rights and child labour-related human rights risks, potential adverse impacts and mitigation methods are also discussed in detail in Chapter XVI.

Table XIV.36 Rights-Holders and Potential Human Rights Risks

Human Right / Group	Potential Human Rights Risk	Risk Level	Potential Adverse Impact	Mitigation Section
Housing (Physical Displacement)	Right to adequate housing	High	Loss of shelter; violation of settlement rights	RAP; compensation; resettlement
Economically displaced households	Loss of >20% of productive assets	High	Food insecurity; livelihood disruption; forced migration	RAP; Livelihood Restoration
Landless households	Lack of secure tenure	High	Exclusion from land-based compensation schemes	RAP
Livelihood (Agriculture / Livestock)	Right to livelihood	High	Loss of income; restricted access to productive land	RAP; Land access; support measures
Seasonal agricultural workers	Informal and insecure employment	High	Labor exploitation; income loss; OHS risks	LMP; OHS Plan; RAP
Low-income households	Chronic poverty; below minimum wage	Medium	Dependence on aid; exclusion from markets	RAP; Livelihood Restoration
Informally employed workers	Lack of social security	High	Exclusion from compensation; vulnerability to exploitation	LMP; RAP
Dependence on Natural Resources	Right to maintain livelihoods linked to agriculture, grazing, and forest products	High	Loss of agricultural income, reduced pasture/forest access, livelihood insecurity	RAP; Livelihood Restoration
Vulnerable Groups (Participation & Equality)	Right to participation and non-discrimination	High	Exclusion from consultations; unequal access to support	SEP; outreach measures; grievance mechanism
Illiterate adults	Limited literacy skills	Medium	Inability to understand project information or grievance procedures	SEP; tailored communication
Women / female-headed households	Gender inequality; unpaid care burden	High	Discrimination; loss of informal income; limited participation	Gender Action Plan; RAP
Elderly / chronically ill / disabled	Frailty; mobility and health limitations	High	Social isolation; barriers to services; higher health costs	RAP; Community health services
Migrants & refugees	Insecure legal status; lack of documentation	High	Exclusion from grievance systems; labor exploitation; marginalization	RAP; SEP (language-sensitive outreach)
Ethnic or linguistic minorities	Language barriers; underrepresentation	Medium	Exclusion from consultations; risk of cultural marginalization	SEP (Kurdish/Arabic materials)
Cultural Rights (Nomadic / Traditional Communities)	Right to cultural identity	Medium	Disruption of Yörük migration routes; loss of traditional practices	RAP; Cultural heritage management; route preservation
Labor Rights (Workers)	Right to safe and fair working conditions	Medium	Risks to OHS, fair wages, and access to remedies	LMP; HR procedures; worker grievance mechanism
Health & Safety (Dust, Noise, Traffic)	Right to health and a safe environment	Medium	Respiratory and psychosocial health risks; traffic accidents	H&S Plan; noise/dust control; traffic safety

XIV.3.2. Vulnerability Assessment

In accordance with IFC Performance Standards (2012), identifying and assessing vulnerable groups is essential, especially in projects involving land acquisition and potential displacement. These groups often experience disproportionate and sometimes irreversible impacts due to pre-existing disadvantages. Therefore, they are specifically recognized and integrated into both the Environmental and Social Impact Assessment (ESIA) and the Stakeholder Engagement Plan (SEP).

A targeted vulnerability assessment was conducted via social field studies in eleven neighborhoods within or near the project area. The assessment framework followed nine IFC risk factors:

- **Gender**: Female-headed households, widows, and divorced women
- **Age**: Elderly individuals living alone or without caregivers
- **Ethnicity**: Ethnic minorities or culturally marginalized groups
- **Poverty**: Individuals dependent on charity or unstable income
- **Disability**: Persons with physical or mental disabilities
- **Health Status**: Chronically ill or housebound individuals
- **Literacy**: Individuals with little or no formal education

- **Dependence on Natural Resources**: Households reliant on agriculture, livestock, or forest products
- **Migratory Status**: Unregistered or undocumented migrants (e.g., Syrians, Afghans)

In accordance with international social standards and based on field data collected by ENCON and GEM, the following groups have been identified as vulnerable due to their exposure to disproportionate risks and limited capacity to cope with project-related impacts: elderly individuals, children, households with chronic illnesses, female-headed households, low-income families, illiterate adults, state aid beneficiaries, and seasonal agricultural workers. The table below provides a summary of the identified vulnerabilities across the affected districts and neighborhoods within the Expropriation Corridor. While this table presents a qualitative overview of the key vulnerabilities observed at the neighborhood level, detailed quantitative data regarding the number of households and individuals under each vulnerability category are comprehensively presented in the Resettlement Action Plan (RAP). In addition, specific findings on Migratory Status and Nomadic Populations (Yörük Communities) have been presented separately below the table, as the former draws on both ENCON fieldwork and data from the Refugees Association, while the latter was identified during the desk study stage.

Table XIV.37 Vulnerable Groups in the Expropriation Corridor

District	Neighbourhood	Vulnerable Groups
Serik	Deniztepesi	Other significant health issues, Economically displaced household
	Sarıabalı	Physically displaced household, Economically displaced household, Landless household, Household s who lose more than 20 percent of their total productive area, Women-headed household, Low income household, Unemployed (Although looking for a job), Chronic diseases, Children of school age who do not attend school, Illiterate, Mental Disability/ Issues, People who do not speak and/or understand Turkish
	Çandır	Economically displaced household, Household s who lose more than 20 percent of their total productive area
	Cumalı	Economically displaced household, Chronic diseases, Physical Disability, Mental Disability/ Issues
	Burmahancı	Economically displaced household, Landless household, Low income household, Household s who lose more than 20 percent of their total productive area
	Üründü	Economically displaced household, Households who lose more than 20 percent of their total productive area, Advance Old Age (over 75), Elderly (over 65) in need of care, Illiterate, Physical Disability, Chronic diseases
Manavgat	Çakış	Economically displaced household, Low income household, Households who lose more than 20 percent of their total productive area, Elderly (over 65) in need of care, Illiterate, Physical Disability
	Taşağıl	Economically displaced household, Landless household, Household s who lose more than 20 percent of their total productive area, Women-headed household, Low income household, Advance Old Age (over 75), Elderly (over 65) in need of care, Illiterate, Physical Disability, Chronic diseases, Other significant health issues
	Gündoğdu	Economically displaced household, Low-income households, Chronic diseases
	Hocalar	Economically displaced household, Landless household, Household s who

District	Neighbourhood	Vulnerable Groups
		lose more than 20 percent of their total productive area, Low-income households, Elderly (over 65) in need of care, Illiterate, Chronic diseases, Unemployed (Although looking for a job)

	Odaönü	Economically displaced household, Low income household, Households who lose more than 20 percent of their total productive area, Chronic diseases
	Karakaya	Economically displaced household, Landless household, Low income household, Households who lose more than 20 percent of their total productive area, Significantly affected by expropriation of other past projects, Advance Old Age (over 75), Elderly (over 65) in need of care, Illiterate, Physical Disability, Chronic diseases, Seasonal agricultural workers
Alanya	Alara	Economically displaced household, Women-headed household, Landless household, Households who lose more than 20 percent of their total productive area, Advance Old Age (over 75), Illiterate, Chronic diseases
	Çakallar	Economically displaced household, Landless household, Households who lose more than 20 percent of their total productive area, Advance Old Age (over 75), Elderly (over 65) in need of care, Illiterate, Chronic diseases, Mental Disability/ Issues, Beneficiary of governmental aid
	İncekum	Economically displaced household
	Türkler	Economically displaced household, Landless household, Low income household, Households who lose more than 20 percent of their total productive area, Chronic diseases, Physical Disability
	Emişbeleni	Economically displaced household, Landless household, Households who lose more than 20 percent of their total productive area, Illiterate
	Toslak	Economically displaced household, Landless household, Low income household, Households who lose more than 20 percent of their total productive area, Elderly (over 65) in need of care, Illiterate, Chronic diseases, Physical Disability, Mental Disability/ Issues, Employed without social security
	Telatiye	Economically displaced household, Households who lose more than 20 percent of their total productive area, Chronic diseases
	Elikesik	Economically displaced household, Landless household, Low income household, Illiterate, Chronic diseases, Seasonal agricultural workers

Migratory Status: Field research conducted by Encon in June 2024 identified Syrian citizens and other migrant groups under temporary protection, particularly in the Central District of Serik. Greenhouse owners in Serik, Manavgat, and Alanya districts have stated that they employ migrant workers. Seasonal workers are primarily Afghan and Syrian nationals. According to the RAP Report, registered and unregistered migrant workers are present in the neighborhoods of Emişbeleni, Aşağıçatma, Evren (registered), Toslak, and Çakış. According to the Refugees Association, as of May 2025, there are approximately 6,839 Syrians residing in Antalya. Tensions toward refugees have been reported, particularly in Serik. Project materials will be provided in Arabic to support inclusive participation. Additionally, necessary information will be communicated specifically by CLOs.

Nomadic Populations (Yörük Communities): Seasonal nomadic groups such as the Yörüks were identified along migration routes passing near the project alignment (~1,200 m away at times). Semi-nomadic communities are also present in Toslak, Ulukapı, and Karakaya. These groups often:

- Rely heavily on livestock grazing and pasture access
- Have low literacy rates and limited access to health services
- Are excluded from formal consultation due to their mobile lifestyle

To support them, the project will incorporate culturally sensitive engagement methods, preserve grazing corridors where feasible, and consider compensation or assistance through the Livelihood Restoration Plan.

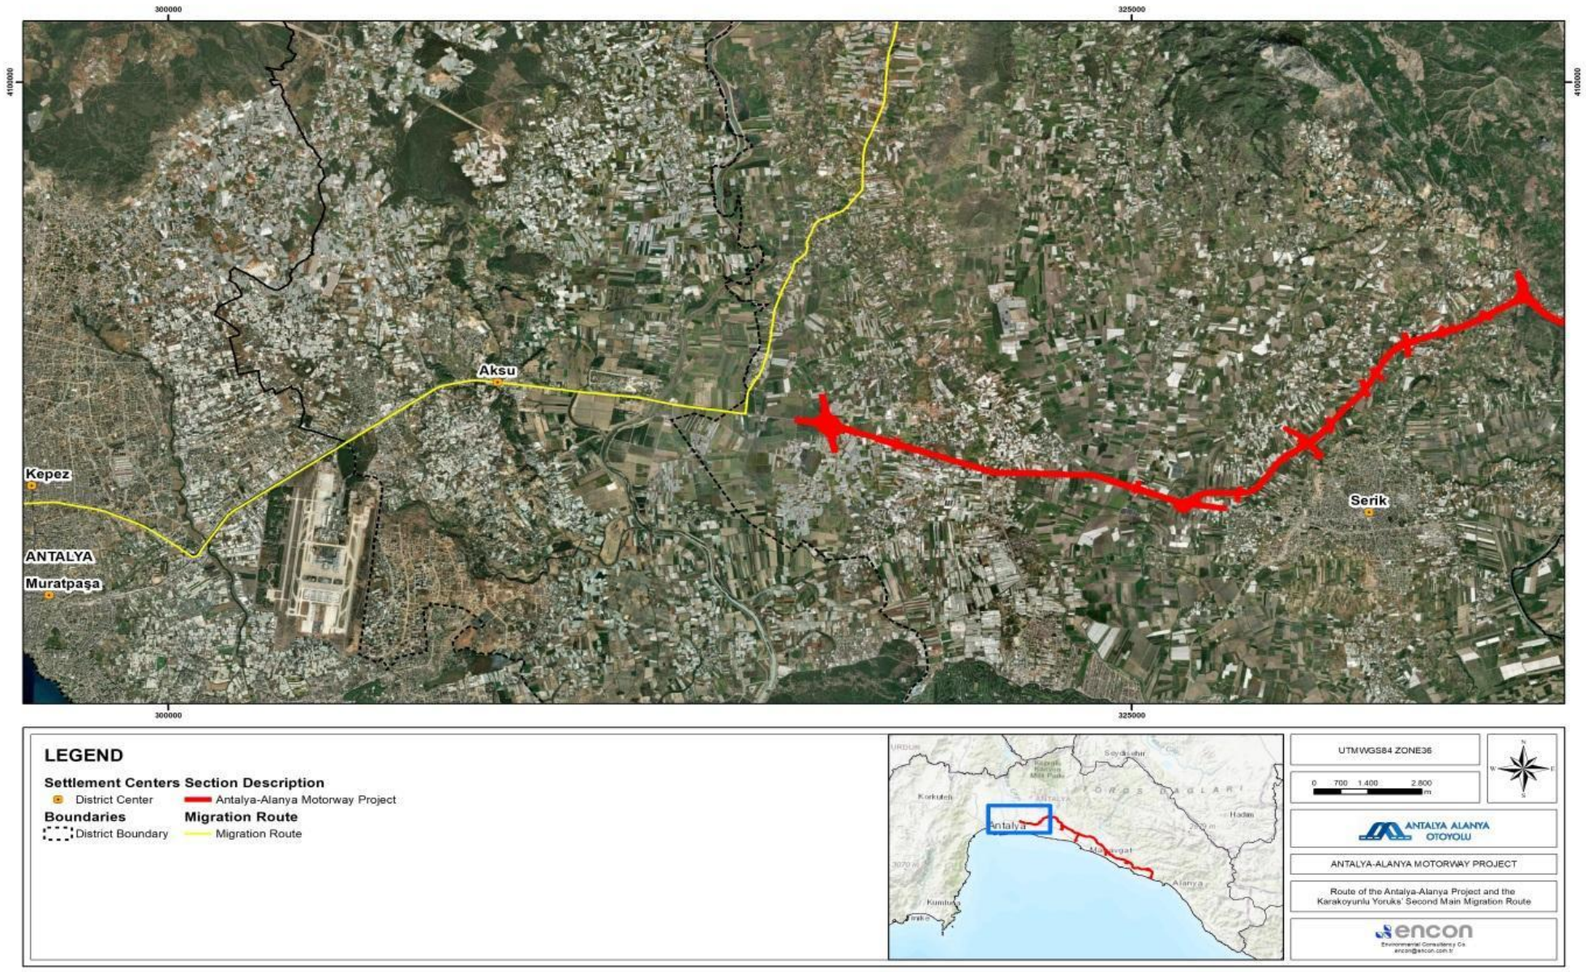

Figure XIV.13 The Migration Pathway of Nomads in the Region

XIV.3.3. Gender Assessment

The gender assessment for the Project has been conducted in line with international best practices, including the IFC Performance Standard 1 and 2, as well as relevant national policies promoting gender equality. The methodology is designed to identify and assess potential gender-specific impacts throughout the Project lifecycle and to inform appropriate mitigation and enhancement measures.

The gender assessment for the Project was conducted using a multi-faceted methodology aligned with international standards, aiming to identify gender-specific risks and opportunities throughout the Project lifecycle. As part of baseline data collection, available gender-disaggregated data on education levels, labor force participation, and access to services within the Area of Influence (AoI) were reviewed. This was supplemented by secondary data from national statistics and reports from NGOs working on women's rights and gender-based violence in Türkiye.
